SOME FACTORS TENDING TOWARD ADEQUATE INSTRUCTION IN NERVOUS AND MENTAL DISEASES*

WILLIAM W. GRAVES, M.D.
Professor, Department of Nervous and Mental Diseases, St. Louis University School of Medicine
ST. LOUIS

The earnest effort on the part of the Council on Medical Education of the American Medical Association to raise the standard of medical education in the United States has met a gratifying measure of success. Its beneficent influence has been revealed in several directions. One of its achievements is the formulation of a "standard curriculum" through a subcommittee of one hundred medical educators. This curriculum, however, is intended to be entirely educational and suggestive and the "Council does not consider it in the interest of true progress in education that any standard curriculum whatever shall be uniformly adopted by all medical schools." Even though it was not proposed as a fixed standard, formulated as it was by one hundred prominent educators, it receives general recognition and is bound to be used as a model and thus to have definite influence on medical education in this country.

Medical curriculums are doubtless formulated on the fundamental principle that time and place allotted to a given branch should be proportionate to its importance in the production of competent practitioners of medicine. When we consider the intimate and reciprocal relations of the nervous system with other systems and organs of the body, its highly specialized structures and functions, and, moreover, the conditions and diseases which affect it both primarily and secondarily, the importance of adequate consideration of the nervous system in health and disease in any scheme of medical education becomes obvious.

Does the standard medical curriculum and do the medical schools of this country allot to neurology and psychiatry time and place proportionate to the importance of these branches? This is a serious question and one well worthy of consideration by medical educators generally and particularly by those professing knowledge of the subjects identified with this Section. It would seem that we are justified in answering the question in the negative when we consider the lack of interest by medical students in the clinical aspects of neurology and psychiatry as contrasted with the definite interest in the anatomy and physiology of the nervous system during the first two years of medical school work; the almost universal feeling of incompetence in the recognition of nervous and mental diseases by recent graduates; the apathy, and I may say indifference, toward the easily discernible signs of mental and nervous diseases by medical men generally (excepting by those specializing in these branches and not always by these); the ignorance displayed in our courts concerning them, and the existence and growth of the several "isms" and "cults" which thrive on the credulous, the unbalanced and the nervous.

If we seek to determine the reasons for this state of affairs, two possibilities are at once suggested; either little is definitely known about the nervous system and its diseases or else our medical teaching is inadequate. Surely no one will contend that the general indifference toward neurology and psychiatry existing among the rank and file of the medical profession is due to the state of knowledge concerning these branches. The present state of knowledge is indicated in modern text-books and current literature. Modern text-books on anatomy and physiology devote, respectively, approximately one-fifth and one-third of their pages to the nervous system. In modern text-books on practice fully one-fourth of the total space is allotted to diseases of the nervous system, not including psychiatry, and numerous special works, monographs and journals are devoted to the nervous system and its diseases. Approximately 10 per cent. of the articles published in several leading journals devoted to general medicine, including The Journal of the American Medical Association, are on neurologic and psychiatric subjects. Certainly, the volume of literature does not indicate that little is kown about the nervous system and its diseases. Moreover, the state of knowledge in these fields approaches a degree of exactness comparable to that in other fields. In no other fields are the reciprocal relations between structure and function better known, exemplified and utilized. We have, therefore, for neurology and psychiatry the firmest foundations in the known facts of anatomy and physiology of the nervous system.

Medical knowledge in general is in a state of flux and not all is known in any department that may yet be known. There are many unsolved problems in connection with neurology and psychiatry. But the state of our knowledge concerning the nervous system and its diseases coupled with existing methods of the clinic and the laboratory is so definite that the recognition of, and the differentiation between, the organic and so-called functional diseases are at least among the possibilities of medicine.

The present degree of indifference on the part of the profession generally toward neurology and psychiatry, is, therefore, not due to the inadequacy of knowledge at the present time; hence it would seem that we are justified in concluding that these subjects are not adequately presented in our medical schools.

---

* Chairman's address, read before the Section on Nervous and Mental Diseases, at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, June, 1914.

If instruction in neurology and psychiatry is inadequate—that is, not proportionate to the importance of these branches—let us direct our attention to some of the factors which appear to be at the bottom of the difficulty. We must recognize defects before we may hope to eliminate them. The chief defects in instruction in our medical schools in these branches will probably be found, first, in instructors and methods; second, in correlation of structures and functions of the nervous system with clinical neurology and psychiatry; third, in correlation of neurology and psychiatry with other clinical branches; and fourth, the time devoted to these subjects and their place in the curriculum.

I. INSTRUCTORS AND METHODS

"Efficient teaching requires three essential conditions: (1) complete mastering of the subject-matter on the part of the teacher; (2) a clear notion of the aim of the teaching, and (3) well chosen methods of accomplishing the aim" (Jackson[1]). Adequate instruction in neurology and psychiatry can be expected only from those who possess adequate knowledge of the structures, functions and diseases of the nervous system, who are trained in the methods applicable to the investigation of these and who are otherwise thoroughly grounded in the principles of biology and medicine. In the ranks of those who profess knowledge in neurology and psychiatry there are many who approach this ideal. On the other hand, there are many incompetents, some of whom have come from general practice, some directly from medical schools with or without a hospital year or two and not a few who "drift in" after unproductive months or years in sanatoriums and state hospitals. Whether "drifting in" from general practice, directly from the medical school or from the state hospital matters little—the fact remains that such men, without additional training, are not equipped, are not qualified to teach either neurology or psychiatry. And from the unequipped in the ranks come the instructors in these branches in not a few medical schools in this country. The demand for well-equipped instructors in these branches far exceeds the supply. This is another point in evidence of the inadequacy in instruction in the past and emphasizes the importance of better teaching in the future. Better teaching will awaken interest in the student body, and from this interest will come the development of more men better qualified to teach the current knowledge of the subjects they profess—"sifting, analyzing, assorting and laying down principles."

In the medical schools of this country with but few exceptions neurology and psychiatry are combined in one department, and in about one-half the schools this department is an independent department. The importance of these branches and their correlations with each other as well as with every other department of medicine are sufficient reasons for combining them in one department; but there is no valid reason why the two subjects should be taught by the same instructor as is the rule. While it may be possible for one to practice neurology and psychiatry, the volume of previous work in either branch is so great that "sifting, analyzing, assorting and laying down principles" cannot be well done by one man in both branches at the same time. Therefore, it would tend toward more efficient instruction in these subjects if certain instructors in the department confine their energies to neurology and others to psychiatry, because independent instructors could best induct the students into the principles and the practice of the special methods in each branch. The aim of instructors in these branches in the medical school should not be to make "specialists" but to aid the student in the acquirement of such knowledge as will better enable him to recognize disease in general and particularly diseases of the nervous system.

Specialism falls short of its obligations to, and ceases to become a part of, general medicine when its methods of investigation cannot be understood and utilized excepting by the specialist himself. The more specialized clinical branches best meet their obligations to medicine when they contribute their portion in aiding the student to have a better appreciation of the patient as a whole individual. In this age of specialism and short cuts to diagnoses the whole individual is often lost to view. Indeed, he is nowhere more completely buried than in the clinical years in our medical schools. During the fundamental years he is a commanding figure; he awakens interest in the student body; he dominates it. During the clinical years he shrinks into darkness and for many is lost beyond recall—crushed by the weight of specialism, crammed into the tired brain of the student body. The general advance in medical knowledge should render the appreciation of the concept of the patient as a whole individual more thorough, more complete than ever before. That such appreciation is actually less must be due in part to the dominance of specialized branches in teaching during the clinical years. The concept of the whole individual should dominate medical teaching not only in the fundamental but also in the clinical years. The true relations of the parts with the whole should never be lost sight of for a moment.

Vocalized text-book chapters — didactic work — should be largely eliminated; and ready-to-use diagnoses—clinical lectures—should be restricted because neither develops the self activity of the student in the recognition of health and disease. Yet neurology and psychiatry are taught mainly in these ways in most medical schools in this country. This is, probably, one of the most serious defects in instruction in these branches, but the defect is in the instructors and not in the branches themselves.

To train the student in the recognition of disease is the primary aim of medical education. The recognition of disease must precede prevention, and it is the very foundation of all rational treatment. Let there be less teaching of nervous and mental diseases and more of the methods of recognizing them. Let the instructors be counselors and guides and not merely the distributors of ready-made diagnoses. Let their activities be expended mainly in guiding the student in accurate data getting, the very foundation of accurate diagnoses. Let the instructors supply the material made up of normal, functional, organic and mixed states. Let the student do the work and his interpretation of the accumulated data will follow as a natural sequence. It is not to be expected that either his data or his interpretations will always be correct either during his student days or at any time thereafter, but earnest effort in either direction at any time will stimulate his interest and develop his self-activity and his self-criticism. Let the student be guided in simple yet accurate methods in getting data concerning family, personal and present history; and concerning sensory, special sense, mental, motor, reflex, vasomotor, trophic and autonomic reactions and he will secure for himself a working knowledge of neurology and psychiatry—knowledge which he can apply to a better elucidation of the clinical problems in other departments of medicine because an appreciation of the reactions of the nervous system in health and disease gives him a clearer insight into the individual as a whole.

---

II. CORRELATION OF *STRUCTURES AND FUNCTIONS* OF THE NERVOUS SYSTEM WITH CLINICAL NEUROLOGY AND PSYCHIATRY

Since knowledge of physiology, anatomy, pathology and psychology finds constant application in the interpretation of the symptomatology and physical signs of nervous and mental diseases, students must be able to correlate knowledge of these fundamentals with clinical data. Instruction in each of these, excepting in psychology, is doubtless adequate in the better medical schools. The recognition of the necessity of obligatory work in psychology will doubtless result in speedily remedying this defect in instruction. In the recent Report of the Committee of the American Psychological Association on psychology and medical education[2] it is stated that *in the first two years fully* 10 per cent. and probably as much as 15 per cent. of the total time is devoted to the study of the nervous system, that is, anatomy, physiology and pathology. The same report disclosed the fact that very few schools are actually giving instruction in psychology though "it appears to be the preponderating opinion both of the best schools and of the schools as a whole, that some instruction in psychology is necessary so that students may understand the mental side of their patients, not only of those who are to be dealt with as insane, but also of many who never reach the extreme conditions which warrant their being sent to an institution for nervous or mental diseases."

In order that knowledge of the fundamentals and of the clinic may be correlated, the principle of relative values should receive greater consideration by instructors in these branches. E. P. Lyon[3] has recently indicated the working of this principle thus: "We should do our best from the multiplicity of facts to supply those most likely to be valuable to our students." Doubtless much could be eliminated in the fundamental and clinical years if instructors would give mainly those facts most likely to be of value in the clinic. If mainly usable facts were taught both in fundamentals and in the clinic, the principle of correlation would become more effective because more simplified. But the instructors in the fundamentals are not as a rule trained clinicians; hence they teach most of what is known about their subjects and necessarily much of little practical value for the clinical years. Moreover, the time which elapses between instruction in the fundamentals and in the clinic is so great that the student will have forgotten much of the useful with the useless knowledge acquired in his first semesters.

To further the teaching of the practical in the fundamentals, conferences should be held between the instructors in the anatomy, physiology and pathology of the nervous system and those in the clinic, and a definite plan of instruction outlined. A few type cases demonstrated in the classes of physiology and anatomy will serve to obviate the evil effects of time on the principle of correlation between the fundamental and clinical years. Neilson[4] has recently asked the pertinent question, "Would it violate any sane principle to have the neurologist give a lecture and demonstrate a case of tabes or one of transverse myelitis when the physiology of the tracts of the cord is studied?" This principle of correlation will be further strengthened by the incorporation of two definite recapitulation courses given by clinicians in the beginning of the clinical years: *one consisting in a review* of anatomy, physiology and pathology of the nervous system given by the instructor in neurology, the other in a review of psychology given by the instructor in psychiatry.

III. CORRELATION OF NEUROLOGY AND PSYCHIATRY WITH OTHER CLINICAL BRANCHES

The intimate and reciprocal relations of the nervous system with other systems and organs of the body are the fundamental relations which correlate it with the clinic, which prevent narrowness in those possessing a working knowledge of its structures, functions and diseases, and which render a consideration of its several activities indispensable in the study of the patient as a whole individual. Neurology and psychiatry are *unfortunately considered by curriculum* makers and the profession generally as belonging to the narrowest and least important of specialties, when in fact these branches are special mainly in methods of investigation. The problems connected with them are identical with those of general medicine. A working knowledge of the structures, functions and diseases of the nervous system finds constant application in the study of the individual patient, whatever his disease may be. Hence adequate instruction in neurology and psychiatry is not only dependent on the working of the principle of correlation in these branches between the fundamentals and the clinic, but it is equally dependent on adequate instruction in, and correlation with, other branches of medicine.

Adhering to the principle of relative values, it seems that the kind of instruction most likely to be of value to the student in the clinical years would be in the technical methods utilized in the several clinical branches in the recognition of health and disease. Instruction in these methods, as already indicated, has not been adequate in the department of nervous and mental diseases, and what is true of the instruction in these branches is in a large degree true of instruction in other clinical branches. As a part of the routine examination of the nervous system, for example, the use of the ophthalmoscope, perimeter and laryngoscope, and methods in discerning pupillary anomalies and in determining the functional activity of certain cranial nerves find constant application; yet it is notoriously true that the instructors in the branches to which these methods primarily belong seldom give them adequate consideration. Now adequate instruction in these methods by the department to which they primarily belong aids in developing the self-activity and proficiency of the student not only in these departments but also in other departments. The use of the ophthalmoscope, for instance, is not merely confined to the recognition of certain diseases of the eye but its use is indispensable in internal medicine, pediatrics, surgery, neurology and psychiatry.

[4] Neilson, C. H.: The Teaching of General Medicine, New York Med. Jour., 1914, xciv, 1189.

If methods in the use of a single instrument can find such broad application, how very important it appears that students should be taught methods in data getting in each department for the general recognition of disease and for the correlation of the knowledge in one department with that of every other. The correlation of neurology and psychiatry with other clinical branches can be accomplished by the student only when instruction in method is adequate in each department. Let this obvious principle in pedagogy be practiced, and a working knowledge of the nervous system in health and disease will be within the reach of the future graduates in medicine.

IV. THE TIME DEVOTED TO THE SUBJECTS AND THE PLACE IN THE CURRICULUM

If it be a fundamental principle in curriculum making to allot time and place to a given branch in proportion to its importance in the production of competent practitioners, what place and what time should be alloted to neurology and what to psychiatry in the clinical years? Remembering that each branch deals with the same underlying structures and similar reactions of the nervous system; that in a neurologic condition the mental reactions and in a mental state the neurologic reactions should always be studied; that a study of the individual patient whatever his disorder may be cannot be complete without investigating the several activities of the nervous system and that mental states are quite as numerous and important as neurologic states, then it would seem that instruction in both branches should commence in the very beginning of the clinical years, and should be allotted equal time, given in parallel courses and continued throughout these years.

However great may be the ability of the instructors in the fundamental and the clinical branches and however excellent their methods may be, if instruction in neurology and psychiatry is confined mainly to the fourth year, as is now the case in most of the medical schools in this country, the student cannot acquire a working knowledge of these branches. On the other hand, if instruction in these branches be given from the beginning to the end of the clinical years, the student will be able to correlate them with all other clinical branches. Unless the nervous system is to continue to be considered a thing apart in the concept of the whole individual, as is now the case in most of the medical schools in this country, instruction in the recognition of its reactions in health and disease must logically begin at the moment the student receives his first conceptions in clinical medicine and continue throughout the clinical years.

The standard medical curriculum allots 150 hours in the clinical years, 60 hours in the third and 90 hours in the fourth year. Provision is made for instruction in neurology in the third and fourth years, but psychiatry is placed in the fourth year and is given only 30 hours—15 hours under "Clinical Conferences" and approximately 15 hours under "Didactic Lectures."

TIME AND PLACE FACTORS IN NEUROLOGY AND PSYCHIATRY IN THE CLINICAL YEARS IN EIGHTY-FIVE MEDICAL SCHOOLS IN THE UNITED STATES

Class	No. of Schools in Each Class and Subject Divisions					Total No. Schools Teaching Neurology and Psychiatry in Separate Courses. Years and Average Hours.													Average Total Hours in N. and P. in Each Class in Clinical Years	Remarks

Tot.	85	54	42	25	5	55	32	..	47	..	27	...	2	.	42	..	2	..	..	

In order to determine what is actually being done in teaching neurology and psychiatry in the clinical years a study was made of the curriculums as disclosed in 1913-14 catalogs of 22 A plus, 32 A, 18 B and 13 C, a total of 85 medical schools in the United States, this number having responded to requests for catalogs. The results of this study bearing on the factors of time and place are shown in the table.

A consideration of the "standard curriculum" shows defects, first, in the preponderance of both time and place in neurology over psychiatry; second, in that no instruction whatever in psychiatry is given in the third year, and third, that both subjects are taught mainly in the fourth year. The same general defects are apparent in the curriculums of most medical schools as is shown in the tabulation.

The tabulation shows specific defects in the following particulars: first, that 5 out of 85 schools give no instruction whatever in either neurology or psychiatry; second, that as far as can be determined from the catalogs, neurology and psychiatry are combined in instruction under the collective terms "nervous and mental diseases" in 25 of the 80 remaining schools; third, that of the 55 schools teaching neurology and psychiatry in separate courses in both third and fourth years, 27, that is, less than half, give a place to neurology and only 2 to psychiatry; fourth, that whereas in these 55 schools 32 teach neurology, only 2 teach psychiatry in the third year; yet in the fourth year 47 teach neurology and 42 teach psychiatry; fifth, that the average total hours allotted to the department of nervous and mental diseases in the schools of each class is much less than the total hours recommended in the standard curriculum.

Is the total time allotted by the standard curriculum sufficient for adequate instruction even though it were properly apportioned between the subjects? This question cannot be answered until after a trial of what seems to be a proper apportionment of time between the subjects and until the subjects are given a logical place in the curriculum. It seems, however, that the importance of instruction in neurology and psychiatry during the clinical years in the production of competent practitioners should entitle these branches to an amount of time in the curriculum equal at least to that devoted to the nervous system in the fundamental years, which is now approximately 10 per cent., or 200 hours.

CONCLUSIONS AND RECOMMENDATIONS

To the end that an adequate working knowledge of the nervous system in health and disease may come into the possession of a larger number of future graduates in medicine, the following would seem necessary:

1. A better appreciation should be had by medical educators generally of the relations of the nervous system in health and disease to the whole individual.
2. Medical educators should consider neurology and psychiatry as fundamental and not as highly specialized clinical branches.
3. The aim of the instructors in neurology and psychiatry should be to aid the student in the general recognition of disease as well as in the recognition of nervous and mental diseases.
4. Less time should be given to discussion of diseases of the nervous system and more to the practice of simplified yet accurate methods in the recognition of them—thus developing the student's self-activity, self-criticism and proficiency.
5. The principle of relative values should be given greater consideration by the instructors in the fundamental and clinical branches in order that the principle of correlation may be better utilized by the student.
6. More and better apportioned time and a logical place must be allotted to neurology and psychiatry in the curriculums of our medical schools.

Metropolitan Building.

ABSTRACT OF DISCUSSION

Dr. Charles H. Hughes, St. Louis: We are in the transition stage in medicine. We have reached a point at which the medical profession is beginning to recognize the value of psychiatry and neurology in general practice. We have become accustomed to locating disease in the different viscera or systems of the organism and from thence judging as to the condition of the patient. As physicians we should consider the mind and brain as well as the other organs, we should consider the patient himself. Neglect of consideration of the patient has built up a lot of "isms" and "pathies" which by proper methods might have been avoided. Neurology and psychiatry in general practice have until recently been much overlooked in general medicine.

Dr. George Dock, St. Louis: Dr. Graves has made clear most and perhaps all of the important points necessary. I am particularly struck by the fact that people still look on the curriculum recommended by the American Medical Association as a standard, but from Dr. Graves' analysis it would appear that, as regards neurology and psychiatry, the medical schools in the country have not caught up with our standard. That perhaps is not the most important difficulty at present. With regard to the time, I differ from Dr. Graves only in the way of stating the matter. The standard curriculum gave two hundred hours, including the time given to formal courses in neurology and psychiatry, and also to practical work in the wards and outpatient department. It is a great disappointment to us who drew up the curriculum that more of that practical work is not done.

The most important part of Dr. Graves' argument is the emphasis laid on the development of technic. The desirability of this is not sufficiently realized in any branch. Neurology and psychiatry are not alone suffering from certain weaknesses in the method of teaching. Dr. Graves is disappointed because the medical undergraduate is not able to conclude his sensory tests or to recognize pupillary and sensibility changes, etc., as he should. We in medicine find men at the end of the fourth year who cannot positively determine albumin in the urine, or find tubercle bacilli in sputum, although they are easily found, and who are not sure of what they find by percussion and auscultation. We who have been long in the mill realize that the trouble depends on our still faulty method. These boys have not had enough technical training and not enough time in which to work in ward and outpatient department

The student may be taught to test sensibility, pupillary reactions, etc., but unless he works at a lot of concrete examples, as Dr. Graves emphasizes, he does not realize how critically he must work; how much more difficult it is, in the clinic, to detect albumin in the urine or sensibility changes, simply because he has not had the lesson. How will the student profit from a hospital year unless he has been taught to work most critically and unless he has more adequate oversight? We do not sufficiently consider the point that Dr. Graves emphasizes—the need of more and better trained teachers. Perhaps not so many young men are willing to go into neurologic work as in other lines, but the fault is not altogether with the lack of young men. The student goes into a clinic and works as best he knows how; but he has nobody over him to point out that his method of investigating the history or of making clinical and laboratory tests is wrong, and to see that he gets proper training. Everybody who has given the subject thought realizes that the need in every branch of teaching is more actual work with patients, with more oversight by a keen, well educated and specially trained teacher in charge.

Dr. E. E. Southard, Boston: From my experience in teaching neuropathology in the Harvard Medical School, I think one of the most important things in teaching the subject of nervous and mental diseases is to keep the student's mind busy during his whole course with something or other of neurologic interest. The injections of neurologic knowledge should be "spaced injections" during the whole course, with something put in every few months; otherwise the student comes to regard the subject as a matter of no importance. This idea—of neurology as a luxury—is entertained by many internists, and the adequate presentation of these topics may be measured by the degree of interest the internists take. If the internists connected with the school are narrow-minded, neurology and psychiatry will never maintain their proper place either quantitatively or qualitatively. One of the great difficulties in the American system has been that neurology has been regarded as somehow foreign to internal medicine. In Germany and England the neurologist is an internist, and, if called on to diagnose pain incidentally, he at least knows whether it is a case of rheumatism or stomach trouble. American neurologists are rather proud of their ignorance of internal medicine. On the other hand, the American internists are often proud of their ignorance of nervous and mental diseases. This is also true of pathologists. The pathologists that I know have a blind spot for the nervous system, while the same degree of detail in the kidney will arouse a singular tremor of autonomic vibration in them. They do not care to learn the somewhat complicated alphabet of our subject. The nervous system can secure proper attention in medical schools when there is a corporate spirit. One method is through "correlation committees" dealing with cognate topics as they are taught in successive years in the schools.

The only point I could add to Dr. Graves' discussion of the subject deals with the courses that lie prior to the courses of neurology and psychiatry. An elaborate course of neuropathology may not, in all cases, be secured in the second year; but the pathologists may be stimulated to take more pride in a neglected branch of their subject. There are many pathologists whose neurologic lore hardly goes beyond the diagnosis of a tabetic spinal cord, yet they know and teach about the Kupffer cells of the liver. If the course in mental and nervous diseases can be preceded with pathology in a sense broad enough to include neuropathology and a broad-minded internist is beside the neurologist, then I think you may get action. The work being done in connection with lumbar puncture is transforming neurologists, and to some extent psychiatrists, into internists and I predict that within two decades neurology, so-called, will have disappeared, because the internists will have learned about it, and, finding it somewhat simple, they will adopt it. I think that psychiatry will increase in importance because it will take many more decades for internists to get the social point of view. When consideration of the individual in his relation to society obtains, psychiatry will disappear, because everybody will be a psychiatrist.

Dr. C. R. Woodson, St. Joseph, Mo.: Dr. Graves did not intimate that it was necessary that all who studied psychiatry or neurology should be finished psychiatrists or neurologists, but that it is important that the present-day graduate should know enough about nervous and mental diseases either to give himself, or to diagnose that somebody else may give, timely treatment. A routine treatment of unconsciousness, whether the result of a cerebral hemorrhage, an embolism or a thrombosis, is too common with the general practitioner. To recognize this trouble and to determine its cause is important, not only to the medical profession, but also to the individual. The recognition of mental disease while on the border line is the important thing. The individual who is told that he has appendicitis or gall-bladder trouble, or some other condition demanding surgical skill of the highest character is hustled to the hospital. The individual, however, who has loaded his carrying capacity beyond a healthful resistance, whose condition is the result of concentration of thought or overattention to business, and who is in danger of losing his mind, who is made up of hesitation and doubt, whose mind dwells on himself, who tells the physician he consults that he thinks of taking his life, is in a condition that should be recognized. And until the physician is sufficiently trained to appreciate the fact that this is important, that this patient does not have the power to decide, is devoid of initiative and that the family as a rule does not want to decide for him, these mistakes in practice will continue. While, in such a case, they hesitate and conclude to leave to the patient that which he has not the power to decide for himself, they will hustle the surgical case to the hospital; but the mind of this patient is as necessary as the kidney, the gall-bladder, an arm or a leg. The thing to do is to get him to some place where he can be treated or where they know how to treat him while he is still curable. There is a disposition on the part of many in the medical profession to treat paralysis with strychnin; but in a hemorrhage of the brain inject strychnin, and what will happen? The diagnosis is the important thing. It may be said equally truly of other branches of the profession that students do not come out in four years, capable; but they ought to come out with sufficient ability and knowledge to diagnose a case.

Dr. Walter B. Swift, Boston: I have met the problem of methods of instruction in nervous diseases. When I was made instructor in neuropathology in the Tufts Medical School, I found the students brought very little from courses below which they could use in my course. And the courses below were not to blame. One trouble was this lapse of time of which Dr. Southard speaks. I can add that with charts, lectures and diagrams the students carried little to the courses above mine. I met this problem with success by the introduction of two ideas, repetition and visualization. By repetition I mean this: I repeated in my course all the essential data they should have brought up from other courses, anatomy, histology, pathology. Of four months put on the course, three were spent in review before ever mentioning the new and finer parts of neuropathology. Then one month on that subject. Visualization, however, is the secret of making neuropathology easy. Dispense with all charts, diagrams, didactic lectures preceding demonstration, and first show the tissues; get this well pictured in the mind and afterward dilate in words, but only to enhance that visual picture.

Dr. Charles R. Ball, St. Paul: Formerly mental and nervous diseases to the ordinary medical man were not very attractive. I think now, however, we all realize that conditions have changed. The neurologists have illuminated the subject so well that both surgeons and internists are beginning to look in our direction. We should regard this as distinctly complimentary. Since the excellent work which we have done on the subject of nervous syphilis, syphilographers have united with the internists and show a desire, also, to enter this field. As yet, however, the subject of psychiatry does not appear to be so much encroached on. With regard to medical education, the greatest fault that can be laid against it is the failure thus far to teach students to recognize and treat in an intelligent manner functional nervous diseases. In our method of dealing with this class of patients more reproach has undoubtedly been brought on our profession than in any other class of cases. I hope Dr. Graves' paper may give the impulse to decided reforms in the teaching of neurology and psychiatry in medical schools.

Dr. Hugh T. Patrick, Chicago: In my opinion this lack of interest in neurology and psychiatry and the feeling of inadequacy on the part of the graduate is due to the enormous amount of malpractice which has taken place in the chairs of these departments. I know of no other chairs in medical schools which have maintained as much abuse as have the chairs of nervous and mental diseases. When the subjects of neurology and psychiatry are adequately and properly presented to a medical class, the members evince as keen an interest as they do in any other subject. In present-day medical classes there is a beautiful keenness and anxiety to learn and to acquire a knowledge of the nervous system and its diseases. And I believe that any lack of attention is due to the man in the chair. Therefore the criticism that I would make against medical schools is that they have not always picked out the man who is able properly to instruct and to hold the attention of the medical students, but have selected a teacher for reasons of expediency. Or a man is sometimes given a chair not because he imparts knowledge well, but because he is eminent in his department. That is entirely the wrong basis for putting a man into the work of teaching. He may be head of the department, but he should not be given work for which he is not amply fitted.

Concerning Dr. Southard's remarks, in the school with which I am connected we have tried to carry on this continuity. In the second year the students have a course on physiology of the nervous system given by a member of the clinical staff; in the third year they have a text-book and recitation course, the aim being to give them a clear conception of nervous diseases. That prepares them for the clinical work in the fourth year. And the thing that I think is of most importance in all these things is not to try to teach too much. The teaching is inadequate, as Dr. Graves has said, but, in my opinion, it is because an effort is made to teach too much. For instance, the teacher himself is interested in some of the refinements of nervous diseases, and he, naturally, teaches what he is interested in. That is a matter of self-indulgence. A teacher must adjust himself to the man on the bench: What can the boy hold in addition to what all the other departments teach? In the next place, give him the fundamentals, the real things he must know. When a teacher of neurology gives his students twenty symptoms of tabes, he is guilty of malpractice. There are only a half dozen symptoms the boy ought to know, but those he must know absolutely; but loaded with too much, he does not know what are the essentials and what are the superfluities and refinements.

Dr. William W. Graves, St. Louis: The burden of my complaint is that because instruction in neurology and psychiatry is put off until the fourth year in many medical schools in this country, the student does not have a chance to learn that it is necessary to consider the nervous system and its reactions in the recognition of health and disease. This is, of course, a serious defect in medical education. To remedy this defect neurology and psychiatry must be given logical place in the curriculum; that is, from the beginning to the end of the clinical years and the subjects must be given adequate time, that is, one hundred and fifty hours at least during the clinical years.

PRESENT-DAY PUBLIC HEALTH ACTIVITIES *

FRANCIS E. FRONCZAK, A.M., M.D.
Health Commissioner
BUFFALO

Perhaps in no other field of scientific progress is the axiom that "the luxuries of yesterday are the necessities of to-day" more true than in that of public health.

Let us apply this to the laboratory alone and we will have the verification. What was formerly scorned as indicative of ignorance is now used as a matter of necessity.

So various have become the branches of the many activities in public health work that their mere enumeration with but slight comments would occupy the scope of this paper. I will devote brief attention only to those in the limelight.

Complaint is frequent, and sometimes justly, that there is too much paternalism, that too many persons exist at the expense of the public and that the number who slip through life from birth to death without worry as to who pays the bills is constantly increasing. Legislation and private philanthropy combine to assist. While they do not give the comforts they at least provide the necessities.

In many cities, and this is especially so in Buffalo, there is a close cooperation between the Department of Health, Police and Education, and the various private philanthropies. While formerly it was considered proper to tell your troubles to the police, it is now essential to transfer them to the Department of Health. Such messages by mail and telephone are so rapidly increasing that with us it has become a part of our regular work.

Some of the work formerly done by the police has been transferred to the Department of Health, notably that of caring for the insane. Forcible restraint has been replaced by medical care.

Permit me to enumerate some of the most important activities.

VITAL STATISTICS

For many years this country has been too busily occupied with what was considered more important matters, and for that reason many details had to be neglected. As the country grows older it learns much by experience. Many of our customs and laws are the result both of experience and evolution. Vital statistics is one of these. No great importance was attached to this subject; births and deaths were considered as part of the laws of nature. It was not even considered unusual that pedigreed animals should be registered and accurate records kept. This was a question of commerce and justified on that ground, but when it came to vital statistics, the making of a record of every child born, and a record of every human being who died, it was considered red tape. Experience gradually showed that this was not red tape, or the effervesence of some officious mind, but an actual necessity. As this feeling gradually grew on the public they began to comply, and in the greater part of this Union it is an obligation, not only recognized but made mandatory by law.

The question as to how this can best be accomplished is a debatable one, and the answer to this must also rest to a great extent on experience. It has been shown that so long as the registration of births and deaths is left discretionary, just so long they will be incomplete. Incomplete records are worse, at least for statistical purposes, than none at all. It is a public delusion. The public believe where a registration is in force that all vital statistics are recorded. Where it is discretionary perhaps the very records that are sought will not be found. Therefore, the only way to ever obtain correct records is to make registration mandatory and to provide an adequate penalty for neglect. This was the contention which we, in Buffalo, made for the past twenty-four years, and under which we succeeded in getting perfect records of deaths and almost perfect records of births. For many years other communities disputed this point with Buffalo and said that it savored too much of European autocracy.

It is a pleasure, however, and a justification of Buffalo's course to note that the model vital statistics law, which has been adopted by the state of New York and certain other states, is based on this theory as being the only one by which accurate vital statistics can ever be obtained.

ISOLATION AND CONTROL OF COMMUNICABLE DISEASES

Nothing in public health activities has made greater progress and nothing has undergone greater evolution than is shown in the question of communicable diseases. Those of you who have been in public health work for the past twenty years or more will agree with me that there is no comparison between the methods employed then and now. While even at that time epidemics were no longer looked on as the visitation of Providence, yet some of the methods in use were still remnants of the same theory. In no other line of public health work has science played a more important part. With the aid of the laboratory, we have learned the cause of most diseases, and with this knowledge came the result in methods. We no longer quarantine diphtheria for an arbitrary period, but only so long as the germ manifests itself. As in diphtheria

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

so in other communicable diseases, our knowledge has spread and gradually our methods have changed.

COMMUNICABLE DISEASE HOSPITALS

Hospitals for communicable diseases are more and more coming into general use. I do not care to discuss this subject at any great length except to express the belief that they will be a great factor in the control of the diseases mentioned.

HOSPITAL SOCIAL SERVICE

Among the great changes in hospital work, none is more important than recognition of the vicious relationship between poverty and disease. Many maladies are dependent on the attributes of poverty, insufficient food, want, bad housing, etc. Remedying the disease and returning the individual to the same condition is a labor lost, and thé method of following cases to their environment and bettering conditions there is a movement in a direction that is corrective in a true sense of the word, and will be productive of results in the highest sense of the word.

TUBERCULOSIS

It is a sad commentary on the many and great activities both by public health authorities and by many private philanthropists throughout this country, that in spite of their varied activities hardly any impression is made on pulmonary tuberculosis. This statement may be disputed by some. With the amount of energy concentrated in this one direction it would seem that a corresponding amount of results ought to be accomplished. During the past few years many societies have organized to assist their respective localities in exterminating this disease. Public sentiment has been worked up to a degree never before witnessed. With the cooperation of the public, everything that the human mind and medical science can advise is being done. Consumption has been made a reportable disease. Its victims are looked after, instructed, provided for, isolated, segregated, and the public in general has been carefully instructed as to all the questions involved. Hospitals and sanatoriums have sprung up almost like magic in city and country for the exclusive treatment of this disease.

And yet in spite of all this we stand aghast and note with consternation the fact that consumption claims as many, and sometimes it seems even more, victims than it did before.

Here is a subject for reflection. Here is food for thought. I will not attempt to enter into a discussion as to the reason why. I leave it for you. For you, who represent every section of this great country, to take this thought home with you to look over the situation as it pertains to your own locality to compare with that of others and if possible to offer a solution. I can state, however, that I can almost see that the next generation will surely reap the benefits of this constant warfare on the white plague. So let us keep at it unflinchingly.

CLEAN-UP WEEK

The yearly municipal clean-up week, a distinctive American innovation, is an activity that has come to stay.

In addition to its material benefits, its educational feature is not to be overlooked. For weeks, the press, with its characteristic liberality, heralds its approach, and sings a daily song of cleanliness and health that is not lost; the scholar brings home a lesson to the household with the moral weight of its source, and the Boy Scout, now an active and important participant, receives an education in civic duty that cannot but influence the man of to-morrow.

The experience of Buffalo is that the clean-up week is yearly growing more popular, and its beneficent results in proportion.

SWAT THE FLY

Stimulated by results obtained in making the Panama Canal region safe, the world awoke to the possibilities of exterminating the mosquito and fly. The results have been marvelous. The slogan "swat the fly" superseded that of "the fly that does not wipe its feet" — the former is shorter, but the latter more expressive. "The Fly That Does Not Wipe Its Feet" was the heading of an article printed in the *Bulletin* published by the Buffalo Department of Health in 1908. It was copied extensively from the Atlantic to the Pacific and in some European countries. There is no doubt as to its effect. The many fly campaigns waged everywhere are sufficient evidence. Permit me simply to emphasize one thought. I would suggest the selection of "catch the fly" to replace all others. In our experience the question of fly extermination depends chiefly on catching the flies and the best way of so doing is by fly traps set at places where flies mostly abound whether it be in the house, the barn, the manure heap, or the garbage pail. It is useless to swat the individual fly and let the million escape. It is also useless to inaugurate fly campaigns for the purpose of rewarding those who produce the greatest number of dead flies. There are many unscrupulous enough to create fly hatcheries for this special purpose in order to receive the remuneration.

Therefore "catch the fly," and catch him with a fly trap.

Aside from this, "prevention" has become the great goal of all public health activities. The old axiom about an ounce of prevention had a beautiful sound, but seldom with a tangible response. This has been replaced by the popular cry of "safety first," and by common consent public health authorities have been shouldered with the responsibility of general prevention. This summarizes the entire question of isolation and control of communicable diseases. It is not a question of education or publicity so much as a question of authority to act.

VENEREAL DISEASES

The treatment of venereal diseases has too long been left in the hands of charlatans and leeches who suck out the gold while they frighten their victims into a silence. Their victims are numbered by the thousands. Why this disease, which always has and always will exist, should be left in the hands of quacks and unscrupulous persons, rather than treated by reputable physicians or assisted by municipal authorities, is explainable only through the delicacy felt by the unfortunate victims. At one time patients suffering from cancer or tuberculosis considered the same privacy as essential, and in some places this condition is still met, but it is gradually fading. We can readily understand why a man or a woman, who either innocently or otherwise, has acquired a venereal disease, should shrink from permitting that fact to become public property. For the same reason they do not always consult their family physician whose counsel and help would be inestimable. In order to preserve their secret they usually consult advertising quacks and learn, when too late, that they have done the very thing they sought to avoid. The quack who can thrive only by fraud, deceit, and everything that is unscrupulous, throws out such alluring baits, both as to his guarantees to cure and his work without pay, that the victim allows him to proceed. It is soon found that these guarantees and promises must be met by the patient with the required amount of cash and the patient finds that this is but the beginning of a continuous blackmail. Is it any wonder that we have hereditary syphilis, that our asylums are becoming more and more crowded, and that our suicides increase?

In many parts of the country, health departments or private philanthropies, or both, have started reactionary measures, such as making venereal diseases reportable like other communicable diseases, making free examinations for gonorrhea and syphilis, providing hospital care for those in need, and what will perhaps be the most efficient of all, the inauguration of a system by which the influence of the venereal quack is minimized. This is done by a systematic meeting of the quack's methods. Public water closets, which are plastered with venereal advertisements, are decorated with warning cards. Public advertisements in the press are offset by other advertisements issued for the purpose of calling attention to the impossibilities of fraudulent advertisements, the impossibility of curing as guaranteed, and the impossibility of any person existing and continuing to do business under heavy expense without proper remuneration, and, therefore, the impossibility of treatment without pay, and finally advising such unfortunates what to do. All these methods are valuable. Each has its advocate, and each must leave an impression.

From many years of observation I maintain that nothing will be accomplished until authority is vested where it belongs, namely, in public health departments. My first plan would be to make it impossible for any person to practice a medical fraud. It would seem that there is already sufficient law covering this point, but it is difficult to enforce. The influence of the quacks, through the millions which they spend in advertising is so great as to render it extremely difficult to put them out of business. In Buffalo we have succeeded in abolishing a few of the worst ones by merely obtaining a fraud order from the Postoffice Department by which it was impossible for the quack to receive mail, and which also made it impossible for the papers containing his advertisement to be mailed. Under this procedure alone it seems to me that the entire army of quacks could be wiped off the map. No community will tolerate another person who advertises deceit and fraud, and why the medical quack should be given preference is difficult for the ordinary person to comprehend. Not only this, but it is an insult to the common decency of every community.

MEDICAL SCHOOL INSPECTION

Although this is one of the newer methods employed in various cities, yet its popularity has been so immediate that every town or city of any pretention whatever has some form of medical school inspection, especially in the state of New York, where it has been made compulsory by state law. The Fourth International Congress on School Hygiene, held in Buffalo in 1913, and whose proceedings have just been issued from the press, has greatly advanced this public health activity. It is therefore unnecessary to enter into this subject at length, but merely to say not only that much has been accomplished, but also that it is difficult to see how we were able to get along without it. Medical school examiners, school nurses, dental inspectors, dental dispensaries, eye, ear and throat infirmaries, are now all looked on as necessary adjuncts of school life. The question has been raised as to whether medical school inspection properly belongs to the health or school authorities. In Buffalo we have formed a combination of the two and consider this the best solution.

Open air schools have likewise swept the country, but as far as I know Buffalo again has the distinction of having the first school in which tuberculous children are treated, and at the same time educated. If there be any class of children whose minds should be cultivated while their bodies are treated, it is the tuberculous. Physically handicapped, it will be necessary for them in adult life to depend more on their mental abilities, and for this reason, if for none other, their mental requirements should be attended to at the same time that their bodies are made well.

THE SUBNORMAL CHILD

The segregation of mental defectives, better called the subnormal children, is another great question worthy of more attention than has thus far been given to it. As a rule when these unfortunates become too old to attend special classes they are turned loose into the world to become criminals. Suitable provision should be made whereby they can be restrained and cared for until they become self-sustaining.

Does medical school inspection and school nursing deprive the regular practitioner of his legitimate work? At first glance it would seem so, but in Buffalo the opposite holds true. In the course of a year's inspection thousands of pupils are discovered with various physical conditions or diseases requiring treatment. These are all sent to the family physicians, instead of being cared for by the medical school inspectors. Most of them would have escaped for years, perhaps forever, to their own detriment, and to the loss of others; and instead of remaining a community liability became valuable community assets.

CLOSING SCHOOLS IN EPIDEMICS

With our present knowledge of treating communicable diseases it seems strange that many physicians of experience should still hold to the obsolete theories of checking an epidemic by closing the schools. In my mind there is not a single justification for such an act. We have many schools in our city containing from one thousand to three thousand pupils each. Take one of the latter for instance: If we had one hundred cases of any one infectious disease in it, why should 2,900 pupils, who are not ill, be deprived of their privilege? As an illustration let me tell you of an epidemic of diphtheria which occurred in one of our largest schools last fall. Case after case was reported within a comparatively short time, and the medical school inspectors were instructed to locate the source. Every child showing any symptoms of coryza or any clinical evidence of diphtheria was culturized, and, if the culture was positive, excluded. Still new cases cropped up daily, and as a result every person in the school, from the principal to the janitor, was culturized. In that way a number of diphtheria carriers were found and excluded. This broke up the epidemic at once. Had the school been closed the carriers would have remained at large undetected and would have continued to spread their disease. What holds good in diphtheria is also applicable to other diseases.

FREE PUBLIC BATHS

Buffalo has the distinction, as well as the honor, of being the first city in the world to establish and maintain absolutely free public baths. Several so-called "free baths" existed prior to ours, but inasmuch as they charged a penny for soap and towel, they could not be considered free, even if the charges were only nominal. We have two such baths situated in different parts of the city, in buildings erected especially for this purpose, with separate quarters for males and females, and each bathing establishment also containing a laundry where the bathers may wash their garments, place them in a steam dryer, and find them ready for wear by the time they are through with their bath. That these free baths and laundries are appreciated is shown by the fact that over 300,000 men, women and children make use of the baths annually, and over 10,000 make use of the laundries.

The city of Buffalo considers this a splendid investment. Only shower baths are used, there being no plunge. By standing under a shower there is no possible chance for personal contamination, and each bather is given a piece of soap and a clean towel on entering, which they are again required to deposit on leaving. Prior to that time we had free bathing on the beaches of the lake and river, which was limited to the short period of summer. For those who could afford it we had public bathing establishments and private clubs. Within recent years, however, a number of our public schools have had swimming pools and bathing facilities added, which are likewise free; but in spite of all this the popularity of our free public baths continues.

EDUCATION IN PUBLIC HEALTH

This subject ought to be added to the curriculum of every medical college. Workers in public health appreciate this. Many a student receives his degree of Doctor of Medicine who cannot even make out an acceptable birth or death certificate. The Buffalo Department of Health has offered the medical department of the University of Buffalo all the facilities at its command, whereby the students are given opportunity to study the methods of our department in all its phases, from the conduct of the general office to the inspection of schools, tenements, etc. Every medical student is now obliged to take this course, which is bound to bring most excellent results, and be of great value especially to those who in the future will become health officers in the various localities where they may practice after graduation.

LABORATORIES

Preventive medicine, serum therapy and laboratory findings are rapidly displacing the healing art and is giving way to the preventive art, and individuals are treated as much as their ailments.

In this connection no factor plays so important a part as the laboratory, and no practitioner can do justice to the responsibilities in the absence of its aid and resources.

All organized departments maintain a bacterial and chemical laboratory in the interests of the public health and available to the profession where located.

So important are its functions that they are made available to nearby communities who are not able to maintain so expensive an equipment.

In addition to its use in medicine, such equipment, especially the chemical division, is made use of largely in commercial lines. Much money may be saved by subjecting materials to analysis to determine their character, fitness and compliance with specifications; cement, rubber, paint, oil, coal, gas and various other commodities can be subjected to tests under such circumstances. The school, public works, and fire and water departments avail themselves of the facilities and the methods adopted by our large industries can be utilized to the best advantage.

ANTITYPHOID VACCINATION

One cannot refer to bacterial work in relation to public health without having in mind the use of the typhoid bacterin administration, its high value and efficiency; this is before the country at this time.

At present our army is and has been assembled for months under the same conditions that obtained during the Spanish-American War, when there were about twenty thousand cases of typhoid and about fifteen hundred deaths. On the frontier and in Mexico since the troops have been gathered, there have been practically none (one or two, I believe, at the utmost) all due to enforcement of the antityphoid vaccination order.

It is accepted that typhoid is contracted in many other ways than by water, through contamination of farm products, milk, etc., and inasmuch as control over this etiologic factor is not as yet as it may be, it appears indicated without question that its administration should be urged, much as with vaccination in small-pox. Buffalo's health department for the past two years has been administering free antityphoid bacterin to all applicants, especially urging it to the physicians, nurses, commercial travelers and all those who spend their vacations in the country, or where the water supply is not beyond suspicion.

SANITARY CONTROL OF FACTORIES AND INDUSTRIES

Many factories and industrial establishments are conducted more or less in an avoidable insanitary manner.

Among causes determining this are the absence of ordinances with specific requirements, indifference of owners in allowing sufficient time for the purpose of cleaning, poor adaptation of buildings, indifference to consequences, and the custom of adapting ordinances to conditions instead of conditions to comply with ordinances.

Many advances, however, have been made, ingenious devices and appliances offset unhealthy occupations, poorly ventilated and lighted factories are growing less, dressing room and other facilities are being supplied, while many of the large representative places are ideal in their equipment.

The operations of the new New York State labor law are bringing about advantageous changes in all these matters.

Conditions in the retail food industry, however, are a fertile field for activity, particularly in the closely congested sections with recent arrivals to this country, and in the case of small places. Fly and dust protection and improper association for foods is most difficult to secure, by reason of ignorance, and the want of appreciation of the significance, especially as the enemy (germs) is an invisible foe and the distinctions in cleanliness do not appeal.

MILK

While the protection of foodstuffs is one of the foremost works of the day, the activities in milk work are distinctive.

Its importance as a food, its peculiar characteristics and susceptibility to contamination, its intimate association with infant mortality and with tuberculosis, render the duties of conserving it one of great importance and responsibility. It justly occupies a foremost place in the activities of all highly equipped departments. Its consideration here must of necessity be brief, and will be limited to a reference to Buffalo's activities the past few years, and some thoughts in connection therewith.

Six years ago Buffalo was supplied by about two thousand uninspected dairy farms in all sorts of conditions; it was brought to the city under unprotected transportation, distributed by about three hundred dealers, and for reasons beyond control at the time was without systematic inspection, and much of the milk was characterized by a bacterial count in the millions with colon, and much of it unfit.

The work by my direction was placed under the supervision of W. H. Heath, a former officer of the Public Health Service, and now chief of the Bureau of Food and Drugs, with instructions to systematize it with safeguarding requirements and get results.

The changes were radical. The inspecting corps was increased, a dairy farm inspection service established, a standard for production and for admission adopted, which included a bacterial limit of five hundred thousand and no colon, and ordinances were enforced.

As a consequence of rigid enforcement and administration the findings to-day are that it is produced by but fourteen hundred dairy farms (600 being discontinued) under routine inspection, distributed by but 250 dealers under routine inspection and living up to ordinance requirements.

The milk is examined as it comes from the producer and compared with findings as delivered to the consumer, and discrepancies as to character and contamination are acted on in accordance. As high as 95 per cent. comes in under requirements for admission. Poor milk is the rare exception. Fewer activities are characterized by a more satisfactory evolution from the detrimental to the desirable.

Within but a few years milk inspection was from a commercial point of view, and the influencing factor with the public was the cream line. All milk looked alike, and the important matter of its contamination and possibilities were unknown and unconsidered. Through department activity and dissemination of knowledge through the press, settlement workers and other factors, a different attitude is in evidence, and there has been a general awakening on the part of the householder in regard to milk notwithstanding which, however, there is not, as yet, that sympathetic interest which should obtain.

It has been said that a community can obtain as safe a milk as there is demand for and money to pay with, but this can come only through enlightenment, and an appreciation of the conditions. To that end, therefore, as public health is largely a purchasable commodity, a department should advertise, make use of the daily press and talk to the entire community. Provision should be made for space and at stated intervals pertinent information on health matters and guiding information on foodstuffs and the industries should be made public. Advantage should also be taken of other methods of getting to the public, and street-car advertising, by methods that appeal to the eye, are suggested.

THE MILK BOTTLE AN EDUCATOR

It has also occurred that the milk bottle could be made use of; that it could have a mission and carry a message in its daily entrance to the household. It could carry a label or tag furnished the distributor by the department, with brief epigrammatic information how to care for milk, what to do when the baby is sick, the danger from flies and the like. In other words, make the milk bottle an educator as well as a carrier. The message day by day could not but awaken interest and make an impression.

The value of inspection is largely educational, and to that end, an inspector must have the knowledge and be able to convey it to others. A department should conduct, to my mind, a system of instruction for its inspectors, that they can cover this phase of the situation with efficiency. Such action is now in vogue at the present time in the department over which I am in charge.

LICENSING AND EXAMINATION OF MILK DEALERS

In this connection other thoughts have occurred to me. No industry has greater potentialities for detrimental consequences than the milk industry. The careless or ignorant druggist may poison one or two; the plumber through defective work cause sickness of the family; the butcher prostrate a single household through bad meat, but the ignorant or careless milk dealer may, before he can stop, carry infection and sickness to every home on his route.

If the law demands plumbers to be licensed, a drug clerk and even a barber to be licensed and to determine fitness in protection of the public interests, is it not much more important to license a milk dealer?

It is believed that no man should be eligible for a permit to engage in the milk business unless he holds a license to be a milk dealer and engage in such business. A certifying board similar to the board that certifies to the fitness of plumbers should pass on the fitness of those who desire to handle this important commodity. Applicants should at least have a rudimentary knowledge of the relation of milk to sickness, of its possibilities in its relation to the public health, elementary knowledge of what is meant by contagion, the A B C of sanitation, the reasons for cleanliness.

This will eliminate the ignorant and often stupid individual who, at the present time, with the command of a few hundred dollars, may engage in peddling a few cans of milk, and who may be more or less of a constant menace. Such certifying board might be composed of a representative milk dealer, a member of the health department and an outside business man, and could be appointed by the county judge.

PASTEURIZATION OF MILK

When it is considered that a proportion of the milk herds are tuberculous, and that the disease is transmissible, especially in the case of children, a problem is presented that is as cogent as important. As elimination of the infected cow is not feasible from an economic standpoint, and as pasteurization is practicable and efficient, the question of pasteurization of the city's milk is one of the indications of to-day, and should be adopted by every community.

In view of all the circumstances attendant on such procedure, an important proposition is as to whether a city of moderate size should not maintain a pasteurizing plant in the interests of the public welfare.

The subject is beyond the scope of this paper, but for some time it has been in my mind that the principal contaminating utensil, the milk can, should be sterilized under municipal control, and such action is under contemplation.

If there were a municipal sterilizing and pasteurizing plant available to the industry, it would go far toward eliminating some of the most serious of the detrimental possibilities.

It is my intention at an early day to bring this matter before your attention, as I believe it would justify your consideration.

REGULAR SOURCE OF PUBLICITY

Nothing adds more to the value of public service than publicity. It can seldom be overdone. The public has a right to know not only what the law requires, but also what the health department does. I have often noted the serious results obtained through concealment. The public has a right to know that an epidemic exists just the same as it has a right to be proud of the fact that the community is free from disease. In my department I have employed three principal methods—a regular monthly bulletin published by the department containing twelve pages and having a circulation of ten thousand with each issue. I have found this bulletin sufficiently large to give in a condensed form the activities of the various bureaus of the department, as well as giving much information pertaining to public health which I know the public appreciates. These bulletins are issued free and mailed to the physicians, dentists, undertakers, midwives, clergymen, school principals and teachers residing in the city of Buffalo, and to other residents who apply for it.

All information contained in a department publication should be authentic, should be up-to-date, and should be edited by some person familiar with public health work, having the confidence of the medical profession and considered authority on such matters. In this way only can the confidence of the public be reached and maintained.

The other method which I have adopted and found to be of great value is to disseminate information through the daily press. In a large city so much occurs continuously that it would be impossible to wait for the issue of its monthly bulletin, much less to crowd in all that should go. The daily press therefore becomes a necessary adjunct. Like other news the health department information thus reaches the public while it is yet news, and is therefore of greater value. The influence of the daily press is also a matter of common knowledge, and this influence is a necessary adjunct for any public health department.

The third method is the distribution of small hand circulars of the most concise nature. These are printed in the several languages most commonly used in the municipality.

I am not much of a believer in voluminous medical articles in weekly or monthly magazines. These contributors often write against space, at so much per line, with a corresponding loss of the value of their production.

INFANT MORTALITY

Not so many years ago infant mortality and "the survival of the fittest" were always associated in the minds of the public. Parents took it for granted that a certain number of children were born to die in infancy. As civilization advanced, the number of births gradually reduced, but the number of deaths was not reduced in the same ratio. Then it was that the question of infant mortality received such consideration that every feature entering into the cause was carefully investigated. It was found that this was not an ordinary result of natural conditions but a simple question of cause and effect. Efforts were then started toward preventing the cause, and the effect is becoming apparent everywhere. The percentage of deaths in every well-organized community is annually growing smaller. Wherever this is not the case it indicates carelessness or inactivity. Most of you can recall the time when long tube nursing bottles were common in every household when milk was permitted to remain at the most convenient place; when flies were if not a welcome at least a necessary adjunct; when garbage and filth were thrown out of the nearest store or window and permitted to accumulate; when no attention was paid to food and drink; when nobody ever thought of investigating dairies or examining cows; when milk was milk and that was all there was to it.

I might continue to multiply this list, but my only object is to show what was and to call your attention to its elimination. We may summarize it all by "cause and effect."

While education played an important part in these results, I am afraid that it gets more credit than it deserves. When you ask this question, I am sure your answer will be the same for your locality as it was for mine—that while education and publicity play important parts, the chief credit is due to adequate laws by which the health departments are enabled to back up their demands in an efficient manner. People are the same the world over. As much as they may agree to the justness of your request the majority will never comply unless your request becomes a demand and that demand can be properly enforced by law.

This is what has made the great impression on infant mortality and has reduced it from what, years ago, was a blot on the country and a criminal insult to our intelligence to a state which, while yet far from ideal, can at least be called satisfactory.

FUTURE ACTIVITIES

Now that the reduction of infant mortality has been properly looked after, let us devote some attention toward the reduction of adult mortality. Far too many die during the best years of their lives from organic diseases. Their activities are cut short at a time when their services, or at least their experience, is worth the most. However, this subject is so great and so important that to enter into it properly would again carry me beyond my time allowance. Let me only say that I consider this one of the greatest of future activities in public health work. I believe that we ought to reduce the various organic troubles of adult life as we have reduced the causes of infant mortality.

In thanking you for your attention, I beg your indulgence. The responsibilities of a department with widening sphere of action, the many claims on time incident thereto, have necessitated the hurried preparation of these remarks, at a time usually devoted to sleep and rest. If, however, they will awaken some interest and elicit discussion, their purpose will be more than fulfilled.

Municipal Building.

ABSTRACT OF DISCUSSION

Dr. W. A. Evans, Chicago: I know of no separate statistics in this country that are in greater need of standardization than the baby death-rate. It is so easy to show the cause of death of babies under 1 year of age, that some years ago I accepted the conclusion that, in considering the infant death-rate we must totally disregard the cause of death as given on the death certificate—it was so thoroughly undependable. The question then arises how we shall estimate the death-rate of babies living less than a year. In view of the faulty birth registration in most of our communities, probably the most accurate method is to estimate the death-rate on the basis of population under 1 year of age. It would be difficult for me to conceive so rapid a drop in death-rate; and I must believe that a good part of it is due to the fact that the attention drawn to it served to change in the direction of greater accuracy the cause of death as it appeared on the death certificate. When I went into the department of health in the city of Chicago, one of the things needing serious attention was what should be done about the baby death-rate. Men who were engaged in caring for babies told me that, in their judgment, the evidence from a clinical point of view did not indicate that infantile diarrhea was to be handled as a bacterial disease. We know that, from the point of view of bacteriology, proving a bacterial cause for infantile diarrheas has met with indifferent success. As the result of our investigation the situation developed to include milk (which came under the auspices of the health department), and nursing (which is, in the main, extragovernmental). Our death-rate has not improved, though the milk-supply has.

Dr. J. W. Trask, Washington, D. C.: What Dr. Evans says with regard to the method of calculating mortality rates is all too true, especially for this country. Improved registration of births will give an apparently decreasing or falling infant mortality; and that applies to the whole country.

Dr. W. S. Rankin, Raleigh, N. C.: Dr. Evans has suggested that the fall from 134 to 92 deaths from diarrheal diseases of infants per hundred thousand population is due to greater accuracy of the physicians in making out the death certificates. The evidence bearing on this suggestion will be found in the relation of the drop in the special death-rate to changes in the general death-rate. If there is a similar decline in the general death-rate, the evidence is against Dr. Evan's suggested explanation; if, on the other hand, there has been a decline in the special death-rate without any similar decline in the general death-rate the evidence favors Dr. Evans' suggestion.

Dr. C. Am Ende, New York: I have been for several years in charge of the children's clinic and I have found that, usually, in the summer time the cases of diarrhea that come to me are largely affected by the incomplete sterilization of condensed milk; and when I explain to the mothers that they must boil the condensed milk, together with the water they use in its dilution the diarrheas stop promptly.

Dr. C. Hampson Jones, Baltimore: If we can get away from the idea of having any special day or special week for city cleaning, it will be better. In Baltimore we have been trying to do this for some time; and I think we are approaching success. A large number of the police force are in the day service, and constitute a moral rather than an active force in the control of violations of law. We have obtained the cooperation of the police commissioners in having the day policemen perform sanitary work in the direction of constant inspection of the yards, cellars and alleyways of properties on their respective beats, with power to enter whenever they choose to instruct the people what to do; and, if those instructions are not carried out, to invoke the law and to arrest. I don't know how successful it is going to prove; we believe that it will be excellent; and, finally, it will do away with the piling up of filth until the cleaning-up day.

Dr. Charles J. Hastings, Toronto, Ontario: I have always taken decided exception to this "clean-up day" or "clean-up week"; my idea is to make the clean-up process a continuous one. It is not possible to depend on the complaint system; because in the parts of the city that it was most needed the inhabitants were practically all in the same ship, and therefore were not going to complain of each other. Complaints usually come from the better districts of the city. Therefore, I had the city divided into (twenty, at present) sanitary districts, and one man held responsible for each district, and he patrols it regularly. In addition to that, we have the cooperation of the police officers of the city, who are required to make a note of any insanitary conditions they see, and are furnished with blanks on which they report to the department of health. While, as Dr. Fronczak says, there is an educative value in drawing the attention of the public generally as in a general spring house-cleaning, yet I feel that if we want to get our cities cleaned up and keep them clean, we must divide them into sanitary districts and have competent men in control over those districts.

Dr. Davis Furman, Greenville, S. C.: I live in a small town and have been connected with the health board there for some time. Quite recently we provided for a clean-up week. We have a pretty good corps of officers, whose duty it is to look around town and see that everything is clean; but the clean-up week brought to the surface tons and tons of hidden garbage; and it was evident that whitewash, soaps, varnish and disinfectants were freely used, even by the negroes. We made it a little more interesting by offering some premiums for the cleanest ward.

Dr. Francis E. Fronczak, Buffalo: The idea of having a clean-up week is not to have the city clean that particular week only. The purpose is to arouse in the ignorant and those who are, as a rule, slovenly and uncleanly, ambition to fall in line and do, during the clean-up, what others are doing the entire year. Clean-up week not only is a forcible reminder to the people that they should keep clean their houses and homes, but gives the idea of adorning their surroundings; and, of course, there is a friendly, neighborly competition in this regard. One neighbor after clean-up week will have a fine lawn prepared; soon you will see others doing the same. This is our experience in the last few years. For the clean-up week we interest the population for about a month; we get the police department, the fire department, the boy scouts, the women's organizations, the housekeepers' leagues, the business men, the chamber of commerce and others to cooperate. The chamber of commerce officials told me that during the last clean-up week they found a great number of fire risks in the factories and stores that would never have been found had it not been for clean-up week. This is the result of negligence on the part of the employees. Store employees throw everything in the cellars and forget to remove it; factories sweep the dirt in a corner and leave it. This clean-up idea starts the employees to clean up, and they do it completely. The city is divided into sanitary districts, and these are kept clean all the year round so far as can be seen by an ordinary examination, but in the clean-up week we preach the necessity for cleaning up the nooks, corners, attics, barns, etc. I believe that at some future time there will be no necessity for clean-up weeks, because everything will be as clean as it ought to be, because of these educational campaigns.

The Importance of Discoveries in the Field of Infectious Diseases.—The discoveries which have transformed the face of modern medicine have been in the field of infectious diseases, and in no other department of medicine could new knowledge have meant so much to mankind, for the infectious diseases have a significance to the race possessed by no other class of disease, and problems relating to their restraint are scarcely less social and economic than medical.—Welch.

DISEASE AND POVERTY *

J. N. HURTY, M.D.
INDIANAPOLIS

It seems fair to assume that the normal person will not sink into poverty. It also seems fair to assume that illness, disease, deformity and weak-mindedness are subnormal. David Starr Jordan says: "Strong men seek education and make opportunity," and to this might be appropriately added, "They bring things about; they make events occur." Weak men are the opposite of this, and by weak I mean not strong in body or in mind. It is by their works ye shall know them. Disease is itself not an evidence of physical or mental strength. Syphilis is a great cause of poverty, as it is also of insanity. "We were getting along splendidly" said the poverty-stricken woman, "until my husband took consumption." And who must be told of the great poverty that trails consumption? A farmer died of typhoid fever when the mortgage, given in part payment for his farm, was only one-half paid off. His wife and little daughter took the disease and survived only finally to fill fuller the slums of a city where she went with the child when the rich man foreclosed the mortgage. Yellow fever prevented the French from building the Panama canal, and thousands who had invested their all in canal shares were pauperized.

In Mexico there are thousands who have been made blind and pauperized by small-pox, and a writer says there are at least two million blind beggars in China, all made blind by small-pox. It is only when epidemics come, when the greater proportion of lives are threatened, that we realize the meaning of sickness and disease. The ramifications of disease are so complex and far reaching we can have but a hazy idea of what disease means.

And what is disease? Whence comes it? Infectious diseases come to us from previous cases. Syphilis, out of which inefficiency, crime, insanity and pauperism flow in increasing streams, is a disease which is acquired through sin.

A virtuous and a righteous race would not have syphilis and gonorrhea.

It is curious to note that, because of our stupidity, one's very industry may bring poverty. This is illustrated by the occupational diseases. Until very recently society permitted greed to force phossy jaw on workmen who afterward in many instances became paupers. To rear and protect industries, one product of which is poverty, is a queer condition. The prevention of phossy jaw will certainly also prevent all the poverty which might come from it.

Hernia has more than once brought an industrious citizen to poverty.

Cigar-makers, printers and tailors, are especially afflicted with tuberculosis; and on the pauper records appear the names of hundreds who have followed these occupations. A proprietor who does not surround his employees with the best conditions of health is a breeder of disease, poverty and crime.

Feeble-mindedness is a disease condition and produces a world of poverty. One from a thousand stories illustrate this. A feeble-minded girl, born of self-supporting parents, who, nevertheless, carried the taint of feeble-mindedness in their blood, was admitted to the Indiana School for the Feeble-Minded. She was there taught how to cook and to wait on the table, and to a casual observer seemed well fitted for self-support. Fertile as a rabbit, she was turned loose in the world. She mated with a male carrying her taint. In all, eight feeble-minded children appeared and the entire family of ten sunk deep into poverty. There is no cure for feeble-mindedness; it may only be prevented; and there are only two rational methods for its prevention, neither of which society will adopt. And so it happens, as we "blunder on through love and hunger," that the highest services of medical science are rejected, prevention is disregarded and disease follows civilization with its ever lengthening train of degeneracy, defectiveness, delinquency and dependency.

TUBERCULOSIS AS A CAUSE AND RESULT OF POVERTY *

S. ADOLPHUS KNOPF, M.D.
Professor of Medicine, Department of Phthisiotherapy, New York Post-Graduate Medical School and Hospital
NEW YORK

It is needless to state before physicians that direct bacillary transmission of tuberculosis is possible. Tubercle bacilli have been found in the placenta of the tuberculous mother and in the new-born babe; but when we deal with the social aspect of tuberculosis we can consider the occurrence a negligible factor because of the relative rarity of direct tuberculous heredity.

Tuberculosis in childhood we have learned to ascribe mainly to a postnatal infection from a tuberculous parent, particularly the mother, and in a small percentage (about 10 per cent.) of the cases among artificially fed babies, to bovine tuberculosis. The predisposition to tuberculosis, which is surely and often inherited, comes from what may be called a physiologic poverty. A child of a tuberculous father or a tuberculous mother brings with it as a heritage a general weakness, its entire physical make-up having the imprint of diminished resistance. In other words, it is poor in its physiologic make-up and has no natural immunity to an invasion of disease. It is particularly prone to tuberculosis and when placed in a tuberculous environment contracts this disease very easily.

It is, however, by no means necessary that both or either parent should be tuberculous in order to produce this physiologic poverty. A badly nourished mother or father, living and working under insanitary conditions, overworked and underfed, will as surely transmit a physiologic poverty to their offspring as any tuberculous parent. Numerous and rapidly repeated pregnancies, particularly in the working woman who must often labor until a few days before and resume her work a week after confinement, are also sure to produce children physiologically poor and ill adapted to resist the ever-present tubercle bacillus.

There are other diseases, such as venereal diseases, alcoholism, etc., which, when present in the parents at the time of conception, will leave the imprint on the offspring. This imprint means great susceptibility to all kinds of diseases and particularly to tuberculosis. A general debility of either one or both parents, especially when it is added to an insufficient income to support the family so that there is want of food, clothing, or proper housing, is sure to result in the physiologic poverty of the children.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

In large families of the poor it is usually the later-born child or children (fifth, sixth, seventh, eighth, etc.), who contract tuberculosis. This is primarily due to a purely physiologic condition in either father or mother, or in both. The parents are older and less vigorous, the mother particularly is worn out by the frequent pregnancies. Very often as a result of her own debilitated condition the mother cannot nurse the child, and artificial feeding, which is always worse for the child's natural growth than the healthy mother's milk, must be resorted to.

The second reason why the later-born children contract tuberculosis more frequently than the first-born is purely an economic one. So long as the family is small the father earns enough for all and the mother can devote her time to the care of the children. With the increase of the family there is very rarely a corresponding increase in the earnings of the father. The mother often has to help in the support and even then there is less abundance and less good food for the many mouths to be fed, less care can be bestowed on the later-born children, and all have to be contented with more crowded and poorer living quarters. In taking the history I always make it a point to inquire of the patient whether he was the first, second, third, fourth, fifth, etc., born in the family, and the statistics I have gathered in this way show that the later born in large families contract tuberculosis more frequently than the first-born.

Child labor, the curse of our nation, still prevalent in some of our states, impairs the physique and is in many instances the cause of tuberculosis in our young people. When the earnings of the parents are small the children will be forced into this sort of work so long as it is not absolutely prohibited by law, and when, because of tuberculosis in a family, children at the age of 8, 10, or 12 years must help in the support, working at home or in factory, they are almost certain to become victims of the disease.

We know that the housing problem is most closely allied to the tuberculosis problem. There is enough statistical evidence to show that tuberculosis is preeminently a disease of congestion. This evidence is to be found in the "lung blocks" of our large cities and the congested cheap lodging-houses, in labor camps, prisons, reformatories and schools.[1] The carefully collected statistics of the great city of Berlin show that 42 per cent. of all the cases of tuberculosis occur in families occupying but one room, 40 per cent. where they occupy two rooms, 12 per cent. where they have three rooms, and 6 per cent. where they have four or more rooms.

Maurice Fishberg[2] of New York investigated the housing condition of 217 families living in New York, the greatest and wealthiest city of our continent.

> These families consisted of 1,369 persons of whom 1,129 lived at "home" in 717 rooms and slept in 658 beds. That is about two to a bed and 1.57 people to a room including kitchens. Of the 274 tuberculous persons only 112 had separate rooms and only 136 had separate beds. Some consumptive mothers slept on chairs or on the kitchen floor.

Fishberg very justly says that this state of affairs is usual in all industrial centers of the United States. Is it any wonder that we come to look on every child born in such environments as a candidate for tuberculosis?

Not only in the homes of the poor but also among the homeless, who must be still poorer, bad housing conditions are responsible for much tuberculosis and its concomitant misery. The Health Department's statistics of New York show that the lodging-houses with an accommodation of only 17,500 people furnish in tuberculosis hospitals and clinics combined, 1,504 cases, or 8.8 per cent., of the total number reported in Manhattan, although the lodging-house population is only 0.75 per cent. of the total population. Mr. Charles B. Barnes in the *Journal of the Outdoor Life* for April, 1914,[3] shows that the lodging-house population is eleven times more subject to tuberculosis than the average population. In connection with this, I cannot help quoting from Mr. Barnes the following impressive words: "It is easy to see why so many men with tuberculosis gravitate to the cheap lodging-house. When the friendless or near-friendless man gets so weakened by his disease that he can earn little or no money, he is perforce compelled to go to a cheap place."

All cheap lodging-houses in small or large cities are evidence of poverty, misery and degradation. Those who have ever visited this class of habitation, in reality usually unfit to be inhabited by any human being, will realize that cheap lodging-houses are veritable breeding-places of tuberculosis. Many lack light, all of them lack air and proper ventilation, and not one of them is either sanitarily constructed or conducted. The tuberculous visitor to these lodging-houses will leave the traces of his tuberculosis in the form of dried sputum on the floor, wall, or blanket. The underfed, badly clad, non-tuberculous lodger, who will next occupy this cubicle, the enclosure supposed to represent a room, is almost certain to contract the disease.

The percentage of tuberculosis in our prisons and reformatories[4] is six times as high as among the population outside the prisons, which means that 6 out of every 100 prisoners, besides being condemned to serve a certain time in prison, are at the same time condemned to contract tuberculosis. And this we allow to continue in spite of our modern conception of phthisiotherapy and penology.

Congestion is of course equally detrimental in workshops, sweatshops, factories, offices and stores, and the only reason why sufficient attention is not paid to congestion in these localities is the difficulty of obtaining satisfactory statistics.

Dr. Bertram H. Waters, in a recent contribution,[5] showed how very frequent tuberculosis is among the garment workers of New York City, the majority of whom work in our crowded and insanitary sweatshops or so-called factories, located mainly in the tenement-house districts.

That tuberculosis is most prevalent among the poor, or as I may more justly express it, among those who receive low wages, is too well known to need statistical evidence; however, it is interesting to recall here the oft-quoted statistics of Hamburg which show that the highest mortality is in families with a maximum earning of $300 per year, being three times as high as in families whose income is $1,250, and about four times as high as in families earning $6,000 a year.[6] If such statistics concerning congestion and wage earning would be taken in the United States, I am sure the fact that tuberculosis is a disease of low wage would be amply shown. In the experience of a single charity society, the New York Association for Improving the Condition of the Poor, it has become very evident that the prevalence of tuberculosis is in the majority of instances the result of insufficient earning on the part of the head of the family.

Thanks to the courtesy of Mr. William H. Matthews, director of the Department of Family Welfare, I have come into possession of the advance sheet of a report soon to be published, from which I will quote the following:

> The low wages of many of the men whose widows and orphans had to be taken care of by the society may well be given as one of the reasons why many of the families were more or less dependent before the husband's death. Again, the result of the low wage, insufficient to supply the food, clothing and shelter necessary to healthful existence undoubtedly meant that the bodies of the men, women and children were exposed to diseases that especially prey on underfed, poorly clothed and badly housed people. Tuberculosis cut short the lives of 40 per cent. of these men.

Their minimum wage was $8 and their maximum wage $18 per week.

In the letter accompanying this report Mr. Matthews says:

> Generally speaking, as I read relief-case records and go in and out of the houses of our families, I am constantly depressed as I note the amount of poverty and want that comes through the presence of this disease (tuberculosis), and again with the fact that poverty seems responsible for the quick hold which it gets on so many of our families; that is, it appears in terms of both cause and effect, and it is often difficult to determine where the line between the two may be drawn.

When tuberculosis has entered the homes not only of the absolutely but even of the moderately poor, or the families of the well-to-do, it proves to be one of the most costly of all diseases, particularly if for one reason or another the patient cannot enter a public institution. In the best and most economically conducted public institutions the maintenance of a tuberculous patient costs at least $10 per week. If the tuberculous invalid happens to be the principal breadwinner of the family, poverty and suffering of all is sure to be the result, and unless the disease has been discovered early and a speedy cure is accomplished, the poverty of the family is liable to become as chronic as the disease itself.

The fallacious belief, still prevalent among the masses, that whisky will prevent and cure tuberculosis has produced a goodly number of alcoholics; while, as is well known, instead of being a preventive, alcohol is a strong predisposing factor to the disease. Of course, just as poverty may be the cause or the result of tuberculosis so alcoholism may be the cause or result of poverty. The drunkard who spends his earnings for alcohol will become a pauper. But in justice to many unfortunate sufferers among the poor, it must also be said that it is because of the horrors of sickness and poverty that some cannot resist the temptation to seek forgetfulness in the cup.

I believe what has been said thus far suffices to show that tuberculosis is as often the cause as it is the result of poverty. But whatever little merit my humble contribution may have through presenting these facts to the medical and the lay world, unless I can offer some remedy, the mere reiteration of what is known to all physicians and laymen interested in the tuberculosis cause will have little value.

Before making any suggestions, however, a word should be said on the subject of the annual cost of tuberculosis in the United States which, were it not for our vast resources, would be enough to impoverish the nation. A very careful and conservative estimate of the economic cost of tuberculosis in the United States was made by Professor Irving Fisher in 1912.[7] He estimated the number of deaths at only 155,000 per annum and considered a minimum estimate of the monetary losses which these deaths represent as follows:

Loss to the patients		$665,000,000
By sickness	$145,000,000	
By death	520,000,000	
Loss to others		570,000,000
By sickness	220,000,000	
By death	350,000,000	
Total		$1,235,000,000

As Professor Fisher told me afterward, he had not in this estimate included the cost of tuberculosis in childhood. In a paper which I presented before the Section on Hygiene of Infancy and Childhood of the International Congress on Hygiene and Demography in the same year,[8] I estimated the average duration of the life of the 50,000 children who die annually from tuberculosis in the United States as about 7½ years, and figuring the cost to parents and community for each life at only $200 per annum, the financial loss thus represented is $75,000,000; and these children have died before they have been able to give any return to their parents and the community. Add these $75,000,000 to Dr. Fisher's estimated cost of tuberculosis in adult life, we find that we are spending $1,310,000,000 for a preventable and curable disease.

Now let us see briefly what would be our financial gain if we treated all the patients, young and old, at the right time and in the right place, while the disease is still curable.

I recently attended the celebration of the tenth anniversary of the Gaylord Farm Sanatorium at Wallingford, Conn., with which it has been my privilege to be affiliated since its inception. The institution, which is supported partly by philanthropy and partly by state aid, exists for the purpose of curing the incipient and early cases of tuberculosis and restore the patients to their full earning capacity. Here is the result of ten years work, and the figures speak for themselves:

Gaylord Farm Sanatorium, Actual Earnings of discharged patients up to May 1, 1914		$1,400,000.00
Total expenditures to May 1, 1914, Lands, Buildings and Equipment	$195,958.08	
Interest on above at 5 per cent.	55,178.94	
Total maintenance	345,298.64	
		$596,435.66
Excess patients' earnings over expenditures		$803,564.34

These statistics are carefully compiled by Dr. David R. Lyman, the able superintendent of the sanatorium, and I vouch for their accuracy.

[8] Knopf, S. A.: Tuberculosis and Other Diseases in Schools and Colleges, New York Med. Jour., Jan. 25, 1913.

It is by carefully tracing and watching over the patients discharged from the institution that Dr. Lyman and his co-workers have been able to gather these statistics. It is by keeping tab on all the patients who pass through tuberculosis clinics, dispensaries, and hospital sanatoriums that an infinite amount of good in the aftercare of the cured patients or those in whom the disease is arrested can be accomplished. I go even further, however, and say that in order that our institutions, sanatoriums, hospitals, clinics, dispensaries, and preventoriums for the tuberculous adult or child shall be really effective in diminishing the number of cases and thus prevent tuberculosis from becoming the cause of still more poverty, the home of the patient should be visited by a social worker, not only after the tuberculous patient has passed through the sanatorium and graduated therefrom, but on the day of entrance. By an investigation of the home life of the individual admitted to an institution we should find out why that man, this woman, or this child became tuberculous, and immediate steps should then be taken to remove the cause and thus prevent other members of the family from contracting this costly disease with its wake of suffering, misery, and death.

The next and most important thing for us to do is to teach the masses that quality is better than quantity in the raising of a family. A universal and periodic examination of all citizens for tuberculosis and other poverty-producing diseases should be made obligatory; the poor should be examined free and the well-to-do should pay a reasonable fee. All individuals discovered to be tuberculous should be placed under medical care. Predisposed children should be educated in preventoria and open air schools. The pregnant woman should not be allowed to work as a wage earner for two months before and for one month after confinement.

In view of the fact that thousands of grown-up men and women are seeking work, there is not the slightest excuse for the continuation of that abomination and disgrace to our nation known as child labor. State and municipal labor bureaus should be established to send those seeking work where workers are needed. A minimum wage law should be established and be framed so as to assure a living wage to every living citizen.

To improve the housing conditions of the masses we must have better housing laws and their more rigorous enforcement. But that alone will not suffice. Our philanthropists, big and little, must listen to the call of duty and help to build more model tenement houses or individual sanitary homes for which the rent shall be low, and not keep the land unoccupied for speculation until greater congestion shall have increased its money value.

For the homeless man, there should be decent public places where for a reasonable sum he may find sanitary living quarters by day and by night. The employers of men and women in factories, workshops, stores, and offices must bear in mind that light and air and reasonable working hours increase efficiency and make their employees more loyal and helpful. Our brothers and sisters, morally diseased and confined in prisons, should also be thought of in our combat of tuberculosis. Congestion, underfeeding, bad sanitation, and bad treatment of our prisoners will react inevitably on the health, happiness, and prosperity of the community. The more sanitary are our prisons, the less crowded and congested they may be, the more humane we are in the treatment of the inmates, the more of these unfortunates will be redeemed. In short, unless there is more humanity and social justice, a more wise administration of all 'round state and municipalities, a greater willingness of our well-to-do citizens to help in overcoming tuberculosis as a disease of malnutrition, bad housing, and low wage, we will continue to have tuberculosis as a most frequent cause of poverty, and poverty again causing tuberculosis, and we will continue to lose 200,000 valuable lives annually, representing a loss of nearly a billion and a half dollars to the community.

It should be considered the duty of every municipality to teach the masses temperance, sanitary living and how to prepare nutritious food.[9] This should be done by means of popular literature, lectures and demonstrations. To relieve the underfeeding of the masses, I favor such institutions as are known in Germany as *Volksküchen*, that is to say, public kitchens where substantial, nutritious meals for an entire family can be purchased at a minimum price.

I cannot conclude this report on tuberculosis as a result and cause of poverty without referring to one feature which has been thought of very little, except perhaps by those who look on the tuberculosis problem in all its aspects from a medicosociologic point of view and which was expressed eloquently and forcefully in a recent address by Deputy Health Commissioner Haven Emerson of New York.[10] Many corporations, employers of large bodies of men and women and even some state and municipal departments now require a physical examination for tuberculosis before they accept any one in their employ. By this precaution these corporations, employers and governmental departments surround themselves with those physically best fit to do their work. What is the result of this ever increasing and from some points of view most laudable practice of examining all candidates for employment and excluding the suspected or tuberculous? Are we are creating a large army of persons declared by this exclusion unfit for the struggle of life? Tuberculosis must then also be held responsible for this source of increasing poverty among the seemingly unfit. It is a tremendous problem which thus confronts our statesmen and political economists, and indeed all of us. At this time I feel myself not prepared to suggest any other solution, except the inauguration of universal and obligatory insurance against disease, infirmity and old age (including, of course, tuberculosis) by state government or by private insurance companies under state control, similar to those in Germany for all working men or women earning less than $1,000 per year. There should be also encouraged a voluntary insurance by those earning more. For the insurance for the former class the employer should be held responsible.

As an additional means to provide sufficient sanatorium and hospital facilities, a special tuberculosis tax should be levied on house and factory owners enabling the municipal authorities to construct, equip and maintain such much needed institutions, because of the very beneficent examination for tuberculosis of many employees and workers and their exclusion if found afflicted with the disease. Lastly, I would wish to make as strong and as earnest an appeal as possible to statesmen and philanthropists for the establishment of industrial colonies in which such unfortunate workers may have an opportunity not only to support themselves and their families in decency, but by which the opportunity for their complete reestablishment to health and vigor may also be afforded.

[10] Emerson, Haven: Address at the dedication of the Mt. McGregor Sanatorium for Tuberculosis Employees of the Metropolitan Life Insurance Company.

As a conclusion to this necessarily rather meager report on a great and overwhelming theme, permit me to quote the following paragraph from the "Tuberculosis-Day Prayer" of my inspired friend, Professor Walter Rauschenbusch of Rochester, N. Y.:

> O God, we pray Thee for all whose vigor is being drained by slow and wasting illness. . . . Since we are all jointly guilty of the conditions which have bred their disease, may we stand by those who bear the burden of our common sin and set the united will of our community against this power that slays the young and the strong in the bloom of their life. May this death that creeps from man to man be a solemn reminder that we are all one family, bound together in joy and sorrow, in life and death, that we may cease from our selfish indifference and together seek Thy kingdom and Thy righteousness which will bring us health and life.

16 West Ninety-Fifth Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. KNOPF AND HURTY

Dr. Woods Hutchinson, New York: Poverty is a medical problem, first, because of the heavy part that disease plays in its production. The most laborious and carefully thought-out report of the recent English Royal Commission on Poverty states that, in the commissioners' judgment, at least from 55 to 60 per cent. of the poverty in Great Britain is due to one cause—sickness. The same finding has been repeated time and again by other investigators; for instance, the Charity Organization Society of New York investigated cases of unemployment and destitution. In one winter, of 2,200 families investigated, 35 per cent. were found to be in destitute condition on account of tuberculosis, and 25 per cent. more on account of other diseases. A committee of equalization, to see that every child born into the community shall have everything that it needs in the way of food-supply and education before anybody is allowed to have too much seems to me very urgently called for under the circumstances. As disease and ill-health are such important factors in the causation of poverty, attempts have been made, in most of the civilized countries of Europe, to provide for the medical care of the poorer and less successful elements of the population by some form of government health insurance. It is only a question of time before some such process is brought up for consideration and action in this country. We ought to prepare ourselves to meet that movement and have a body of facts on which we can base our view of what we think ought to be done that every individual may get the best possible medical attention and the protection against disease to which he is entitled. I would suggest that it should be made in some way possible for physicians, particularly younger men, to experiment with some form of annual contract or health insurance on terms to be determined by this organization, including a physical examination at stated intervals, and an inspection of the home and place of work. It can be done for a comparatively small sum because it brings under contribution the considerable percentage, ranging anywhere from 15 to 25 per cent., of the community whose medical care we now perform for nothing through charity, or hospitals, or through uncollectable bills, etc. If we could devise some scheme by which the poorer classes of working men who often cannot afford to pay a $2 fee for a visit can have the benefit of a physician's care by coming into some organization provided and planned by the doctor himself it would be a great addition to the health of the community. This Section should appoint a committee, or should request the House of Delegates to appoint one, to study this problem and see under what conditions some voluntary system of yearly or contract practice could be entered into. The sum that could be fixed for those in poorer circumstances is really much smaller than one would readily believe. The amount fixed under the Lloyd-George bill in England was 8 shillings and sixpence a year—a little over $2; and the physicians of England were making a rate of 5 shillings a year in voluntary organizations of their own and made fairly good and so-called remunerative incomes out of their private clubs.

Dr. Edward O. Otis, Boston: Dr. Knopf has said that tuberculosis is preeminently a disease of congestion of population. I should like to modify that statement and say, it is a disease of the conditions which congestion produces. I think it is a mooted question with us whether or not people can keep in health under congested conditions of city life. One thing is sure, we are never going to get the poor of our larger cities out into the country, and I think that what we must do is to make living conditions wholesome under congested conditions in the cities. We have found out now that it is not foul or stagnant air that is particularly injurious, provided we can keep it moist and in motion. We have learned, also, that tuberculosis may exist quite as extensively in the country districts as in the congested city. I was told some years ago by the commissioners of Minnesota who were appointed to look into the question of tuberculosis with the idea of establishing a sanatorium, that the largest amount of tuberculosis that existed in Minnesota was not in the two cities of St. Paul and Minneapolis, but among the Scandinavian farmers. I have practiced among the poor, as my friend Dr. Knopf has, for a great many years, in a large city among the people of the slums in dispensary work, and I have often found, as I dare say all have who have had similar experience, that the number of children in a poor family was the salvation of that poor family; that when the father was disqualified from working for one cause or another, he was kept from poverty by the children taking up the burden of the family support. I agree with Dr. Hutchinson, that if we can only give the children of these large families a fair chance, they will grow up as healthy and well, and as useful citizens to the community, as the one child of quality, so to speak, in the one-child family, who is not infrequently a failure. Indeed, with us in Boston, unless we had had the immigrants and the large families of the immigrants, the population, so far as the Anglo-Saxon portion of it was concerned, would have been a decadent one, for the purely American race is rapidly dying out. I think we have great hope in the large families of the poor if we can only make their congested condition of living wholesome ones.

Dr. S. A. Knopf, New York: I can but disagree with my friend, Dr. Otis, when he thinks that the so-called modern idea that we can dispense with fresh air so long as the air is in motion and properly saturated is a correct one. I for one will not subscribe to it, and I consider it a dangerous doctrine to teach, at least when we deal with tuberculous patients. Granting even that the exhalation of carbonic acid gas from our lungs is not as injurious as we formerly considered it, there is something decidedly beneficial in outdoor fresh air which cannot be found in the confined air, no matter how much it may be in motion; hence I would strongly protest against any change in our conception of the danger from congestion and I would equally protest against teaching that outdoor fresh air is not so essential to our well-being or the treatment of tuberculosis as was formerly thought. On the contrary, let us continue to preach and practice outdoor sleeping and outdoor living as far as possible. I have no time to enter into lengthy discussion as to the advisability of small families among the poor, the undernourished, and the tuberculously inclined; all I can say is that in my experience among the tenement dwellers in New York I found that in larger families among the poor, particularly where there was tuberculosis, the children die young, but not before they have caused their parents a good deal of sorrow and anxiety and cost the municipality a good deal of money, and all in vain. This, to my mind, is more race suicide than the prevention of conception in a tuberculous mother. To prevent such a conception I believe is the physician's duty, and I am willing to take the responsibility before the law and my God for every time I have prevented the procreation of a tuberculous offspring and thus perhaps have, if not saved, at least prolonged the life of a mother.

SOME EXPERIENCES WITH ALCOHOL INJECTION IN TRIGEMINAL AND OTHER NEURALGIAS *

WILFRED HARRIS, M.D.
LONDON, ENGLAND

It is a great pleasure to me to be enabled, through the courtesy of the officers of your Section, to place before you the following observations on the alcohol injection treatment, and I hope to learn much from your experiences and criticism. Schlösser's brilliant idea of injection of the main branches of the fifth nerve at their deep foramina, with strong alcohol, has now been on trial for ten years by workers in all countries, and clear indications for its use, and when to avoid it, are now capable of formulation. My personal experience of the method now dates back six years, the first case in which I used it being literally equivalent to a laboratory experiment on a human nerve.

A woman suffering from strong hemiplegic contracture of the fingers was unable to use her extensor muscles of the wrist and fingers, on account of the strong flexor spasm instantly induced. Under local anesthesia with eucain, I therefore dissected out the median nerve above the elbow, and injected it with 5 minims of 80 per cent. alcohol, using a fine hypodermic needle. Instantly the flexor spasm and contracture were relaxed, and she was able at once to extend her wrist and fingers; at the same time analgesia to pin-prick and anesthesia to cotton-wool developed over the anatomic distribution of the median nerve on the hand, while a week later typical reaction of degeneration to electrical testing became evident in the flexor muscles and thenar eminence. Such a result was as good evidence as can be required of the destructive effect of strong alcohol, both in sensory and motor nerve-fibers, and impressed on me, which is by no means yet well understood, that alcohol must not be injected into a mixed motor and sensory nerve, such as the sciatic, for the treatment of pain, on account of the motor paralysis and foot-drop which will certainly ensue.

Many patients who have thus been operated on have escaped paralysis by their good fortune of the operator missing the nerve-trunk and making the injection outside the nerve-sheath. When using this injection in the treatment of chronic trigeminal neuralgia, it is only the third division which contains any motor fibers, and the paralysis of the masseter, temporal and pterygoid muscles resulting from a properly placed injection in the foramen ovale is of small account, owing to the mandible being served by the corresponding muscles of the other side, and also to the fact, when the third division on one side is made completely anesthetic on the lower jaw, lower lip and half of tongue, such patients invariably eat on the other side of the mouth entirely.

In two patients with bilateral trigeminal neuralgia in whom I have injected the foramen ovale on each side at the same sitting, there has been difficulty in chewing and closing the jaw for a few days.

I have had experience with some 200 cases of *chronic trigeminal neuralgia.* The first division, in this type of neuralgia, is very seldom involved alone, pain in the second division being its invariable accompaniment sooner or later, though I have known the neuralgia limited to the supra-orbital distribution for three years before the second division became involved. In one such case, a woman whom I injected four years ago, I first injected the second division at the foramen rotundum, causing deep and complete anesthesia on the cheek, upper lip and upper gum; pain ceased from that moment in the second division, but continued severely above the eyebrow and on the top of the head. I then injected the supra-orbital nerve at the notch, causing deep anesthesia on the forehead and top of the head, with the resultant loss of all pain except over a small area, the size of a shilling, at the back of the anesthetic area on the top of the head, at its junction with the great occipital distribution; here the pain continued in unabated paroxysms, which ceased entirely and permanently with a hypodermic injection of alcohol under the scalp at this area. She is now, four years afterward, still perfectly well and free from pain. This is the only case I have seen of chronic trigeminal neuralgia in which such a local painful area persisted at the extremity of the anesthetic area.

Somewhat resembling the latter case, however, was that of a woman who struck the top of her head a violent blow against a low doorway.

Though feeling very shaken, she went out to dinner that night, but had to leave suddenly owing to faintness and vomiting. Ever since that time she became subject to paroxysmal attacks of intense pain, every few days, referred to the exact spot on the top of the head which she struck. When I saw her two years later, this area was slightly tender, and pressure on it started a slight attack of pain. I therefore recommended her doctor to inject this area hypodermically with strong alcohol, which he did twice, with a week's interval. This cured her pain, and she has never had another attack.

The supra-orbital is the only branch of the first division which I attack, and I have never attempted to reach any other branch within the orbit, as I consider this both dangerous and unnecessary.

The second division, or superior maxillary nerve, may be injected with advantage, either at the foramen rotundum in the sphenomaxillary fossa, or at the exit of the infra-orbital nerve on the cheek. The latter foramen is usually quite easy to find, a needle 3 cm. long being pushed through the cheek at the level of the upper border of the ala nasi, and 0.5 cm. external to it. The needle usually finds the foramen in a direction upward and outward from this point.

A certain amount of swelling and edema of the lower eyelid and cheek always result from this injection, lasting from one to two weeks. This injection may be sufficient to abolish all the pain in certain cases of trigeminal neuralgia affecting the second division, in which the pain is limited to the skin of the ala nasi and lip, when the lightest touch on the lip or nose may start paroxysms.

In the majority of cases, however, the pain is also referred to the upper jaw, and sometimes to the palate, and in these cases the destruction of the infra-orbital nerve will fail to give complete, or even much relief. The superior maxillary nerve must then be attacked farther back at its exit from the foramen rotundum, in order to inject it at a point before it has given off the posterior dental branches, and the sensory branch to Meckel's ganglion and the palate. This is a difficult injection to perform properly, so as to cause deep anesthesia of the whole nerve, and it is more difficult to be sure of one's results after the infra-orbital nerve has already been made anesthetic by the peripheral injection. If, therefore, a second division neuralgia clearly involves the upper jaw, as well as the skin of the nose and lip, as it does in the majority of cases, attempts should be made to inject the nerve at the foramen rotundum before injecting the infra-orbital canal.

---

* Read before the Section on Nervous and Mental Diseases at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

I use two routes for this posterior injection; the first, and preferably, through the cheek in front of the coronoid process and behind the superior maxilla. Sinking the needle as close as possible to the bone at a point about 6.5 cm. measured from the middle of the external auditory meatus, a 3 inch needle, 0.8 mm. caliber, is directed upward at an angle of 40 degrees, and backward in a line with the ascending orbital process of the malar bone. At a depth of about 5 cm., the needle either strikes the external pterygoid plate, or slips in front of its anterior border into the sphenomaxillary fossa. The pterygoid plate is a useful landmark, as the foramen rotundum lies barely more than a centimeter internal to its anterior border; if, therefore, I find that my needle slips into the fossa without first striking the plate, I withdraw my needle slightly and feel backward with the point for the plate, noting then the depth to which my needle has been sunk. Then maneuvering the point in front of the edge of the plate, I push the needle onward in the same line to a further depth of not more than 1.5 cm. If the needle has been fortunately directed, the nerve will be struck, the patient indicating this by flinching slightly and complaining of pain either deeply at the site of the needle, or else referred to the nose, lip or cheek. It is, I think, quite as common for the twinge of pain to be referred only deeply, and not along the distribution of the nerve. I then inject 3 or 4 minims of 5 per cent. novocain solution, the patient instantly feeling a sensation of a spray over the face, and after two or three minutes light anesthesia will develop on the lip and cheek. Whether this is so or not, I change syringes now, and inject a few minims of 90 per cent. alcohol, taking great care to hold my needle perfectly steady.

Certain difficulties may be encountered in attempting this route for injection of the second division, owing either to the coronoid process of the mandible coming far forward, or to the bulging backward of the antrum in the maxilla. Indeed, it may be impossible to direct the needle between these parts, and in front of the external pterygoid plate, so as to enter the sphenomaxillary fossa. In these cases I then try for the nerve from behind the coronoid process, passing my needle through the cheek about 4 cm. in front of the middle of the external auditory meatus, on the line drawn from the incisura notch to the bottom of the ala nasi, so as to pass over the bottom of the sigmoid notch on the lower jaw. The needle must be pushed in slightly upward and forward, the external pterygoid plate felt for and so on, as already described. With this route there is probably less risk of hematoma from wounding the internal maxillary artery, though the nerve will be hit usually in front of the branch to Meckel's ganglion, instead of behind. Consequently there will be in these cases no anesthesia produced of the palate.

In some cases in which the pain appears limited entirely to the second division, the neuralgia may continue unabated after a successful injection of this division, and disappears only and finally when the third division has also been injected at the foramen ovale. Thus, a man, aged 71, had the infra-orbital nerve divided and torn out for second division neuralgia; after complete freedom for three years the pain then returned in the nose, lip and upper gum with great severity, though the skin of the cheek and lip was totally anesthetic. I tried injection of the second division, both posteriorly and at the infra-orbital foramen, but failed to make any impression on the neuralgia. I then injected the third division at the foramen ovale, causing complete anesthesia of its distribution, the pain disappearing from that moment for two years, since when slight warnings of pain are recommencing.

Much more certain than injection of the superior maxillary nerve is injection of the third division at the foramen ovale.

For this I use roughly Levy and Baudouin's line. Here again, as I have mentioned for the second division, perhaps more often than not when the nerve is struck by the needle, the patient complains of pain situated deeply where the needle is, rather than in the lower lip, jaw or tongue. If my needle is in the right direction, very slightly backward and upward, and at the right depth, varying from 1⅝ inches to 2½ inches, according to the width of the head and fatness of the cheek, when the patient flinches I carefully withdraw the brass wire stilet from my needle, and inject a few drops of 5 per cent. novocain. If any resistance to the push of the piston is felt, the needle may be within the nerve; but if not, I push the needle slightly deeper, and inject a few more drops. I then, after a minute or so, change my syringe and inject a few drops of 90 per cent. alcohol, as already described. Then, after half a minute or so, testing with a pin the lower lip and tongue, the presence or absence of anesthesia is a sure test, as to whether the nerve has been properly injected or not, and the needle must be slightly withdrawn and tried in a fresh direction, until deep anesthesia results from the injection. Rarely is there any risk of hematoma in this method of reaching the foramen ovale, the only artery liable to puncture being the middle meningeal; but I have never known it give any trouble. The internal maxillary artery is usually well protected, as it turns inward well below the level of the sigmoid notch.

When working with the needle to find the nerve, the stilet should always be kept pushed within it up to the point, in order to keep any drop of blood from entering the caliber of the needle. When it is thought that the needle is correctly placed, and the stilet is taken out in order to fit on the syringe, if blood should drip from the needle, the needle should be instantly withdrawn and washed out with saline, as its point cannot have been within the nerve, and if alcohol were then injected through the needle it would instantly cause firm clotting to occur within the needle, so that no further injection could be done. If the needle is directed too far backward, pain may be complained of deep in the ear, owing to the needle pricking the eustachian tube. When this occurs, the needle should be at once withdrawn slightly, and the nerve searched for a little more forward. Care should be taken never to inject alcohol into the spot when pain is complained of deep in the ear, as complete deafness of that ear, due to eustachian obstruction, may be produced, lasting for many months. This characteristic pain must be distinguished from pain referred to the external ear, which is sometimes produced when the auriculotemporal branch of the third division is struck by the needle close to the foramen ovale; in the latter case the needle should be thrust in for another millimeter, and the novocain and alcohol injected, as already described, when anesthesia will probably soon be produced over the whole area of distribution of the third division.

It may be that all this time the needle has not touched bone at all, but I prefer to feel the under surface of the sphenoid with the point of the needle, as it is a good landmark for the level of the foramen, and the needle may be sometimes slipped along it into the lips of the foramen. Two other bony landmarks I also find of service. Posteriorly, the needle will engage the spine of the sphenoid at less than the required depth, and the bone will be felt to slope deeply inward. This may be used as a guide to the foramen, which lies just in front and above. In a few cases even prolonged searching does not discover the nerve at the foramen, when the usual direction has been first explored, and another bony guide which may then be tried is the external pterygoid plate, by pushing in the needle in a slightly anterior direction, when it should be struck at a depth of 4 or 5 cm. Then, with a slight sawing movement, the point of the needle should be made to slip off its posterior edge, when the foramen may be reached above and behind this point. Occasionally, in abnormally shaped skulls, the foramen may be found much farther in front of the ordinary line than is usual, and in yet others, particularly in small heads of women, the line to the foramen may be directed backward at a much greater angle than usual, quite 30 degrees. In the latter type difficulty may be experienced on sinking the needle in the usual direction, by the point of the needle striking bone, which seems to block the needle in every direction. This is the external pterygoid plate, and the needle must be turned considerably more upward and backward to reach the foramen ovale. Before I recognized this condition, I mistook this bone for the spine of the sphenoid, and in two cases, while searching forward for the foramen ovale, my needle slipped in front of the external pterygoid plate, and struck a nerve, which I then injected, and found to my astonishment that I had produced anesthesia of the second division, when I had been searching for the third division at the foramen ovale.

Another small accident that may be met is that when the needle is directed too low, without taking the under surface of the sphenoid as a guide, the wall of the pharynx may be punctured. The patient will indicate this by complaining of pain in the throat, and if the injection of alcohol be made now, he will at once complain of burning sensation on the back of the tongue. The needle should be at once withdrawn a centimeter or more, and I have never known any harm to result from this.

Although in certain cases, peripheral injection of the infra-orbital nerve may control for a time neuralgia of the second division, I do not consider that injection of the mental foramen is of any real service in neuralgia of the third division. It is a very difficult foramen to find, and even though it be properly injected, the resulting anesthesia of the lower lip and chin does not in any way diminish the pain in the lower jaw, ear or tongue. I never therefore now inject this foramen, but always attack the third division at the foramen ovale.

INJECTION OF THE GASSERIAN GANGLION

When first I practiced injection of the foramen ovale on the dead body using the method already described below the zygoma, I found, practically invariably, that when the needle point was placed within the nerve at the lips of the foramen, without pushing the needle through the foramen, injection of solution of methylene blue infiltrated the whole gasserian ganglion, the stain even surrounding the walls of the cavernous sinus, and even spreading down the anterior surface of the pons. Clinically I have thus injected the ganglion in scores of cases, anesthesia first appearing over the third division, and as more alcohol is injected, a few drops at a time, the anesthesia spreads over the second and first divisions until, after using 1 to 1.5 c.c., the whole territory of the fifth nerve has become anesthetic. The patient indicates this spread of the alcohol by slight burning pain being felt around the eye and top of the head, and on testing with a pin there will be found total anesthesia to pin-prick and to pressure over the whole front of the head on one side, including the eyeball. If the alcohol has been slowly injected a few drops at a time, the anesthesia being tested after each injection, this total anesthesia will begin to fade away after a lapse of five or ten minutes from the first and second divisions, and an hour or so later, or the next day, there will be found slight analgesia on the forehead and cheek only, while total anesthesia persists over the third division.

It is important not to inject more than a few drops of the alcohol at a time, and to wait at least two minutes for testing the anesthesia on the forehead before pushing in any more alcohol. As soon as total anesthesia develops over the forehead and eyeball, there is a possibility that the damage to the ganglion-cells may be so great that the total anesthesia does not evaporate, as is usually the case, though in the majority of cases as much as 0.5 c.c. alcohol may be further injected after total anesthesia appears, without risk of its being permanent. When a total of more than 1.5 c.c. has been injected, this risk is a very real one, and if total anesthesia still persists half an hour after the injection, the eyelids should be closed by rubber plaster and a pad and bandage, in order to prevent the risk of keratitis developing, which is certain to appear on the following day if total anesthesia is still present. If, however, sensation is returning on the first division and pressure on the eyeball can be felt definitely, then the risk is past. When, however, the anesthesia is still complete on the following day, then it is practically certain to persist for weeks or months, and the eyelids should be sewn up, leaving a chink at either canthus for washing out the palpebral cavity with saline. So long as the lids are kept closed, keratitis will not develop, and even a certain degree of keratitis which had developed, previous to the sewing up of the lids, will clear up. I have been forced to have this treatment adopted in seven patients whose ganglion I had injected by this method. The cure of the neuralgia is, however, certain, and likely to be permanent, though my first case of injection of the ganglion dates back only four years.

In many subjects it is possible to push the needle through the lips of the foramen ovale into the ganglion itself, though this is rarely necessary. A curious point, which I am unable to explain, is that after the ganglion injection which I have described, the anesthesia on the first division is more intense and more lasting than even on the second or third divisions, a point which is peculiarly unfortunate, owing to its dependent keratitis.

In over sixty cases in which I have thus injected the gasserian ganglion, in one case slight diplopia, due to sixth nerve weakness, developed immediately, and did not disappear entirely until three months had elapsed. This was presumably, due to alcohol infiltrating the outer wall of the cavernous sinus. In one other case a curious result occurred which I cannot explain. In a woman aged 64, with chronic trigeminal neuralgia affecting all three divisions on the left side, which had begun three years previously with neuralgia limited to the first division, I injected the third division and the ganglion as described above. As total anesthesia developed, she became giddy and swayed slightly to the left, and coarse rotatory nystagmus toward the right side, with left facial paresis and total left nerve deafness, appeared. There was no trace of loss of consciousness, and the vertigo disappeared after a few minutes; the nerve deafness had disappeared within an hour, and the next morning the facial paresis and nystagmus were scarcely noticeable, and both had completely disappeared in five days, and she felt perfectly well. Though it is possible to conceive that the alcohol might spread along the ventral surface of the pons and involve the seventh and eighth nerves, yet the nystagmus would suggest a central lesion, cerebellar or nuclear.

PATH OF THE TASTE FIBERS

One of the striking results of my series of injections of the third division at the foramen ovale and of the gasserian ganglion has been the very large proportion of cases in which immediate *loss of taste* has developed on the anterior half of the tongue on that side. With almost monotonous regularity my experience has been to find loss of taste to all forms develop immediately on the anesthetic half of the tongue, in proportion to the depth of the anesthesia. I have taken the utmost care in the testing of these patients, and there can be no possible doubts of my results. This loss of taste, as I have said, develops immediately, and the sensation of taste remains absent so long as the anesthesia of the third division persists, and I have seen loss of taste well marked twelve months and two years after injection. In three or four cases I have seen sensation of taste partially present, though obviously diminished, when the tongue showed deep anesthesia, though the auriculotemporal portion of the third division had escaped almost entirely. In five cases only have I seen almost normal acuity of taste persist when all three branches of the third division were deeply anesthetic.

With one exception, in all my cases of injection of the gasserian ganglion in which deep anesthesia of the whole fifth area was produced, there was complete loss of taste on the half of the tongue.

Curiously, in the last ganglion case I injected, four days before I sailed, although there was total fifth anesthesia, taste was scarcely affected, though the anesthesia was total and persistent, necessitating sewing up the eyelids, on account of commencing keratitis.

Leaving these cases aside for the moment, the immediate loss of sensation of taste produced by injection at the foramen ovale is certain proof that in the large majority of persons, the taste fibers from the tongue pass along to the gasserian ganglion by the third division, since the result is immediate and can not therefore be due to any vascular changes, the result of nerve degeneration, as Cushing has tried to explain the loss of taste he has found after gasserectomy. At the same time, we know that the taste fibers do not pass with the lingual nerve, but leave that nerve by the chorda tympani and run in conjunction with the facial nerve in the middle ear, to the geniculate ganglion. So far the afferent course of these gustatory fibers is beyond dispute, and it is their path from the geniculate ganglion to the pons which has been the subject of much argument. Various routes have been given for these fibers, the one now most in favor being along the pars intermedia of Wrisberg to the gustatory nucleus of the glossopharyngeal.

There is really no clinical evidence for this statement whatever, indeed, what evidence there is is entirely against it, and the chief reason in support of the statement is an analogy between the geniculate ganglion and the pars intermedia of Wrisberg on the one hand, and a spinal posterior root and its ganglion on the other. Now, my results show that in at any rate the majority of cases, the normal path for these taste fibers lies in the third division of the fifth nerve at the foramen ovale. Therefore the gustatory fibers must pass from the geniculate ganglion to the foramen ovale, and the only possible path appears to be along the small superficial petrosal nerve to the otic ganglion.

In some cases I have found that taste was also completely absent on the back of the tongue and palatal arches as well as on the front of the tongue; in others taste was notably diminished on the back of the tongue, and in a few, perhaps one-third, there seemed no loss of taste at the back. Since I have found in three of my cases of complete third division anesthesia that taste on the tongue was scarcely interfered with, I can only assume that in a small proportion of persons, the gustatory impressions from the tongue must pass from the geniculate ganglion along a different route, either by the pars intermedia of Wrisberg, or by the tympanic plexus and the glossopharyngeal nerve.

Bilateral Trigeminal Neuralgia.—True chronic trigeminal neuralgia is occasionally bilateral, in ten of my patients, or 5 per cent., this being the case. In four of my patients it affected both sides before any injection or other operative treatment had been done. In two others it appeared on the right side nine years and four years after gasserectomy had been performed on the other side. In two of the foregoing four cases I injected the foramen ovale on each side for bilateral third division tic at the same sitting, causing total anesthesia of the front of the tongue. This interferes considerably with articulation for a few days, one of the patients—a man—being unable to make his words intelligible for several hours. In the other patient—a woman—paresis of the masticatory muscles was more noticeable, she being unable to close her mouth the first day, and for a week or ten days she could not chew her food.

Geniculate or Otic Neuralgia.—My attention was first drawn to this form by reading the most interesting work of Ramsay Hunt on the sensory supply of the seventh cranial or facial nerve, and also the description by Pierce Clark and Taylor of their case of obstinate tic said to be cured by division of the pars intermedia of Wrisberg. Excluding those cases, not very uncommon, in which severe neuralgia in front of the ear accompanies facial palsy, or herpes within the auditory meatus, possibly due to geniculate inflammation, I have encountered two patients who suffered from almost identical paroxysmal neuralgia, which had lasted for eleven and ten years, respectively, in which the paroxysms of pain began in the throat or posterior palatal region on one side, and spread into the ear and in front of the ear on to the cheek, and down the side of the neck. The sudden onset and intensity of the pain, and the recurrent paroxysms closely resembled chronic trigeminal neuralgia, but the distribution of the pain made me doubtful as to their dependence on the fifth nerve, and in each case no alleviation was produced by a successful injection of the third division of the fifth. One of these patients was a man of about 48, who had suffered eleven years, the other an old lady of 87, who had had the attacks for nine years.

I have known the pain following geniculate herpes to be most intense and prolonged for many weeks, in a man of 44, without any facial paralysis. This case was sent to me by an aurist, and the herpetic vesicles were still visible on the tympanum and posterior wall of the meatus, ten days after the onset of the pain.

Postherpetic Neuralgia.—This should never be treated by alcohol injection, or by any other operative measure. The most frequent cases that are thus sent to me are the cases of frontal herpes affecting the ophthalmic division of the fifth. Sometimes the destruction is so great that total anesthesia of part of the forehead and top of head is produced; in others only slight numbing and sensation of tightness is felt. The pain varies in severity from a feeling of crawling and similar paresthesias to quite severe paroxysms, though less sudden and severe than in the case of chronic trigeminal neuralgia. Any injection or operative treatment in my experience makes these patients worse, though there may be apparent improvement for a day or two. The same may be said for postherpetic neuralgia affecting the second and third divisions, and the whole of the fifth, which are less common, and also postherpetic neuralgia of the trunk.

I have not yet performed injection of the gasserian ganglion for severe posthepetic neuralgia of the fifth, though theoretically it might effect a cure, yet not certainly so, as the lesion may be partly central and not only in the ganglion, as I have known division of posterior spinal roots fail to give relief in postherpetic neuralgia of the trunk.

Chronic Fibrositis.—This condition of the shoulder, back, buttock and sole of the foot may sometimes derive almost magical relief from alcohol injection. In many cases in which the pain had continued for years, seven years in one case, I have seen it disappear instantly and permanently after alcohol injection. This is perhaps most striking in the cases of plantar fibrositis following rheumatism, the patients being hardly able to stand or hobble about for months, owing to the pain produced by their weight stretching the plantar fascia and ligaments. In five such cases I have produced instant relief, so that the patient could not only walk with comfort, but jump about within five minutes of the injection. My method is to search for points of deep tenderness on pressure and mark them carefully. Then after sterilization with iodin, I sink a fine needle vertically down to the bone, injecting a few drops of novocain on the way. After half a minute 10 drops of 90 per cent. spirit is injected and the needle withdrawn, and the puncture sealed with collodion gauze. Sometimes three or four spots have to be injected, and occasionally a repetition is necessary next day or later, owing to the whole of the affected area not having been covered.

I do not find that this method is of any value in cases of diffuse tenderness, excepting when definite spots of intense tenderness are found. This is sometimes the case in fibrositis of the buttock and occasionally it may accompany a true sciatica. When using this treatment by alcohol injection for fibrositis of the buttock, great care must be taken not to inject the sciatic nerve itself with the drug. I may mention that I also use the treatment of injection of the sciatic nerve itself in some sciaticas with novocain and saline from 50 to 100 c.c.

In chronic *brachial fibrositis,* which is less common, I have also successfully used alcohol injection in six cases; here again precautions must be taken against injecting a nerve-trunk with alcohol. My method, after sinking the needle to the bone in the required spot, is to inject a few drops of novocain 5 per cent., and if no motor weakness or anesthesia has appeared within a minute, I then follow it with the alcohol. In suitable cases of this type the benefit and relief are immediate and most striking.

We are now in a position to weigh our results and to give a definite opinion as to the beneficial effects, or otherwise, of alcohol injection for neuralgia. In certain cases of chronic fibrositis of the buttock, trunk, shoulder, forearm and sole of the foot, it may effect an immediate and lasting cure of the pain, and, when properly used, never does any harm.

Among the cranial neuralgias, periodic supra-orbital neuralgia, such as the postinfluenzal form, with daily recurrences of pain for hours, may be completely cured by a single injection. The pain of inoperable carcinoma of the tongue may also be completely relieved by injection of the third division at the foramen ovale. Migrainous neuralgia, though often mistaken for chronic trigeminal neuralgia, is only rarely benefited by this treatment. Postherpetic neuralgia, whether of the face or trunk, should never be treated by alcohol injection. It is in chronic trigeminal neuralgia that the largest proportion of cures are wrought by this means, and practically its only rivals are neurectomy and gasserectomy. The former gives us no longer relief than neurolysis by alcohol injection, and the treatment cannot be repeated at the same place. With gasserectomy there is the necessity of a severe operation under an anesthetic, with a permanent scar, and the possibility of facial palsy, the frequency of keratitis and of permanent injury to the brain, such as hemiplegia, paraphasia, alteration of character and loss of mental ability. The latter symptoms are to my mind such dangerous and not infrequent possibilities of gasserectomy that I believe the operation should never be performed for the relief of chronic trigeminal neuralgia until alcohol injection has been fully tried by an experienced man. The permanence of the relief from pain in the majority of (not all) cases of gasserectomy is insufficient to weigh against the necessity for reinjection with alcohol that is likely to be necessary at intervals of one to four or five years.

Lastly, let me reiterate the necessity of taking one's time, with absence of all hurry, in performing the injections. Trial and test is, I am certain, the only safe method, and I am never satisfied until I have produced deep anesthesia, for then I know, if my diagnosis of chronic trigeminal neuralgia has been correct, that the patient will have many months' freedom, and in quite a large number, three, four and five or even more years' immunity from pain.

56 Wimpole Street, W.

ABSTRACT OF DISCUSSION

Dr. Charles R. Ball, St. Paul: I first obtained inspiration for making these injections of alcohol in facial neuralgia about six years ago from Dr. Patrick. The irregularity in the distribution of the branches of the fifth I think often accounts for the difficulty in making some injections. I tried repeatedly in one case to inject the third branch but always failed. One day while attempting to inject the second branch the patient complained of severe pain in the area supplied by the third branch. I immediately injected alcohol at this point and secured a perfect anesthesia in the part supplied by this branch, with complete relief of the pain. The danger in making this injection would not seem very great. In an experience with hundreds of injections, I have had only two accidents which, at the time, seemed apparently serious but eventually came out all right. In a severe and intractable tic douloureaux involving all three branches of the fifth nerve, I was attempting to inject the third branch when I noticed the development of a facial paralysis on the side I was injecting. My patient, who was past 80, became unconscious, went into a state of collapse and for a period of half an hour it seemed as though she might die on the table. My first thought was that she had had a stroke of paralysis, but afterwards it became clear that I had passed the needle up into the foramen ovale and injected the ganglion. Some of the alcohol had infiltrated back as far as the seventh nerve and induced the facial paralysis. After the patient returned to consciousness I found that a complete anesthesia involved all three branches of the fifth nerve. In another case, in attempting to inject the second branch, I got a severe hemorrhage. The eye, on the same side, began to come forward, just as though some unforeseen and mysterious force were pushing it out of the head. The pupil became dilated and the patient for an hour was unable even to see light. This patient also recovered without any serious injury to the sight. In my experience, Dr. Harris' method of injecting the gasserian ganglion from the point of entrance for the injection of the third branch is more practical and simpler than the method proposed by Härtel. In repeated trials on the cadaver I have been able to place the needle in a better location in the foramen ovale from the point recommended by Dr. Harris than the one proposed by Dr. Härtel. In cadaver injections, with Dr. Härtel's method, the chief difficulty seemed to be in entering the foramen at one side and causing the needle, instead of penetrating nerve tissues, to go through the dense fibrous tissue which lines the bony borders of the foramen. In this location the fibrous tissue makes a complete barrier, and absolutely prevents the alcohol from reaching the nerve or ganglion.

Dr. Peter Bassoe, Chicago: Dr. Harris rightly says that the injection method should not be used when the lesion causing the neuralgia is known to be proximal to the point at which the nerve can be injected. I believe there is one exception to this rule, however, namely, herpetic neuralgia. I saw immediate relief follow injection of the supraorbital nerve in a case of frontal pain which had existed for several months following a severe herpes with corneal involvement. I presume that the explanation for the relief must be that such a large portion of the neuron was peripheral to the point of injection that the entire neuron became impaired. In other words, we may assume that a retrograde degeneration took place. Dr. Harris' remarks concerning supraorbital pain at regular hours as being due to malaria, influenza, etc., are of interest. For the benefit of those who have little experience in neuralgia cases, it might be well to state that probably most pain of that kind is due to frontal sinus disease. I have frequently had sent to me for treatment by alcohol injection cases of frontal sinusitis and pressure within the nose. Dr. Harris said he has seen no good result from injecting the mental foramen. In one case, which happens to be the last one in which I injected alcohol, it seemed to be of value. It was a case of neuralgia of the middle branch, but pain in the middle branch area could be started by rubbing the lower lip. There was no pain in the distribution of the inferior division but after successful injection of the middle branch, rubbing the lower lip still would start pain in the middle branch area. I injected the mental foramen, producing analgesia of the lower lip, and pain could no longer be started by rubbing the lip. What is Dr. Harris' opinion concerning the rôle of previous peripheral operations in making the alcohol injections less efficacious? French observers, particularly Sicard, have claimed that alcohol injections are less successful in cases in which nerve resections have been made. I have sometimes had trouble on account of the foramina having been plugged with amalgam, screws, or other foreign bodies, and even after deep nerve injections it was necessary to remove these foreign bodies to get relief.

Dr. C. D. Camp, Ann Arbor, Mich: Dr. Harris is the pioneer of the injection of the gasserian ganglion with alcohol through the foramen ovale. I read Dr. Harris' first paper shortly after it was published and, after some experiments on a cadaver, I concluded that the operation was an entirely feasible one. I have made three successful injections of the ganglion, using the Harris technic. The details of these cases I published in the *Medical Record*, July 20, 1914. In all of these cases the neuralgia was relieved. My experience differs from that of Dr. Harris with respect to the sense of taste. In all of my cases the sense of taste was preserved in the anterior two-thirds of the tongue, although there was complete analgesia in this region. There were no cases of keratitis in this series. Of course, the usual precautions were taken to prevent any foreign matter from irritating the cornea. The injection of the gasserian ganglion is quite a different proposition from the injection of the peripheral divisions of the fifth cranial nerve, but it is hoped that the destruction of the ganglion will not be followed by recurrence of the neuralgia.

Dr. George A. Moleen, Denver: I have seen most of the neuralgias in the clinics and in the practices of other physicians. I find in about 1,500 case records not over a half dozen trifacial neuralgias. Among those there are probably four or five of what might be termed postmalarial, supraorbital neuralgias that were distinctly amenable to appropriate treatment. I question whether or not the altitude may have something to do with determining the susceptibility of the trifacial nerve. I do not believe that in the entire Rocky Mountain region we have anything like the percentage of cases reported in any one neurologic clinic at sea level. Does Dr. Harris confine his injections, even in the milder cases, to alcohol, or has he, in the case of specific neuralgia, found any relief from the use of salt solution? We see in Colorado quite a number of peripheral facial paralyses, and I have noted, even with careful testing, that taste is not only abolished in the anterior two-thirds of the tongue on the same side in these cases, but also on both sides. Whether that is due to disturbance in the attention, faulty technic, or what not, I am not able to say, but it may account for the loss of taste discovered after these injections. I am quite certain that taste was lost on both sides, having been prompted to test the other side after having found it absent in the ipsolateral side.

Dr. Wilfred Harris, London, England: Answering Dr. Ball, who referred to injection of the seventh nerve with alcohol, I would say that this was the first use to which injection of this agent was put originally by Schlösser in order to relieve the painless form of facial spasm. These unilateral facial spasms are not common, and they are rarely so severe as to cause total paralysis of the face. As to using alcohol in these cases, I have injected this agent a few times, but not recently. I was interested in the first case cited by Dr. Ball, in which in injecting the ganglion through the foramen ovale, he produced facial paralysis and collapse. I have recently seen a somewhat similar condition in a hospital patient aged 60. Total anesthesia developed over the whole fifth nerve area. The woman began to slip over and fall toward me as I was working on the left side, she had nystagmus toward the opposite side, and her face became paralyzed on the side on which I was working. For a moment I thought, Have I possibly injected the seventh nerve peripherally? It was quite plain, however, that I had not done that. When I had finished I investigated more carefully. There was more or less facial palsy, and, a point Dr. Ball did not refer to, she had total nerve deafness as well as this facial palsy. She had nystagmus to the opposite side. In two days there was no trace of the trouble which had developed so acutely and which alarmed me much for a moment. I have never seen any such severe hemorrhage as occurred in the second case mentioned by Dr. Ball, but have read records of severe hemorrhages having occurred; and I am certain that the moment any such sign of hematoma develops the only thing to do is to withdraw the needle and hold on tight, using firm pressure for ten minutes. If this is done the hemorrhage will cease. Dr. Bassoe referred to injection in postherpetic neuralgia. I do not believe this is advisable treatment in those cases. The lesion is proximal to the point where the injection can be placed. Theoretically it cannot be defended, and in practice no good results obtained; on the contrary the patient is made worse. The majority of persons have had that experience in this trouble, and it has been certainly my experience with alcohol injections in those cases. Dr. Bassoe says his patient recovered. Some of these patients do recover spontaneously. I do not find that scars make any difference in the result in peripheral operations, if they do not interfere with getting the needle in the right place. Dr. Cramp referred to anesthesia of the drum membrane. That is a striking symptom. You can touch the tympanic membrane without the patient flinching or objecting, but there is not complete anesthesia because several nerves supply that part. The question as to preservation of taste will, I think, never be settled, but there is no getting away from the results. In about seventy instances I have seen total loss of taste in two-thirds of the tongue on the same side on which the patient still recognized taste acutely on the opposite side; but now and again one comes across a case in which taste does remain unimpaired on the same side, in spite of anesthesia to pain and touch.

THE RELATION OF PHYSICAL THERAPY TO THE HOSPITAL PATIENT FROM THE POINT OF VIEW OF THE INTERNIST *

WALTER L. BIERRING, M.D.
DES MOINES, IOWA

The purpose of this paper is to emphasize the rôle of physical therapy in its relation to patients admitted into a general hospital.

It seems proper at this time to indicate wherein the general hospital more completely realizes what hospitals are expected to accomplish. In its physical plant, well-organized medical, and efficient nursing staff, it should represent in highest efficiency the essential coordinating factors for conserving the patient's best welfare.

The primary function of the hospital is to cure disease, and to relieve suffering. A hospital which fails to cure a patient, who is theoretically curable, fails to that extent to perform its proper function.

The subject of hospital care and treatment is the patient and not the disease, so that the hospital should include in its physical equipment and in its medical organization the means of dealing with any pathologic condition, or complication of disease, expected or unexpected, in any individual patient.

The general hospital exemplifies the spirit of modern medicine; consequently, the hospital patient fares best in it, and it is better for the education of the medical student and medical intern to be in the atmosphere of a general hospital.

It may be further said that the establishment of real general hospitals will quicken medical research and investigation, will place adequately equipped laboratories at the disposal of clinicians generally, will facilitate sound medical teaching, will insure a more adequate training of nurses, and will tend to standardize the general efficiency of hospital work.

No hospital can give satisfactory service in all emergencies which does not represent in its clinical and laboratory organization, and in its therapeutic equipment, all that modern medicine is able to contribute of technical skill and expert knowledge to the investigation and treatment of disease.

Physical therapeutic methods have now become an essential part of the treatment of patients in any general hospital. There can be no sympathy with the employment of physical therapy purely for the psychic effect on the patient, for when we consider physical therapy, we are not thinking in terms of psychology, because for such purposes the ingenious physician will find or indicate his own medium.

There must be a definite purpose in the use of all physical agents, as in the application of any other therapeutic procedure.

It is of particular interest to note that the average patient admitted to the general hospital presents a distinct type, in so far as he or she is often in the terminal stage of a vicious cycle (of a nutritive disturbance), whether it be an example of cardiovascular renal disorder, of chronic nephritis, of diabetes, visceroptosis or neurasthenia, it seems so often but an expression of a chronic nutritional disorder. This means usually that an attempt must be made to improve nutrition and to reestablish function, and it will tax the best efforts often to bring about a circulatory, nutritive, or psychical balance, so that even though a cure may not be possible, subsequent living will be more comfortable.

It is but rarely in this class of patients that a special surgical procedure, or definite medical treatment, is the essential requirement; as a rule a more prolonged stay in the hospital is necessary, and this permits a better cooperation of diet regulation and other forms of therapeutic procedure with physical therapy so as to promise the greatest degree of improvement.

It is not the purpose of this paper to consider in detail the different physical methods of treatment, and in fact only a very small proportion of patients coming into the hospital will require the employment of more than one or two, yet it is highly necessary that hospitals should be so equipped as to be able to respond to the demands that any condition may require. The best expressions of physical therapy are not always the most elaborate and costly, and often quite as valuable work can be done with improvised apparatus, accompanied by good sense.

HYDROTHERAPY

Man from his advent has daily experienced the beneficent action of water. As symbolism has characterized all primitive mental expression, so it has been

---

* Read before the Section on Hospitals at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

but natural that man used water not merely when ministering to his bodily cleanliness, but also as an effort to convey ideas of moral purification. In this way hydrotherapy developed under sacred auspices, and the use of water as a healing agent acquired the dignity of a religious ceremony. Certain waters in the old world gained more or less of a reputation for special efficacy, and to the testimonials of their wonderful cures eminent physicians have at times added their endorsement.

Aside from the mysticism that has enshrouded water as a therapeutic agent, it has always been regarded as a most valuable adjunct in the treatment of various diseased conditions.

There has been a common error to restrict the term "hydrotherapy" to the remedial use of cold water alone, when it should include the application of water in any form, from the solid and fluid to vapor; from ice to steam, internally and externally; again hot water is as important a hydriatic agent as is cold water.

The mineral constituents of water do not often add to the effects produced, since the latter are often the result of the judicious adaptation of the mechanical and thermic influence of water alone.

It is needless to emphasize that every hospital should afford ample material for the thorough mastery of the Brand bath in the treatment of typhoid fever.

The benefit of the Brand bath is not confined to the reduction of temperature alone, and the idea that high temperature is the chief determining cause of fatality in typhoid fever must be abandoned, for it seems justifiable that the failure of heart power is less an effect of high temperature than of other concomitant conditions. The lessened perspiration, the renal disorders, disturbed sensorium and digestive disturbances are all favorably influenced by the Brand bath when properly applied.

In all the pyrexias of infants and young children the warm bath and pack is an equally potent means for reducing temperature, besides assuaging pain and relieving nervous debility, without materially interfering with any of the functions. For this purpose there is no remedial agent which can compare with a full bath of 98 degrees, reduced perhaps to 90 degrees for eight to ten minutes, combined with gentle friction.

Hot baths constitute an important factor in the treatment of every case of cerebrospinal fever, in exerting a modifying influence on symptoms and the course of the disease. In accordance with the contributions of Rosenow, the *Streptococcus rheumaticus* is favored in its development by cold surroundings and inhibited by warm, so that the application of the warm pack to affected joints in acute rheumatic fever not only relieves pain, but may likewise have an inhibitive action on the infective process.

The prolonged warm bath has attained a special place in dermatologic conditions; promoted by Hebra it has proved valuable in extensive burns, while in skin affections like pemphigus foliaceus, it tends to relieve pain, mitigates the fever and restores sleep and digestive functions.

The continuous bath is likewise useful in different forms of cerebral irritability, such as acute delirum and mania; in the bedsores of tabes, myelitis, cerebral and spinal tumor, the advantages of the water-bed will be best appreciated by those who have treated such cases without it.

The value of the warm bath, hot pack and different forms of sweating procedures in the different types of nephritis is generally recognized. In recent years the significance of albuminuria as a manifestation in nephritis has lost some of its import, while more emphasis is being placed on renal insufficiency in the elimination of nitrogen, chlorids and water. The result of this more practical and broader view has been a more intelligent regulation of the hygienic environment of the patient and his diet.

Directly connected with the application of hot water is the hot-air bath in enhancing the reactive capacity of patients subjected to hydriatic procedures.

Experimental and clinical observation reveal a pronounced and often considerable increase in diuresis and elimination of all products of tissue change on the bath days. There is often a decided relief from retention symptoms, the hypertension is modified, headache disappears and gradually the nutritive as well as the circulatory balance can be reestablished.

There is often no more effective measure of relieving the distressing headache of hypertension than the evening hot foot-bath.

We all know that dry heat applied as sand bags, sacks of hot salt and hot bran affords decided relief to various forms of neuralgia, myalgia or other localized pain.

Dry heat of high temperature is not employed for any considerable number of purposes, but a lesser degree of heat is employed in what is termed the baking process used for neuritis, myalgia and the different forms of chronic arthritis. The only drawback to its more general use has been the expense of the necessary apparatus, but it is to be hoped that before long more simple equipment can be obtained at a lesser outlay.

MASSAGE AND EXERCISES: MECHANOTHERAPY

It is only within the past thirty years that massage has been employed to any great extent in this country, and it is largely due to Dr. S. Weir Mitchell in his employment of it in his famous rest cure, that it has begun to receive serious consideration.

At the present time it is a well-recognized therapeutic measure, and has proved valuable not only in combating certain nutritional disorders, but also in surgical conditions. When employed in connection with systematic exercise it is of value in various conditions coming properly in the field of the orthopedist. A practical knowledge of anatomy and physiology, besides the necessary manipulative skill, is highly essential in its application, so that it requires a proper training of the nursing staff or employment of special masseurs by the hospital to obtain the best results.

Massage exercises certain physiologic effects, and on these its application in disease conditions is based. It has a favorable influence on the circulatory apparatus in promoting increased activity, reflex stimulation of the heart, and slight temporary rise of blood-pressure, and aids respiration by lengthening the excursions of the diaphragm.

There is probably no branch of medicine which offers so large a field to massage, or in which more satisfactory results have been obtained, than in the treatment of nervous disorders. Its usefulness may be considered under two heads, one being as a general tonic and stimulant to muscular tissue and the other as a sedative agent.

In the particular individual often referred to as the Stiller type, or habitus asthenicus, in which visceroptosis or splanchnoptosis is the distinctive feature, systematic massage seems often the only remedial measure that promises any relief. A combination of general with abdominal massage exerts a favorable influence on the general state of myasthenia that exists, and thus relieves the distressing abdominal symptoms which form such a prominent feature of this condition.

Various conditions are specially responsive to a judicious combination of massage and gymnastic exercises; among these should be mentioned the different occupation neuroses, and conditions presenting atrophy or muscular spasm occurring in cerebral lesions affecting the motor areas or its cerebral and spinal tracts.

Massage constitutes an important part of the palliative treatment of tabes, and the reeducational movements in ataxia as formulated by Fraenkel have been employed with gratifying success.

In this connection reference should be made to the use of carbonated baths in heart disease, as represented by the Nauheim baths, combined with the passive resistance exercises of the Schott method, or the graduated exercises of Oertel.

In discussing the value of baths and exercise on heart diseases, consideration must be given to what is expected of the treatment. In all methods of cardiac therapeutics, there are three main purposes, namely, those which spare and soothe the heart, those which solicit or revive it and those which repair it.

Rest is an example of the first, digitalis of the second, while baths and exercises belong to the rebuilding kind, and if our demands here overtax the remnant of cardiac capacity, we shall exhaust the heart or overthrow it. We are aiming to make new heart muscle, and to appreciate this possibility in all cases is a task of no little difficulty, so that the application of the Nauheim method should always be made with careful discrimination.

In many disease conditions a systematic combination of several forms of physical therapy is necessary to promote the best result.

There are other forms of physical agents as represented by light, electricity, radio-active substances, and the Roentgen ray, which are effective in certain conditions, yet many of the virtues ascribed to them are more or less speculative, and a complete equipment in all these lines in a general hospital in the light of present knowledge is not absolutely required.

Physical therapy should always be regarded as an adjunct in the therapeutic measures for the relief of disease conditions, and therein lies its main argument for a close relation with a general hospital, since here only is afforded a proper cooperation of a well-organized staff to promote the best results.

The establishment of special institutes for physical therapy is unfortunate, since it offers the same objection as the specialist in relation to general medicine, in that it tends to a restricted point of view as to disease conditions, and often leads to an exaggerated conception of the therapeutic virtues of some particular form of physical therapy.

There can be no question that as physical therapy loses its proper relation to the general hospital, it favors the establishment of separate sects, of pathies based on the use of one or other physical means of therapy. These are distinctly undesirable, not alone in the interest of scientific medicine, but also for the welfare of the unfortunate patient.

Equitable Building.

SIX YEARS' EXPERIENCES AT THE MEDICOMECHANICAL DEPARTMENT OF THE MASSACHUSETTS GENERAL HOSPITAL *

C. HERMANN BUCHOLZ, M.D.
BOSTON

The medicomechanical department of the Massachusetts General Hospital was founded ten years ago by the gift of sixty-three Zander apparatus from a benevolent lady. For the first three years it was in charge of Dr. Max Boehm, now in Berlin. For the last six years the department has been conducted by me. The accompanying tabulation gives an idea of the number of patients treated and the amount of work done during these six years. The steady growth of the number of new patients shows how the department has become more and more an important factor of the hospital; particularly the surgical and medical departments use it to a considerable and steadily growing extent. These numbers would still be larger, if the nerve room had not enlarged its own department for massage and exercise.

CASES TREATED AT THE MEDICOMECHANICAL DEPARTMENT FROM APRIL, 1908, TO MARCH, 1914

Fracture of humerus, scapula, clavicle	182
Fracture of elbow	227
Fracture of forearm and hand	161
Colles fracture	305
Fracture of spine, ribs, pelvis	19
Fracture of thigh and patella	100
Fracture of leg, ankle, foot	226
Fracture with delayed union	38
Total fracture	1,258
Dislocations	128
Stiff joints (except fingers)	180
Stiff hands and fingers	174
Arthroplasties	9
Contractures and deformities	118
Contusions and sprains	166
Subdeltoid bursitis, a. o. bursitis	331
Myositis	12
Infectious arthritis	370
Septic hand	212
Gonorrheic arthritis	86
Villous arthritis and arthritis deformans	120
Total arthritis	788
Sacro-iliac and back strain	208
Weak back and faulty posture	197
Lateral curvature	276
Total back cases	681
Feet	265
Neurosis	94
Hemiplegia	112
Infantile paralysis	131
Other paralysis	110
Other nerve diseases	100
Total nerve diseases	547
Diseases of the circulatory system	33
Diseases of the respiratory system	16
Diseases of the digestive system	38
Other internal diseases, including debility and convalescence	60
Total internal diseases	147
Miscellaneous	100
Grand total	4,904

The medicomechanical department consists of a large room with the Zander apparatus, a balcony for the special corrective work, two small rooms for massage and manual exercise as well as baking, and an office for examination and manual treatment. As to the distribution of room, the apparatus part of the work is markedly favored, a condition which is not in accordance with the needs of a general hospital such as ours, and, indeed, in the plans for a new building much more room has been provided for the manual work. Since I frequently meet in practice erroneous ideas of patients as well as of physicians in regard to the value of apparatus, I shall explain the comparative value of manual and apparatus treatment. A differentiation as to the massage and exercise and as to the local and the general effect of the treatment must be made. As to the massage, it cannot be doubted that the manual work holds the first place. Mechanical massage can be only a very poor substitute, except vibration and, to a certain extent, tapotement. The other manipulations, effleurage, kneading and friction, demand a thorough training and a full understanding of what we have under our fingers. Massage properly done requires a good deal of brainwork.

---

* Read before the Section on Hospitals at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

Machines are a good compensation for the exercise in many ways, but they are by no means a full substitute, nor are they, in my opinion, indispensable in obtaining the local effect. Most of our surgical and orthopedic patients have to begin their treatment with the manual methods of passive and active, assistive and resistive exercise, and become ready for apparatus treatment only when they have gathered sufficient strength to control the apparatus. In those cases the greatest value of the apparatus is that they spare the time of our assistants. On many days sixty, eighty and even up to 100 patients are to be treated in from three to four hours. The average time of one treatment being considered as twenty minutes, which is rather short, we would need at least seven or eight trained assistants, a heavy burden for a charity hospital. The apparatus do not necessarily require a trained attendant, though of course an intelligent and expert supervision is desirable.

For certain local effects apparatus are of particular value, as in furnishing symmetrical stimulations in many paralytic and other nervous conditions. And the so-called promotive exercises in which the moving power is furnished by a turning wheel, a pendulum or an electric motor are of extreme value and cannot be very well carried out by manual exercise.

For the general effect on the circulatory, respiratory, digestive and nervous systems and on the general metabolism the apparatus are of great value and have a decided preference over the manual treatment. It should not be said that we necessarily depend on apparatus, and patients living too far or being too sick to go to the outpatient department could not have proper exercise treatment. Nor would I like to give you the impression that we can do everything with the apparatus. Also in this class of cases the manual exercise has its definite place and cannot be missed.

In close connection with the medicomechanical department is a hydrotherapeutic department in my charge. These departments cooperate freely in that many patients get both hydrotherapeutic application and treatment with Zander apparatus on the same day or on alternating days. Of Bier's methods only the baking is used to a large extent. Bier's congestion by a rubber bandage has been of much value in treating ward patients, but is a method far too difficult of application and too dangerous to be satisfactory in outpatient cases.

The various methods of electrical treatment which represent another branch of physical therapeutics are distributed among the Roentgen-ray and nerve departments. If necessary patients are treated at the medicomechanical and any one of the other departments on the same or alternating days.

The Zander room is a subsidary department in that outpatients have to belong primarily to one of the regular clinics and are sent to the Zander room for treatment. Thus the medical man, the surgeon, the orthopedist or the nerve man makes the indication as to the treatment in the medicomechanical or hydrotherapeutic department. He also may suggest the form of treatment which he considers best, or he may leave this to the surgeon in charge. But it must be insisted that the director of such a department has absolutely free hand to decide as to the form and amount of treatment, as well as to refuse treatment if he considers it not a suitable case. Frequent consultations with the other departments favor a mutual understanding in this direction.

At present the surgeon in charge of the medicomechanical department is holding a position as orthopedic surgeon to the outpatients, while his assistant holds a place as assistant at the same department. This personal union of the orthopedic department and the department for physical therapeutics is in my opinion of greatest value not only to the orthopedic cases, but also for the whole hospital, and becomes more and more so with the growing field of orthopedic work. The value of this union is also acknowledged by the university in the appointment of the surgeon in charge as assistant in orthopedics and physical therapeutics at the Harvard Graduate School of Medicine. We meet the same union in many German university clinics and hospitals as well as in the field of the most important orthopedic journals abroad.

TREATMENT OF STIFF JOINTS BY MASSAGE AND EXERCISE

Before we consider the various lesions which we have to treat, a few words should be said about the treatment of stiff joints in general by massage and exercise. Massage has the purpose to stimulate the circulation and nutrition of the affected limb, to hasten the absorption of edema and waste matters about the joints, within the muscles, tendon-sheaths, bursae, etc., to loosen adhesions between the various layers, to favor the function of the skin. Most useful for these purposes are the long stroking over the muscles, the kneading and pressing of the fleshy parts and the friction of the smaller parts. With any irritation or tenderness still present the friction should be done with a great deal of ease and should not cause any pain. The kneading of the muscles should generally cause an agreeable feeling of relief; it is particularly indicated after the exercises.

Far more important than the massage is the exercise. To be brief, exercise consists of passive and active movement in its infinite varieties. In the treatment of stiff joints the active movement is of much greater value than the passive. This seems a plain, simple statement, hardly worth mentioning, but daily experience shows me that this great principle of functional therapy is not sufficiently understood. Many patients who are sent to the department for the treatment of stiff joints following fractures or other lesions bring a note from their surgeon prescribing passive exercise. Furthermore, we sometimes have the following experience: A patient with a stiff joint being treated at our department reports to the surgical department. The surgeon, not satisfied with the speed of the progress, gives a few more or less forced passive movements which in almost every case cause an irritation sufficient to interrupt the so far steady progress. Occasionally I have had a chance to prove this observation by exact measurements. Also among so-called trained masseurs the passive movement enjoys a better reputation in the treatment of stiff joints than it deserves. About every one of them who has come to work with us has had to learn this anew.

A joint is not a door hinge, but a complicated and extremely sensitive living mechanism. Its proper function depends on many conditions, inside and outside. A rational therapy should be preceded by a thorough examination clinically and by the Roentgen ray. The examination should find out the condition of the articular cartilage, the thickening of the capsule, any relaxation or retraction of ligaments, adhesions of tendons and tendon sheaths, retraction of the muscles and their perimysium and everything else which might come in question in the individual case. On this examination depends not only the prognosis, but also to some extent the therapy, although the functional principle holds good for all. A type of cases very frequently seen at our department is that which I have described as the traumatic hand, a change likely to come on after injuries of any part of the arm and shoulder. The clinical features of the traumatic hand are, to be brief, marked thickening and tightening of the soft tissues of the fingers, especially around the interphalangeal joints, and in the roentgenogram a marked atrophy of the bony structures. The function of such a hand is always more or less restricted, often the hand is very badly crippled. It is evident that the limitation of function is caused by a severe alteration of the tissues which may be most precisely termed as lack of elasticity. Whether or not normal conditions will be restricted depends on the amount of alteration which has taken place, and on the recuperative power of the patient's tissues in general. Our therapy must do whatever possible to aid Nature's attempt in restoring proper conditions. First of all we should try to improve the circulation and by that the whole nutrition and metabolism of the limb; our best means are baking, massage and especially functional stimulation. The passive exercise if done alone neglects this most valuable factor. It is liable to cause irritation and inflammation, resulting perhaps increased stiffness, as we have frequently seen.

One might maintain that such active movement may be done by the patient himself and he would not need any treatment for this purpose. This is perfectly true, and I think it is much better to leave such a patient alone than to push him through the misery of a poorly managed treatment which might do him more harm than good. Nature is not likely to cause so much damage as a masseur's hand might do, if it is not guided by a thorough understanding of physiologic and pathologic laws. But experience shows that the proper application of assistive and resistive exercise with all the wise suggestions of the Swedish system as to measuring and localizing the active movement can help the patient along in a marvelous way.

Another point of importance in our work is the educative effect as well as the influence on the mind of the patient. I have found many times what an encouraging and stimulating effect it has when you teach your patients how to do things which their crippled joints have not accomplished before.

FRACTURES AND DISLOCATIONS

Relatively the greatest number of our cases consists of fractures. Treatment of fractures is composed of two parts, the proper healing of the bones and the restoration of the function, or, as we may briefly say, the anatomic and the functional parts. In the clinical lectures as well as in most text-books the functional side of the question is considerably neglected. The impression which I have from my experiences may be somewhat pessimistic, since I usually see the worst cases, but even so, I venture to say that much fault will be seen in the end-result of fractures, unless the functional treatment meets that consideration which it deserves.

This is particularly true of the fractures involving or near to joints and it is in this great group of cases that the functional treatment of Lucas-Championnière has had its best results. The idea of this great surgeon has been to follow Nature's example. Now what do we do with a fractured limb? We put it in a plaster cast or on a splint for at least that amount of time which is generally required for the union of the bones and often much longer. Then when we remove the splints we see in a great many cases the involved joint stiff; often joints in the neighborhood and not rarely all joints of that extremity more or less affected, the muscles and all the tissues including the bones much atrophied, the limb useless. A damage is seen which at least frequently is not the direct result of the injury, but is more or less brought about by the treatment. When such a case is referred from the surgical to the medicomechanical department for after-treatment the surgeon should be conscious that he carries the responsibility for the definite outcome.

The separation of the anatomic and the functional part has its practical value, but it is liable to bring up a certain danger. Kocher's word that the function of the limb depends on the good position of the bones is right in only one sense and only to a certain degree. A bad position is liable to disturb the function, but it is not the only, and frequently it is not the main cause of stiffness. On the other hand, that good position may be accompanied by a poor function can be proved by many examples from our records. It is not the place here to discuss the possibilities of carrying out the functional treatment of fresh fractures in a general way. Its principles are sound, though we do not mean to adopt it so far as to leave off fixation even in fractures of the diaphyses. It is often the exaggeration of an otherwise rational treatment which has delayed its general use.

Among the 1,258 fractures there are thirty-eight with delayed union. Many of these patients had been treated a long time before they were sent to our department. In some of them the conditions urged operative interference, but in the majority the treatment with massage and exercise has proved very satisfactory in that bony union was obtained during a reasonable time, while at the same time the function was more or less restored. Reports of a number of these cases were published in 1909. Of the later cases one deserves particular notice:

A man aged 25 years, with a 9-month-old compound fracture of the humerus between the middle and lower one-third. The fragments were very loose and there was a sinus over the point of the fracture. All joints of the left arm and hand were greatly limited in motion. When the patient was referred to me for consultation as to the advisability of an operation I hesitated because of the sinus and because I was afraid of further delay of the functional cure by fixation after the operation. I therefore asked to refer the patient to the medicomechanical department where he was treated by massage and exercise. After four to five weeks the fragments were practically solid and the sinus was closed. The hand and fingers and to some extent the shoulders had been very much improved in motion and only the elbow did not make good progress. The patient has been under treatment for a long time and his arm has been strong and useful except for the elbow, which showed only about 30 degrees of motion. Had that form of treatment been started seven or eight months earlier, we might have obtained a full functional cure within a much shorter time.

The functional principles in the treatment of dislocations do not differ very much from those of fractures. In the uncomplicated cases functional treatment may be started very early. There is no reason to hold such joints in casts or splints for four or six weeks as we see it done so frequently.

A few words need to be said about the dislocation of the elbow. In these cases there is a certain danger of ossification along the tendon of the brachial muscle. Since the injured periosteum is readily subject of extravagant production of bone tissue, any irritation must be carefully avoided. This is also necessary in the treatment of fractures near joints where an abundant formation of callus may do much harm.

STIFF JOINTS

Under the head of stiff joints are classified joints affected by operations, wounds, burns, etc. They do not need any separate discussion, but a word may be said about the time when it is wise, in my opinion, to begin the after-treatment in cases of suture of tendons of the hand. Most of those cases had been splinted for four to six weeks after the operation. When they came to us the hand was stiff and often required a treatment of many months to make it limber again. It seems to me that ten or twelve days after the operation gentle exercise can safely be started provided the wound is well healed.

The same mistake of too long a fixation is invariably made after the radical operation of Dupuytren's contracture. Splinting such a case for four or five weeks, as I have frequently seen, without giving the patient at least a chance to move his fingers is dangerous and has led in some of our cases to a prolonged stiffness, some having never well recovered. This is all the more dangerous, because the patients are usually of an advanced age. In a case like that I apply a splint for two weeks constantly and for another month over night and begin with gentle active and passive movements on the third or fourth day after the operation.

The same experience I have had with tendon transplantations. Several patients came for after-treatment as much as three and four months after the operation. During that time the transplanted tendon had become firmly embedded in scar tissue and the hope of obtaining any active function of it was entirely gone. There is no reason why the exercise treatment in such a case should not be started three or four weeks after the operation at a time when the tendon is still movable. Then we need the functional stimulus for the formation of a new tendon sheath which is necessary for the definite function. About the other affections in this column everything necessary for the understanding of the treatment is included in the previous paragraphs and in that on arthritis.

ARTHRITIS

The value of physical therapy in the treatment of the various forms of arthritis is generally recognized. We may distinguish an effect as to the actual cure of the disease and as to the restoration of the function of the affected joints. In regard to the infectious arthritis in its various manifestations we maintain the modern point of view in that it is our first duty to study each case in order to find the focus of the disease. We know that with the elimination of such a focus the case may clear up according to the amount of pathologic changes. The place of physical therapy, therefore, in regard to this indication must be a secondary one, but nevertheless its tonic effect is frequently of great value in strengthening the patient's lowered resistance against the known or unknown enemy.

With any acute inflammation still present the affected joints must be kept quiet, but gentle massage applied to the muscles centralward acts often decidedly pain lessening and relieving. Baking is not advisable in the acute stage; it may irritate the joint and aggravate inflammation. Bier's congestion treatment has given us sometimes excellent results. We have had a number of cases with infectious arthritis of the gonorrheic type and others in which the patient had not slept for several nights because of the intense pain and the application of the elastic bandage stopped the pain almost immediately. The technic of this method is perfectly simple, but in my experience, frequently misunderstood.

The most difficult question perhaps is how soon to begin with the exercise treatment in order to restore the limited function. Doubtless many cases clear up without any particular after-treatment, but there are others, probably of the fibrinous type, in which a marked degree of stiffness may remain, when fixation is sustained for too long a time, and sufficiently gentle exercise treatment can certainly shorten the time of disabling very much. When to begin in such cases must depend on the experience of the physician and on his technic to carry out such a treatment. It needs a well-trained hand to treat such joints effectively and carefully at the same time.

The treatment of arthritis deformans in its various manifestations as hypertrophic and atrophic arthritis is a difficult and discouraging chapter of medical therapy, but of all that we can do for such patients the physical therapy occupies a prominent place. Hydrotherapy, thermotherapy and balneotherapy, massage and gentle exercise have given us at times encouraging results although we usually get our patients with anatomic alterations so far advanced that anything like a cure is out of the question. We have had quite a number of patients at the Zander department who showed a distinct improvement in mobility and strength. Even in old neglected cases it is worth while to make a trial, provided the patient can furnish the necessary energy and endurance.

BACK CASES

With the change which the explanation of sciatica and lumbago has undergone in recent years, following the well-known investigation of Goldthwait and others, the treatment of these widespread conditions has become more rational than before. A better understanding has led to a clearer application of an etiologic therapy, instead of the purely symptomatic treatment which heretofore has largely been used. A revolution in ideas like that, however, often causes neglect of methods which have deserved their merits from experience. This has been the case in our clinic in regard to the application of physical therapy, especially massage and exercise. The number of cases of this type referred to our department is very small in relation to the large material treated at the outpatient department. Such neglect is very much to be regretted, because appropriate application of physical therapy has sometimes given us very satisfactory results even in old cases in which all orthopedic measures have in vain been exhausted. However, we recognize the difficulty of thoroughly carrying out this treatment in outpatients. These results are not surprising in the light of the modern theories. We have learned that in many cases of sciatica and lumbago the pain is referred from lesions of the sacro-iliac, lumbar and lumbosacral regions which may be intra-articular or extra-articular. When we consider the effect of rational physical therapy in many other articular or periarticular affections elsewhere in the body, we cannot be surprised to meet similar effects in the treatment of this class of cases.

Next are to be considered the cases with round shoulders, faulty posture and lateral curvature. It might be of interest to report briefly the development which the treatment of these cases has had in our clinic during the last six years. When I took charge of the department it had been the custom to treat these patients almost solely with Zander apparatus. Very soon I added to this form of treatment special exercises, which were directed by me and given by my assistant. Since the number of patients steadily increased, an extra class was formed under a teacher trained in orthopedic corrective gymnastics. This class has now a very large frequency. One of the Boston Normal Schools for physical education furnishes us with volunteer assistants. The idea of the treatment is the individual training and education. Zander apparatus are in use only in addition to the individual exercise. A systematic record as to the frequency of visits, weight, height and the kinds of exercises used, and in the most severe cases, stereoscopic photographs taken after the manner described by Osgood and myself form a useful material for scientific observation. The exercises are all given with the patients' back exposed, thus allowing a good control of their various movements and postures.

FOOT CASES

Of the 265 foot cases at least 95 per cent. belong to the type of weak pronated feet; in about 20 per cent. a distinct peroneal spasm was present. Not counted in this rubric are the traumatic flat feet following fractures or sprains, or those foot troubles which are caused by infectious arthritis, or the paralytic deformities of the foot. If all those cases were included the total number would be at least twice as large. As to the indication of exercise treatment in the typical flat foot, I cannot share that enthusiasm which is shown by some authors. I do not believe that exercise treatment is ever able to cure a flat foot, but it has its definite place as an educative factor. It should be carried out as individual training in a similar way as in the treatment of lateral curvature. The patient should learn how to use his feet properly. If you accomplish so much, you can materially compensate and assist the usual orthopedic treatment.

Pain is not always a contra-indication for exercise treatment. We have had a number of patients with painful feet who for some reason had no other treatment besides and were relieved of their pain by massage and exercise while the strength and balance of their feet was at the same time improved. Occasionally we have tested the comparative strength of the adductors and abductors with Osgood's apparatus and have found a definite steady gain in favor of the adductors.

In peroneal spasm massage and exercise alone is able to relieve the condition, but I prefer to add strappings or casts and later plates to the exercise treatment.

NERVE CASES

For a long time physical therapy has been the faithful servant of neurology, and countless are the indications for its various branches. There is no need of discussing the preference of the one over the other, whether massage is better than electricity in a case of paralysis; all have their fields and their limits. To begin with neurosis, there is hardly any field in medicine in which physical therapy can celebrate such great triumphs in the one case and can be so disappointing in the other, though the indications may seem to be just the same. It is better to make a careful prognosis and not to use too many kinds of treatment at once in order to be able to change from one form to another when it seems wise. I begin, as a rule, with general massage to which I add exercise with or without apparatus, hydrotherapeutic applications, high frequency, static electricity, etc.

General massage has given us excellent results in cases of severe hysteric convulsions. Two of those cases had been under observation at the hospital for several weeks without showing any improvement. Soon after massage was started a distinct relief could be noticed and the patients were discharged clinically cured within two or three weeks. Exercises on Zander apparatus have not proved so efficient in this particular class of cases, but they are to be recommended in the depressive forms of psychoneurosis. The effect will be still increased if a strong personal influence can be added to the simply mechanical effect of the exercise. In private cases of that type we always welcome the personal assistance of the physician who sent in such a patient. As to a general indication I would like to say that the anemic cases should be handled with particular precautions.

PARALYTIC CONDITIONS

I have already called attention[1] to the various indications of the exercise treatment of paralysis. I have said that we should consider the effect of the treatment on: (1) the primarily affected neurons; (2) those neurons which are in a functional connection with the former, and those which furnish possibilities of substitution for the destroyed parts; (3) the musculature; (4) the joints and the bones; (5) the internal organs and general health, and (6) the mind of the patient.

In many of the paralytic cases apparatus are of great help in addition to manual massage and exercise. Particularly in the one-sided lesions, as hemiplegia, the use of the bilateral exercise apparatus for active and passive movements and especially those for promotive exercises is of a very definite value. To obtain the desired effect, however, it is necessary to control the patient carefully while he is doing this exercise.

---

[1] Bucholz, C. H.: Exercise Treatment of Paralysis, Am. Jour. Orthop. Surg., May, 1912.

A few words need be said in regard to the prognosis of infantile paralysis. The longer we have had a chance to observe patients the more have we become impressed with the possibilities of improvement in cases of long duration. Many of these patients had not noticed any improvement during years before they started systematic exercise treatment, and it has been sometimes surprising to see how much unused power was stored in muscle groups which at the first glance seemed to be extensively paralyzed. With such experiences we have felt a great deal more optimistic in encouraging the patient to undergo a treatment which certainly will require a good deal of patience and persistency.

Exercise treatment on the one side and operative or orthopedic mechanical treatment on the other should not be considered as excluding each other, as I see it not rarely done in practice. To cite a case recently seen of a girl aged 10 who was operated on in another hospital for spastic paraplegia: So far as I could find out Stoffel's operation had been done on the obturator nerves. As her mother said, there had been a distinct improvement during the first few months after the operation, but the child was left to herself without any attempts of after-treatment, and she is worse now than before, probably also with the prognosis made worse. I thoroughly agree with men like Biesalski, Foerster, Lovett and others that, unless such a patient, after either a simple tenotomy or Foerster's or Stoffel's operation, can enjoy a careful after-treatment in the way of educative individual exercise given with the full understanding of the situation, the operation should better be omitted.

Of other nerve lesions not grouped under neurosis and paralysis, we have had to treat spasmodic torticollis, paralysis agitans, multiple sclerosis, and once in a while a case of tabes. In a few cases we have given Frenkel's treatment for locomotor ataxia, but have never had a chance to carry it through a sufficiently long period. The value of Zander exercise in this class of cases is from our experience not very great.

INTERNAL CASES

Last of all I come to speak of the internal medical cases. The statistics presented in the table show a very small percentage of medical cases, compared with surgical, orthopedic and nerve cases, a percentage which is in a striking contrast to German institutions of the same kind. It is very much to be regretted that our medical men do not make a wider use of massage and exercise in the treatment of their cases, although publications of authorities in physical therapeutics as well as our own experiences have been very encouraging. Without going into details of a theoretical discussion, I should like to call your attention to the most important indications.

In cardiac cases exercise is of value in that stage when compensation has been reestablished. The stout persons are better subjects for exercise treatment than the slender anemic ones, and indeed, in the first group of cases we have seen some very suggestive results. One patient of middle age with a severe myocarditis and adipositas recovered during three months of faithful treatment by exercise and diet to his full power and strength, while he lost at the same time 35 pounds in weight. Frequently we combine the exercise treatment with carbon dioxid baths, thus making a combination which is known under the name of Nauheim treatment. The greatest difficulty in prescribing exercise treatment is the exact measure. We know that the effect of massage and exercise on the blood-pressure and on the pulse rate differs within wide limits according to the localization and amount of massage and according to the speed, time and amount of exercise. It was the desire to obtain an exact measurement and dosage that led Zander in planning and constructing his apparatus, and we believe that for cardiac cases the exercise treatment with Zander apparatus or with apparatus of a similar construction is superior to any other form of exercise treatment. Instruction in the use of the apparatus and a certain amount of control and supervision are necessary. In every medical case we have the pulse recorded before and after treatment and, if indicated, once or twice between.

Occasionally we take the blood-pressure before and after treatment, an examination which is done as a rule before and after the Nauheim bath.

Among the affections of the respiratory system the chronic bronchitis, the chronic adhesive pleuritis, and the late postoperative stages of empyema are especially suitable for exercise treatment. We have had some of those patients recover in a very satisfactory way. In one-sided pleuritic lesions asymmetrical exercises play a prominent rôle. In bronchial asthma and emphysema the exercises favoring expiration have proved to be of a decided value.

Of abdominal affections, chronic constipation has long since found particular attention from the point of view of physical therapy. Massage, gymnastics and hydrotherapy have been equally well recommended and all have a very definite value. But I believe that in a condition like this we should not depend on one or the other form of physical treatment without paying sufficient attention to the whole mode of life, the diet, the habits, etc. We must consider that in many of these cases the trouble is perhaps not so much local as constitutional and that an improvement is often far from a real cure, that relapses are apt to follow, unless radical changes in the whole life are made. But keeping these factors in mind, massage and exercise may become of greatest help. A number of Zander apparatus are particularly constructed for abdominal massage. I do not depend on this form of massage, which is in my opinion very much inferior to an intelligent manual kneading of the abdomen. But aside from this, Zander apparatus are very useful in the treatment of chronic constipation. It is necessary to keep up the treatment for a considerable length of time, if possible, to make it a kind of habit. This is particularly true for cases of chronic constipation, connected with adipositas and poor circulation of the internal organs, patients who are sitting most of the time, and do not have enough exercise. In German Zander institutions I have seen many elderly men of that type who came for exercise three times a week the whole year round.

CONCLUSION

I am at the end. It has been my purpose to show you the many and various ways in which a medicomechanical department can serve a large general hospital. It is not enough to have just a number of apparatus running, but the whole mechanism of massage and exercise treatment must be set to work; the treatment must be conducted not as a routine, but with the full understanding of physiologic and pathologic laws. Finally, and this is the most important point, such a department must have the intelligent and wilful support of the whole hospital and all physicians must feel that it is not an institution for the worst type of cases, but that it can show good results only when the indications for which the patients are sent are wise and the previous treatment has been the best.

139 Beacon Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BIERRING AND BUCHOLZ

Dr. A. B. Hirsh, Philadelphia: We send patients to European specialists who use physical remedies, find that the former return much benefited, often cured, and then, uninfluenced by this evidence, still proceed with our old methods of strict drug therapy. On the other hand, certain features of physical treatment have hitherto been resorted to by those without scientific training, or who, if they had any technical knowledge, used modes of exploitation that aroused the antagonism of ethical practitioners. At least four large Philadelphia hospitals have modern hydrotherapic plants, those in charge being properly taught; one of these has a special building for hydrotherapeusis. Some private institutions, also, have introduced this and other newer modalities, all largely due to the wise propaganda of Simon Baruch. One can agree with Dr. Bucholz that, too often, patients are sent us for electrotherapic measures by medical men, who, unfortunately, are not informed on this and kindred measures. For instance, a patient was referred for obesity with the recommendation that vibrassage be applied over the abdomen, when, instead, oscillation and the static wave current were plainly indicated. Another case was that of a badly sprained ankle with much organized inflammatory deposit for which again vibration was insisted on. In these cases only failure could result, the mistaken methods asked for naturally getting the blame. When Dr. William B. Morton in the early eighties came back from Charcot's clinic in Paris where he had seen, through application of a static wheel of the simpler type, the value of even that small machine in nervous disease of plainly organic type, the outcome of his thinking was the modern American high-frequency static apparatus. By means of this a group of physicians over the country, scientific, ethical, are now treating patients referred to them by confrères with results practically unattainable by other methods. Why not apply this plan in each hospital rapidly to awaken the medical public to its possibilities? Some time ago I was asked whether I would care to create such a department in a large hospital in Philadelphia and as many assistants were offered as might be required. My answer was that, until those young graduates could be properly trained in the physical laboratory, the responsibility of treating the variety of cases met there would be too great, because blame for the inevitable mistakes and failures must finally fall on the chief. One must have accurate knowledge of the physics of electricity before apparatus of this high voltage can be correctly applied. When the undergraduate schools realize this fact, more bright students will go into these departments of hospitals and develop their opportunities. We must realize that there is no special field in medicine that must not have added to its armamentarium some phases of the more recent changes in physical treatment. In a few years we shall see the scientific basis of this important part of physical therapy generally recognized.

Dr. C. Hermann Bucholz, Boston: There is a danger in special institutions of physical therapeutics. We have this danger in Germany as well as here, but we must use the help of the man who is more trained in his special line of work. The danger of such special institutions lies in the fact that the man in charge often has cases sent to him with the wrong indication but treats them nevertheless. In our Massachusetts hospital we accept private cases and sometimes they are not properly diagnosed. In a case of chronic urethritis nothing had been done to find the focus. There was a most important indication overlooked in that case. I believe that someone who calls himself a specialist in physical therapy treated that case nevertheless. Meyer of Dresden, one of the greatest German authorities on this subject, says there should not among physicians be a specialist in that line; there should only be a specialty as to the teaching. I thoroughly agree with that. Another point is the training of young physicians in this subject. It is surprising how difficult that is. In our orthopedic department, where about fifteen or twenty physicians are working, there are a lot of young men, who, I am sure, would have the time, but when asked what they would do they could not tell. I tell them they ought to be ashamed to call themselves orthopedic doctors and not know anything about this treatment.

COUNTY HEALTH ORGANIZATION IN THE UNITED STATES*

LOUIS I. DUBLIN, Ph.D.
Statistician, Metropolitan Life Insurance Company
NEW YORK

County health organization in the United States is especially significant in relation to the problems of rural sanitation. The campaigns of the last three decades have resulted in the establishment of active and fairly efficient offices of health in the cities. The concentration of people into the cities and the larger financial resources of these communities have made such service absolutely necessary and possible. In the country, on the other hand, the need for efficient health work is apparently not so imminent, funds are not as available, and as a result, this phase of community work has been slightly developed. With few exceptions, there is very little health control in the rural sections of the United States. It is the purpose of this paper to suggest a system of county health organization which, it is believed, will help to coordinate the several health functions of the state and to lay firmer foundations for the control of rural sanitation.

COMPARATIVE DECLINE IN URBAN AND RURAL MORTALITY (IN REGISTRATION STATES AS CONSTITUTED IN 1900) FROM ALL CAUSES •

	Death Rates per 1,000 of Population						Decline in Death Rate '12 from '00	
	1900	1905	1910	1912	Av'ge '01-'05	Av'ge '05-'09	Actual	Pct.
Registration states ..	17.2	15.9	15.6	14.6	15.9	15.5	2.6	15.1
Rural part of registration states	15.2	14.4	14.7	13.9	14.1	14.2	1.3	8.6
Cities in registration states	18.9	17.1	16.2	14.9	17.4	16.4	4.0	21.2

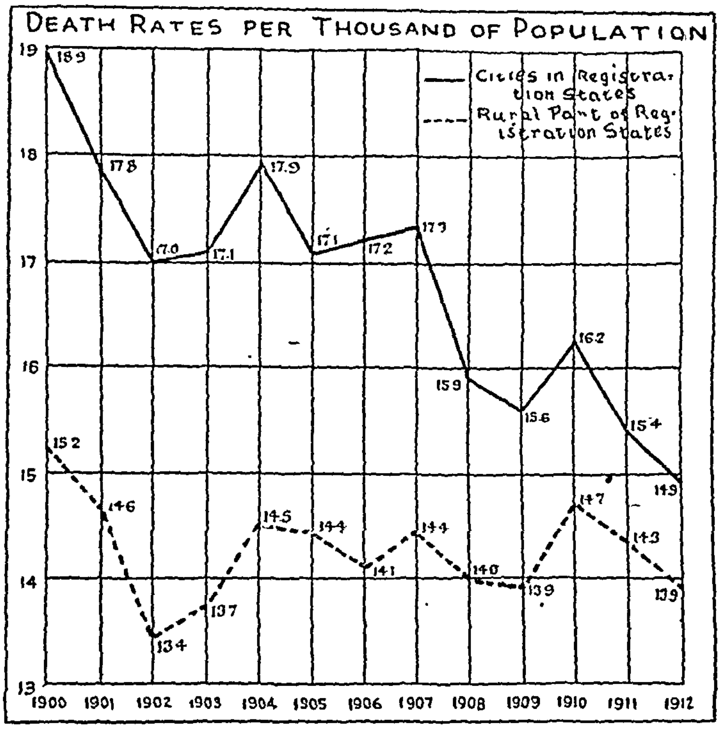
A few statistics will help to a clearer understanding of our subject. The death rate has materially declined. In 1900, it was 17.2 per thousand living in the registration states and in 1912, the rate for the same states was only 14.6, a reduction of 2.6 per thousand, or 15.1 per cent. This decline in mortality, however, was much more pronounced in the cities, where the rate fell 21.2 per cent. in the twelve years under discussion, as against a decline of only 8.6 per cent. in the country districts. These figures (given in the table and chart) do not portray an accidental condition but are descriptive of a pronounced tendency in American mortality in the urban and rural sections of the country.

These death rates, to be sure, do not contain any allowance for the differences in age and sex composition of the population in the rural and urban districts. But the importance of this fact must not be overemphasized, for when the rates are standardized, the changes will be found to be slight and will scarcely affect the comparative rates of decline. There are other and more important elements of population composition than age and sex that should be considered in this connection. The country districts are the homes of the native stock of America, while the cities receive annually hordes of emigrants from Europe, whose mortality is and has been for years much higher than that of our American stock. In like manner, the colored race with its high mortality rate is almost twice as largely represented in the cities of the registration states as in the rural sections. If, therefore, a complete standardization were made of the death-rates presented in the chart we should find that the small advantage still in favor of the rural area in 1912 would be still further reduced if not entirely obliterated.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

The explanation of the conditions we have just observed in the death rates of the city and the country lies largely, I think, in the differences in the efficiency of their health services. Yet it is in the rural section of the country that more than one half of the people of the United States still live. In 1910, 53.7 per cent. of our population were located in centers with populations under 2,500. In spite of the growth of our cities, America is still, and by necessity must long remain, largely rural in character. It is to the country side, therefore, that we must turn for many years for our most profitable life conservation work. No greater opportunity awaits the American Medical Association and other bodies interested in improving health conditions than to concentrate their energies to this section of the country and to accomplish, if only in a limited manner, what has been done in the American cities.



A comparison of urban and rural mortality (in registration states as constituted in 1900) from all causes.

The key to the solution of the problem of rural hygiene lies in the development of efficient county health organizations in the United States. In most states, the chief unit of local government is the county. There are 2,953 counties in the United States. The typical county is one of about 600 square miles in area with a population of about 20,000 so that every point of it is readily accessible from the county seat. Five-sixths of these counties are rural in character; fully 10 per cent. have no incorporated places and about half contain no towns with as many as 2,500 people. The American county, however, has not as yet been aroused to the fact that it has distinct health functions to perform and that it is the only governmental unit that can properly and efficiently perform such functions. The county health officer should be the most important single factor in conserving American public health, but is practically the weakest link in our entire health system.

To obtain a more intimate view of county health organization in the United States, a questionnaire was sent by the Statistical Bureau of the Metropolitan Life Insurance Company to the executive health officers of all the states. We inquired into the provisions of the state health laws; into the organization of the departments; whether there were any county health officers and whether they were full-time officials; how these men were compensated; the amount of their compensation; and to whom they were responsible. Finally, we inquired into the need for full-time county health officers in the several states.

From our replies it was at once evident that we were concerned with a vital question. The answers were usually complete, clear and to the point and indicated that the subject of our inquiry was in many states the chief concern of the health authorities. The following is a brief summary of our replies:

Health administration is organized on the county plan in thirty-one states out of the forty-one that replied. Yet only five had arranged for full-time county health officers in any of their counties. These were Oregon and Washington, which have one full-time county health officer each; Colorado and Florida, which have two each, and North Carolina which has eleven. In the other states, county health officers are part-time officials, if in existence at all.

In most states the compensation of the county health officers is determined by the local county commissioners or supervisors. In Louisiana, health officers are paid by the police jury of the parish and in Missouri by the county court. The county health officers of Florida are the only ones reported to be on the payroll of the State Board of Health. From all replies, however, we could infer that these health workers received entirely inadequate compensation. In many cases $100 a year was the total salary paid. In one state, fifty-six out of one hundred health officers received less than $200 annually, and this state has recently made considerable progress in its provision for county health service.

The county health officers of more than one-third of the states are responsible to local authorities only. Training in public health and sanitation is not required as a prerequisite for office. There is little, if any, provision for laboratory work. Tenure of office is insecure and the machinery is political rather than scientific.

The one encouraging note in our replies was the almost unanimous demand for full-time county health officers. In this connection the health executive of one of our Eastern states expresses the opinions of almost all of our correspondents when he says: "Yes. We feel the need for full-time county health service every day — all day."

We may, therefore, conclude from these answers to our several questions that full-time county health officers are an absolute necessity in most of our states; that very few such officers exist; that they are insufficiently paid; that responsibility to the centralized authority is lacking, and that county health work is only too often intimately connected with local politics. The present system of county health administration in the United States is inefficient and not conducive to the public welfare. The health officer of a large Western state aptly struck off the whole situation when he said: "The present system is not efficient and never can be."

What then is the solution to the problem presented by county health administration in the United States? It must be obvious that no system will be equally applicable to all the states. A plan that is practicable in New York may very well prove ill adapted because too expensive for a number of our Western or Southern states. Local conditions, both geographical and economic, will largely determine the details of organization. It is agreed, however, that certain fundamental considerations apply equally to all the states which have extensive rural populations, the local control of which is on the county plan. I propose to review briefly some of these requirements.

1. The county health organization of a state must be an integral part of the state health administration and be responsible to it. Public health protection is primarily a state function. The county health officer and the county board, whenever there is one, should, therefore, hold themselves in readiness to enforce orders from the state department. They should, moreover, be subject to removal by the state department for cause. The state, on its part, however, must recognize this dependence of the local organization through state subsidies to help cover the necessary expenditures for county health work.

2. The county health officer must be a full-time official. He must be one whose sole interest is in the community, to the exclusion of private interest, be it his own or that of private individuals or groups. We all know too well how often the part-time health officer who has a private practice to maintain must choose between the performance of public duty and the loss of his practice. This situation should not arise. He should never find it necessary to compete with those whom it is his duty to supervise.

3. The county health officer should be trained in the science of sanitation and public health. Most practicing physicians are not well enough equipped to administer a progressive health office. The protection of the public health, as now conceived, is a science with its own data and formulas. The larger medical schools, such as those at Harvard and at the University of Michigan, for example, have organized special postgraduate courses leading to the degree of Doctor in Public Health. It will be a great day in American public health affairs when medical officers will, as a class, qualify by study in such postgraduate courses.

4. The tenure of office of the health officer should be coextensive with his efficient service. The successful health officer is made, not born. With a proper background of training, every year of added experience makes him a more useful servant of the state. The health officer should, therefore, be assured of a continuous tenure of office. He should in no way be a pawn in the political game. A period of six to eight years has been suggested as a sufficient term. Health officers who have made good should then be considered for reappointment, although the state may reserve the right to dismiss in shorter time those who are incompetent or neglectful of their duties.

In view of these requirements, it should hardly be necessary to point out that county health officers must be reasonably compensated for their services. Surely, if full time is required, the compensation must be sufficient to attract and to keep good men in the service without inflicting hardships on them or their families. It is folly to set high standards and to make them impossible of attainment because of inadequate compensation or uncertainty of tenure. Salaries must be adequate to attract able men and to maintain them in a state of comfort consistent with their important duties.

Permit me to point out more definitely the character of the return that awaits the states on their investment in full-time county health officers. In spite of all our preconceived ideas as to the healthfulness of the country, the rural sections suffer severely from the ravages of tuberculosis. Such typically rural states as Kentucky and North Carolina (using these as examples) suffer a death-rate from tuberculosis higher than that for the registration states taken as a whole, and higher than for the registration cities. It would be the first duty of a full-time health officer to address himself to the tuberculosis problem of his rural communities.

The typhoid problem is equally urgent. In 1911 the death rate from this disease was 22.2 per hundred thousand in the rural section as against 18.6 in the cities of the registration states. These figures in themselves clearly indicate the many sanitary dangers incident to life in the country. Typhoid fever is always, to the health engineer, an unerring signal directing him toward polluted water supplies, infected food products and unsupervised typhoid carriers. These are a constant menace to the entire state through their effect on milk and other food supplies. All of these sources of typhoid infection, including the disposal of dangerous waste products, lend themselves to the concerted efforts of modern sanitary science. Indeed, no disease has shown such a ready response to control as this preventable filth disease. The full-time health officer, supported enthusiastically by his community, would in the course of his first administration, earn many times his cost in reducing sickness and death from this cause alone.

The full-time health officer would of course participate in other lines of health work. His influence would soon become evident in reduced rates of sickness and death for the other preventable diseases. In no one respect, however, would the services of the full-time officer be more constructive and remunerative to the community than his active participation in child hygiene. In the larger cities throughout the country, this phase of health administration is now permanently established. In the country, on the other hand, this work has not received any serious attention. Children are not so well housed or so well fed in the country as in the city, and school buildings are so poorly constructed that the children are often exposed to conditions of weather and infection which bring about disease. It would be the function of the full-time county health officer to work in cooperation with the school authorities of his community and to see that each child in his jurisdiction is examined for physical defects, at least once a year. If there were no better excuse than the need for some local authority to carry on intelligent and modern work in child hygiene, the states would be justified in appointing full-time county health officers for this purpose.

I need hardly point out to this audience the multitude of ways in which a well-trained and full-time county health officer would serve the state. I need only refer, in addition, to his influence on the vital statistics of his county. While no attempt should be made to burden him with the duties of local registration, his very presence, especially when fortified with an efficient laboratory, would serve to bring together most valuable records of the incidence of the communicable diseases, as well as to improve the registration of births and deaths.

In closing, may I suggest that the committee of your section which has been appointed to study this problem cooperate with the committee of the American Public Health Association with a view to formulating a model bill on the subject of county health administration? This task should not be a difficult one at this time. A number of states, including Kentucky, Maryland, Georgia and Kansas, have either passed laws for county health service or are actively engaged in studying the question. Other states, judging from the character of the answers to our questionnaire, are intensely interested. It should be possible, through conference and study, to determine what a county health bill should contain, and the endorsement of such a measure by this body at a subsequent meeting should be most helpful in placing it on the statute books of a number of states. I can conceive of no more promising field of work for the American Medical Association and especially for the Section on Preventive Medicine and Public Health.

ABSTRACT OF DISCUSSION

Dr. Wm. M. Perkins, New Orleans: With the major argument of Dr. Dublin's paper I agree most heartily. The necessity for more definite organization is apparent. We are fighting the health campaign very much as an untrained mob would fight. That more definitely trained and equipped health-officials are needed is not disputed; nor that there is a necessity for permanent health-officials who thus would have some encouragement to undertake this special work. A health-official cannot be, as a rule, a practitioner at the same time. The health-officer is forced to come into such relations with the rest of the medical profession of the state that whenever political changes remove him he is put in a very bad position with regard to resuming practice. Therefore, men everywhere are hampered in their health-work by the necessity of making a living when the powers that be remove them. There is no more apparent root of evil in the health administration of the present than the constant political changes of health-officers and their domination by politics, and the insufficient guaranty of reward for faithful, persistent and trained effort. With regard to the organization of a proper health army, it has two aspects. One would be to enlarge the powers, duties and responsibilities of the county health-officer as far as possible; then the state health-officer could, to the limit of the state's powers, take up those things which the county health-officer was not empowered to handle, and could leave to the national health-service the matters beyond his own jurisdiction. I am strongly in favor of enlarging the present bureau of public health into a full set of furniture, making it a department, and giving the national health-service as many powers, duties and responsibilities as may be required. The state health-officer then would carry the work as far as he was able, and the local health-officials would be left as little as was necessary. Instead of putting the burden on the lower officials and building up, I think it should be put on the higher officials and built down. I doubt whether the wording of the phrase "full-time county health-officer" is exactly correct. "Full-time health-officer," by all means; but probably it would work out better if the scheme were adopted to a district rather than the county, as Dr. Dublin suggests. In Louisiana we recently tried the plan of suggesting a movement to redistrict the state, cutting out the forty-odd parish or county health-officers, and putting in a small body of full-time district health-officers. The very element of politics and the ambition that men have to hold positions of county health-officers—to which they give little time, little training, and from which they accomplish, many times, little result,—rendered these positions so attractive, and of such honor and glory, that the incumbents fought vigorously not to lose them.

Dr. W. H. Sanders, Montgomery, Ala.: The question of securing adequate compensation to command the entire time of health-officers for the counties is being agitated in all of our states, and the outlook for the early future is growing brighter and brighter.

For eight or ten years, in my state, we have been working to this end. All we need to accomplish our object is to convince the people of the value of such an officer. Eight or ten years ago we secured a law laying down a minimum below which the authorities of a county could not go in fixing the salary of the county health-officer; but we put no limit above. They have had the right for all these years, and enjoy it now, of providing a salary adequate to command the entire time of a health-officer for the county; and we hope, in the near future, to see a number of the counties in my state availing themselves of their privilege, one county having already done so. The only obstacle is the lack of education of the people as to the need of such an officer and what he may do for them. I am glad to say that we are not confronted or surrounded by any of the difficulties mentioned by Dr. Perkins. We in Alabama, fortunately, are absolutely divorced from politics in our public-health administration. The election of health officers is vested in the organized profession; the doctors, in their organized capacity, name every health-officer in Alabama, from the state health-officer down to a health-officer for the smallest municipality. Our people approve this feature of our system, and we have never had any difficulty in maintaining it. With us it is simply a question of the education of the people as to the need of full-time county health-officers.

Dr. W. S. Rankin, Raleigh, N. C.: Dr. Dublin called attention to the fact that our state had more full-time health-officers than any other state that he had replies from. We have eleven whole-time county health-officers in North Carolina. There are 100 counties in the state. We could have had, if we had pushed our campaign along quantitative rather than qualitative lines, twenty or thirty counties. I believe what I say with regard to the counties of North Carolina would apply to the counties throughout the South. There is comparatively little difficulty in persuading a county to employ a whole-time man and to appropriate from $2,500 to $3,500 for the salary and expenses of such a health-officer, requiring him to own an automobile. Of course, a whole-time man with an automobile is worth two without one. To get whole-time health-officers in the counties is easy, and I will give our methods to anybody that wants them. After the officer is obtained, the troublesome thing is to get him to do the right kind of work. Dr. Dublin recommends that the state shall have power to require the whole-time officer to perform certain duties. That is about the only way that this system of county health-work will amount to anything. My first idea was, after the whole-time men were elected, to have them take three or four days to confer concerning their four or five definite fundamental duties; then for them to adopt some system of work embodying these duties. The report should be such that, when published by the state board of health, it would be comparative. I derived my idea from the work of the Rockefeller Commission in the South. Their men are all doing the same kind of work, making the same kind of report and using similar report blanks; at the end of each week the results are published in such a tabulation as to make a comparative showing for each man. Instead of statutory power to compel these men to do certain things, we simply wanted to use that powerful law-enforcing power in American life—the power of publicity—to make them do their duty. If we could have gotten them to adopt a uniform standard of work and a uniform monthly report, and then published the work of each man, each month, in the health bulletin distributed throughout the state, and in the newspapers, we would have all the power that we need.

When the whole-time men came together, however, they decided that, inasmuch as some of them were inexperienced in health-work and the whole thing was experimental, they had better not establish any uniform plan to begin with, but rather should spend six or eight or twelve months in the field and find what work was needed, then later, perhaps, adopt a uniform standard of work.

Dr. J. W. Trask, Washington, D. C.: I think both Dr. Dublin's paper and its discussion show distinct progress in the evolution of health administration in this country. It is especially interesting, in my opinion, as showing the approach of the second step in health organization. I believe it is logical to assume that the state, being the larger unit of population and the larger political jurisdiction, will develop an efficient health department before the counties do. I take it that Dr. Dublin presupposes full-time state health-officers. Unfortunately, that is not so throughout all the country; but I do not believe that the development of the county organization should be delayed on that account. The position of state health-officer is not only one that requires an able man, but requires all his time. I do not believe that it is compatible with proper state health administration that the state health-officer should be devoting his attention to other things and his official work constitute a side line. Dr. Dublin's logic is sound, and, assuming that the necessity of full-time state health-officers has been established, it is time to strengthen health administration in the next smaller political subdivision of territory. It does not necessarily mean a county. I think that the county, however, having already a political organization, will in most instances be found the most suitable and convenient. The progress of health organization is undergoing a natural evolution. It was first appreciated that the state needed all the time of its health-officer. It is now apparent that the county also needs a full-time health-officer. In time further needs for full-time health-officials will undoubtedly be found in territorial subdivisions smaller than counties where the population is sufficiently great.

Dr. S. A. Knopf, New York: We have heard a good deal of the duties of the health-officers, but nothing of their rights. It seems to me that any health-officer without police power is but a feeble power in his community. I had occasion recently to examine some country schools, and, to my amazement, I found that the hygiene in those schools is sometimes many times worse than in cities. In many communities I have found that the health-officer has no control over the tuberculous patients who, because of ignorance or indifference, infect not only the members of their own families but their close neighbors and friends. If the health-officer of any community is not empowered to remove such dangerous patients to a place of safety, I mean where they will not be allowed to spread their disease, I cannot see the utility of the office in relation to tuberculosis. Unless the health-officer can order an unsanitary school to be made sanitary, he is but a weak factor in his community. I highly approve of all Dr. Dublin's suggestions. I hope those in power will propose bills and help in the enactment of laws whereby the health-officer of any community, small or large, shall be given police power to enable him to enforce the sanitary regulations whereby the whole community is to benefit.

Dr. A. T. McCormack, Bowling Green, Ky.: I want to express my appreciation of Dr. Dublin's excellent work. I think nothing went further in showing the members of our recent general assembly the wisdom of legislation creating full-time health-officers than the publication which Dr. Dublin distributed in Kentucky. The value of such essays distributed to the people has been greatly emphasized in our state, and I am glad to express the gratitude Kentucky feels to the Rockefeller Sanitary Commission for the Eradication of Hookworm Disease for the opportunities it has given to the people of Kentucky to see actual demonstrations of what a full-time health-officer can do. The health campaigns which have been conducted in Kentucky in connection with this commission, this dispensary work, with a trained sanitary inspector in charge, with expert microscopists, with the trained workers in the warfare against tuberculosis conducting campaigns of from three weeks' to three months' duration in many counties, carrying the lessons of better health and longer life into the rural homes and country stores and schools and churches, are in this way best enabling the people themselves to realize what would be possible if each county could have a man devoting his entire time and energy to this work, assisted and supported, as he would be, by the organized medical profession and an educated public opinion. There was not an intelligent or thinking member of our recent legislature from a section in which these dispensaries had been held who was not only in favor of the creation of a full-time health-officer, but was more in favor of this legislation than any other matter before the general assembly. In Kentucky more than 200,000 men, women and children have been examined for intestinal parasites, and nearly half of them have been found to harbor hookworms or some other variety. If the Rockefeller Sanitary Commission had accomplished nothing else, if not one of those infected had been treated (and practically all of them were treated), the change of sentiment brought about by the demonstration to our people of the accurate sanitary methods of modern medicine, their increased confidence in their family physicians, their increased desire for better and more practical education in preventive medicine, would have justified the expenditure of all the money and energy which has been put into the work.

L. I. Dublin, Ph.D., New York: Dr. Rankin's experience should prove most valuable to every state health-officer. It seems to me like a hopeless task to begin with the idea of local autonomy, although there is always a great temptation to do that. As Dr. Rankin has pointed out, there is the strong possibility that a group of county health-officers will combine for selfish purposes and defy the state department to compel them to do the right thing under the law. Unless they are appointed subject to the approval of the state department and can be removed from office by the state department, the administration of the county health service is very likely to become political and of little value. I therefore hope most sincerely that the committee appointed to report a bill for full-time county health-service will have in mind a system in which the state is the central authority, the several county officers being at all times responsible to the state and subject to its control. A bill which will have the approval of your organization and that of other national organizations like the American Public Health Association will have great weight with the state legislatures and is very likely to be enacted into law.

The Need of a Knowledge of Anatomy.—A disease must always have a relation to a healthy action, or healthy structure of parts, for it is only a deviation from them; so that a knowledge of disease would appear to rest on a knowledge of the body in its healthy state. It is in this point of view that anatomy and physiology become so very important, as being most likely to afford the means of relieving the body when suffering under disease. If anatomy, then, be of so much use in physic surgery, it ought to be earnestly cultivated by those who really wish to know their profession, and to become respectable in it. This is not a trifling matter. Justice and humanity require every exertion where the lives of our fellow-creatures are concerned. There are many professions where negligence or inattention may be reckoned a folly; but in medicine it is a crime. There is nothing that renders a person more fit for the discovery of new diseases, than a knowledge of anatomy.—Matthew Baillie.

A REVIEW OF CURRENT HOSPITAL TOPICS *

L. B. BALDWIN, M.D.
MINNEAPOLIS

After considering various topics on which to address you it appeared to me that the interests of the Section on Hospitals would be best served by an effort to emphasize further the importance of certain matters affecting the conduct of hospitals which are of special interest to the hospital administrator, and worthy of the consideration of the medical profession generally, and with which you are already more or less familiar.

The object in thus bringing them to your attention is to stimulate this Section to interest itself further in them as a body, to the end that it may exercise the influence for greater hospital efficiency of which it is potentially possessed, and which I believe to be its greatest function.

If the Section on Hospitals is fully to justify its existence it must assist, so far as possible, in promoting the aims of the other component parts of the parent organization. In return it may expect of them a fair consideration of and cooperation in the problems peculiar to itself.

While some of the matters to which I shall refer are not of recent origin, it is only during the last few years that their importance has come to be so generally recognized as to result in active efforts to secure their realization. These efforts have been inaugurated in part through the initiative of individuals who have been directly concerned in hospital administration, and partly as a result of certain demands arising from without the domain of hospital management.

Most prominent among the latter are the demands of medical education for larger and more efficient hospital facilities for the purposes of instruction in the clinical branches of medicine. These demands have been met in different places in various ways; but in no instance without involving hospital organization and standardization. These, I believe, are the most important subjects concerning hospitals of mutual interest to the different sections of the American Medical Association to-day. They are interdependent, and the ideal of hospital efficiency for which we are aiming cannot be realized without giving them the careful consideration which their importance indicates.

It is not my purpose to discuss the relative merits of different types of organization, or to suggest that the subjects of hospital organization and standardization should be approached from the point of view of medical education alone, but rather to urge, since they are of such great importance to hospitals, that they be considered and acted on in a broad way.

It must be admitted that the relationship between medical education and hospitals is such that the one cannot develop higher ideals and standards without the assistance and cooperation of the other. Hence, the problems of medical education become, to a great extent, the joint problems of the hospital administrator and those directly concerned in medical education.

Therefore, the best types of organization for the different classes of hospitals and the principles and methods to be employed in the general standardization of hospitals can best be determined through the cooperation of those representing the different interests involved. For this reason it would seem just and desirable that the Section on Hospitals be represented on the Council of Medical Education, and I would recommend that action be taken at this session to secure such representation.

A study of different hospital organizations which have recently been effected demonstrates that there are differences of opinion as to what type of hospital organization best serves the interests of medical education, but there is no disagreement on the proposition that, generally speaking, organization can be improved on.

Justification for the present existence and further extension and development of hospital organization of a type which brings the public wards, at least of the larger hospitals, in closer affiliation with medical schools is found in the experience of those hospitals in which such organizations have been in effect. The fact that the hospital so organized is benefited by such close relationship has been amply demonstrated. Just why the idea that the admission of medical students to the wards of hospitals for the purpose of receiving clinical instruction under proper supervision is inimical to the welfare and proper care of patients should have obtained so long in this country is not clear, especially in view of the fact that intimate connection between medical schools and hospitals has existed for centuries in England for precisely that purpose.

It may be said that, so far as medical education is concerned, the ideal hospital organization is that suggested by Abraham Flexner in his report on medical education in the United States and Canada. In this connection he says:

> The patient's welfare is ever the first consideration; we shall see that it is promoted, not prejudiced, by the right kind of teaching. The superintendent must be intelligent and sympathetic; the faculty must be the staff, solely and alone, year in and year out. There will be one head to each department—a chief—with such aides as the size of the service, the degree of differentiation feasible, the number of students, suggest.
>
> The professor of medicine in the school is the physician in chief to the hospital; the professor of surgery is surgeon in chief, the professor of pathology is hospital pathologist.

That the difficulties which may be, and usually are, met in attempting to apply an organization of such general character to large public hospitals are not wholly insurmountable is evidenced by the type of organizations planned for the new municipal hospitals of Cincinnati and Louisville.

The municipally supported or privately endowed hospital which, given the opportunity to affiliate through its organization with a medical school of recognized standing, does not avail itself of the privilege, is not fully discharging its obligations to the community it serves.

The value of one thing in connection with hospital organization deserves special emphasis. The larger hospitals at least should each include, as a part of the staff organization, a committee, the chief function of which should be to promote professional and administrative efficiency. This committee should be made up of a staff member from each hospital service, or division, and the superintendent or his representative. The membership thereof should be as small as practicable. The suggestion for, as well as a reference to the importance and value of. such a committee was

---

* Chairman's address, read before the Section on Hospitals at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, June, 1914.

included in the address of Dr. F. A. Washburn, president of the American Hospital Association, last August. This matter is also urged on us by the Committee on the Standardization of Hospitals of the Clinical Congress of Surgeons of North American in connection with another matter which will be referred to presently.

Concerning the general standardization and classification of hospitals, progress has been made. The questions involved have been ably presented and discussed at various times by many, including the secretary of this Section, who has been actively engaged with others in promoting plans for its accomplishment, and to whom much credit for the advance is due. The action already taken in this direction by the Section on Hospitals was approved by the adoption of a resolution presented at the last meeting of the American Hospital Association by Dr. Hurd, providing for the appointment of a committee to consist of three of its members to act with a similar committee of this Section and cooperate with it in promoting the measure.

Any standardization which is to become effective and acceptable must of necessity be based primarily on a classification of hospitals and the character of the service which each renders to the community it serves. To adopt methods of standardization which overlook the opportunities to assist the smaller, worthy hospitals to effect still higher standards would be unfortunate. On the other hand, the principles and methods employed must be sufficiently comprehensive to put the so-called hospitals which permit or condone objectionable or criminal practice in a properly designated class by themselves. That such hospitals do exist is a recognized fact which must not be overlooked in the determination of principles and methods of standardization.

That some system of periodic, competent inspection of hospitals is desirable is generally admitted by hospital administrators. How best to obtain this is a matter with which the Section on Hospitals should concern itself. Some system of inspection must precede any standardization undertaken, and be continued permanently thereafter if the desired results are to be obtained and perpetuated.

The Council on Medical Education has wisely considered the whole subject of hospital standardization in a general way from the point of view of medical education and is now preparing for publication a provisional list of hospitals acceptable from the standpoint of furnishing satisfactory training for interns. This provisional list will shortly be published and will amount to a temporary standardization of hospitals in that direction. In this connection the Council has arranged for the appointment of advisory committees in different states to assist in this work, and the provisional list will later be revised on the basis of reports submitted to the council by these several committees. What action, if any, will be taken by the Council with reference to the further and more general standardization of hospitals remains to be seen. Obviously it is not within the province of the Council on Education to concern itself to any great extent in the direction of those hospitals in which clinical instruction cannot, for one reason or another, be undertaken.

The program of this meeting of the Section on Hospitals bears testimony that there are other things requiring attention in the direction of standardization.

Who of us has not noted the diversity of surgical technic exhibited by surgeons equally competent in diagnostic ability, surgical judgment and operative skill? Why should two or more equally competent and reliable surgeons demand different types of surgical apparatus, equipment or instruments to accomplish the same result in a given case? If such a diversity of technic were essential to the welfare of the patient no question could or would be raised concerning it. That it is not essential is amply shown by the statistics of certain hospitals wherein differences of surgical technic obtain.

Since autostandardization of the surgeon is being attempted, the least the hospital administrator can do is to afford every facility possible to make its accomplishment both sure and rapid. The measures which have been institutel in this direction, notably the creation and organization of the American College of Surgeons, are based on a recognition of the fact that there is still ample opportunity for improvement, notwithstanding the marvelous progress made by surgery in recent times. These measures conscientiously followed out will ultimately result in the further elevation of the surgeon, and incidentally the hospitals, in the confidence of the public.

A criticism of the statistics usually embodied in the reports of general hospitals has recently been made from at least two sources. That ultimate results of the care and treatment of the patients covered in most reports are not indicated, is plain. There is a demand, on the part of the profession, for a revision of the form of these reports based on a follow-up system. The report of the Committee on Standardization of Hospitals of the Clinical Congress of Surgeons of North America covering this matter was adopted at the meeting of the congress last year and the report has been generally circulated. Statisticians are also free in their criticisms of the form of most hospital reports, and the criticisms from both sources are just. We, as hospital administrators, would do well to act on the suggestions for improvement in this direction already made and put them into effect as promptly as possible.

Details of hospital construction are never without interest to the hospital administrator. Our attention is called to the necessity of ascertaining certain scientific facts on which intelligently to base standards for the ventilation of hospitals. This matter will be brought to your attention in detail during this session and the Section requested to lend its influence by supporting some measure looking to an investigation and report on the subject by a properly constituted body.

One cannot consider the subject of hospital construction in this country without being impressed by the vast amounts of money which have been and are now being expended in the erection of buildings for hospital purposes. There is a well-founded belief in the minds of some that beauty of architecture has been achieved in many instances at the expense of thoroughly practical utility. In formulating plans for a hospital it should be remembered that beauty is only skin deep, and that the prime object of the hospital is the efficient, economical care of patients coming to it. The increasing demands on the part of the public for greater free hospital facilities, together with the difficulties frequently experienced in securing the necessary funds to meet these demands, causes one to wonder, if, in the construction of the large modern hospital of today, we always realize the largest practical and efficient facilities possible for the expenditure involved. The hospital administrator engaged in planning buildings should duly consider the opinions and desires of the staff, but he will frequently be shocked by the unreasonableness thereof, both as to space desired and equipment asked for. It is then his duty and province to evaluate their demands and bring them into proper relation with the whole on the basis of modern medical knowledge and principles and methods of administration.

University Hospital.

THE TONSILS AS A HABITAT OF ORAL ENDAMEBAS

POSSIBILITY OF SYSTEMIC COMPLICATIONS OF ORAL ENDAMEBIASIS *

ALLEN J. SMITH, M.D.
PHILADELPHIA
WILLIAM S. MIDDLETON, M.D.
MADISON, WIS.
AND
M. T. BARRETT, D.D.S.
PHILADELPHIA

In connection with work recently carried on by Smith and Barrett in the pathologic laboratories of the University of Pennsylvania[1] indicating that the parasitic amebas of the mouth hold an important relation in the etiology of pyorrhea alveolaris or Riggs' disease, and that by the use of emetin (alkaloid) as an amebicide these organisms may be destroyed and the pyorrheal lesions cured, we have sought to determine whether these protozoa may not find their way also into the tonsils and there perhaps be of importance in determining or in maintaining certain of the inflammatory lesions of these structures, at least with or without associated systemic complications. To the present time only the first of these propositions can be said to be proved, that is, that these parasites actually at times involve the tonsils. The conditions of the tonsils of persons in whom they have been found infested, and the behavior of several positive cases with systemic complications after the administration of emetin, however, are decidedly suggestive and encouraging to continued investigation now in hand.

In the work of Smith and Barrett the endamebas encountered in pyorrhea pockets have almost invariably been of the species *Endamoeba buccalis* Prowazek, 1904 (probably identical with *Endamoeba gingivalis* Gros, 1849 and *Endamoeba buccalis* Steinberg, 1869); two of their cases to date being regarded by them as *Endamoeba kartulisi* Döflein, 1901. They are uncertain, but regard it not improbable that of the instances held primarily as *Endamoeba buccalis,* certain ones may represent a third, as yet unclassified species. These organisms have been long known, but have been hitherto uniformly held to be non-pathogenic parasites of the mouth, on the supposition that they do not penetrate the tissues, are merely surface habitants, and are found in normal as well as in pyorrheic mouths. Barrett in his report of their work records the uniform discovery of endamebas in the pus of pyorrhea pockets in forty-six patients, without exception; offers as controls seven mouths free (after careful dental examination) from pyorrhea, and free also of amebas; and records to the date of his report before the Pennsylvania Dental Society (July 1, 1914) thirteen cases of Riggs' disease treated with emetin either with complete cure or with marked progress toward recovery. Since then all of these patients have fully recovered and numerous additional cases have been collected showing the presence of endamebas in pyorrhea pockets and the effectiveness of emetin in their destruction and in the cure of the suppuration.

In the latter part of July, 1914, before the American Dental Society of Europe, in session at the time in Paris, Dr. Angelo Chiavero,[2] a dentist of Rome, in a paper devoted to the morphologic and systematic study of *Endamoeba buccalis,* records his invariable discovery of the parasites in twenty-two cases of alveolar pyorrhea, its frequent presence in the soft deposits on sound teeth not kept in good hygienic condition, its absence from carious dental cavities in active process of decay and its absence from hard tartar. In his conclusions, however, he states his belief that these organisms are of no pathogenic influence, but that he regards them, from the fact that they feed on bacteria, as adjuvants to autodisinfection of the mouth.

Still more recently Bass and Johns[3] of New Orleans have announced their discovery of these endamebas in eighty-five out of eighty-seven cases diagnosed as Riggs' disease which they have had the opportunity of examining, and declare the curative efficiency of emetin administered hypodermatically. The results which have been obtained from the use of emetin, whether employed locally or administered hypodermatically, constitute an appealing argument for the actual pathogenic importance of these protozoa, an argument short only of ideal proof by successful inoculation of pure cultures[4] and surely of equal significance to the old "therapeutic tests" with mercury and iodids for syphilis and with quinin for malaria.

When one realizes the readiness with which along with the purulent discharge these parasites may emerge from the pyorrhea pockets, and the favorable circumstances for their active and passive distribution over the surface of the oral mucous membrane and of the teeth, there is little reason for wonder and no strong force of argument in the fact that they are found on these surfaces. There is as little reason to hold the frequency of their occurrence as human parasites as an objection to their pathogenicity if one remembers that it is commonly held by the dental profession that pyorrhea alveolaris is, with the exception of dental caries, the most frequent disease which affects humanity and that with careful examination by competent dentists an overwhelming proportion of all persons applying for all sorts of dental affections are found to have in obvious or in less degree some suppurative peridental lesions. Even if trivial, these may be the habitat of amebas and the source of those found on the free surfaces. It would be as reasonable to contend that because the endamebas of dysentery are found in the dejecta they do not also penetrate the tissue of the colonic wall. The pyorrhea pockets may very properly be held the analogs of the ulcerous excavations found in the mucosa and submucosa of the colon in amebic dysentery; and, while it is equally true of both locations that the endamebas which are actually at a given moment on the surface of the mucous membranes are not at that particular time causing disease, each species in its place by penetrating into the tissue produces a suppurating excavation, a "pocket" or an ulcer. The precise rôle in each instance of associated bacteria cannot be asserted; but there is reason to suspect their conjoined importance and, too, an important symbiotic relation between the protozoa and the bacteria.

---

[3] Bass and Johns: New Orleans Med. and Surg. Jour., 1914, lxvii, 456.

[4] Smith and Barrett (personal communication) have succeeded in obtaining indifferent and always bacterially contaminated cultures on fresh egg albumin, but have not succeeded in isolating the amebas so as to make inoculation experiments practicable.

Believing that from their proximity to pyorrhea pockets and their favoring anatomic structure the tonsils might be invaded and form another habitat for these endamebas, we made a number of examinations of tonsils to determine their occurrence in these organs. In examining the tonsils for parasitic amebas, because of the difficulty occasioned by want of technical skill in obtaining from these organs a proper amount of material for examination, the search was restricted at first to freshly excised tonsils, the examination being made directly in the operating room as quickly as the tonsils were removed. All the tonsils thus examined were removed by Dr. Ralph Butler of Philadelphia, to whom we wish to express our feelings of indebtedness. The excised tonsil was squeezed to discharge the more superficial contents of the crypts; and after this had been removed, by firmer pressure the deeper contents of the crypts and perhaps some of the interstitial juices were forced to the surface and examined on a warm slide, diffused in a small drop of warmed normal saline solution. Seventeen cases were thus examined, five of the number showing motile amebas of the type of *Endamoeba buccalis* Prowazek, and regarded by us as this organism. In the material obtained from a sixth case an ameboid type of cell, with multiple long slender almost filiform pseudopodia composed of clear material, and with a granular body roughly measuring 20 micromillimeters in diameter, non-vacuolated and with a small and clearly visible body regarded as the nucleus, was found. It was not unlike *Amoeba gracilis* (a form once encountered by one of us in a subphrenic abscess). No motility could be determined, however, and while it is believed to have been an ameba, uncertainty is acknowledged and the case is not included in the list of positive tonsillar infestations. All of these seventeen cases were instances of some type of chronic tonsillitis, usually with tonsillar hypertrophy. The tonsils of the five persons in whom these organisms were demonstrated were all large, with pouting crypts; and were removed from young persons presenting the usual local and general symptoms of chronic tonsillitis with irregularly occurring exacerbations. The cases were not followed up beyond the point of determination of the parasitism, since, at the time, the establishment of this as a fact was the prime purpose in hand.

During the same time attempts were made, but in no instance with success, to obtain material from the tonsils *in situ* by scraping out the contents of enlarged crypts with a suitable pointed instrument. Later, however, with a fine pointed glass pipet to which was attached a strong suction bulb it was found comparatively easy to withdraw a small amount of semifluid material from the depths of the crypts, sufficient for microscopic examination. The tonsils are practically insensitive to the operation, and the point of the pipet may be introduced without discomfort into the crypts to such a depth that when suction is applied numerous red blood-cells are withdrawn in the viscid fluid which enters the lumen of the tube, indicating that more than mere cryptal contents are obtained. This is placed, with or without dilution, in warmed normal saline solution, on a warmed slide, covered, and examined without further preparation for the moving amebas. Permanent preparations may of course be made by fixing the film, preferably in warm Schaudinn solution, and staining with Giemsa's stain or with iron hematoxylin; but for diagnostic purposes the recognition of the moving parasites is advantageous and satisfying. We have thus far not found the organisms in this tonsillar material in numbers comparable to those ordinarily noted in the material from pyorrhea pockets, but believe that with better methods of withdrawal of material they will be found more frequently and in larger numbers.

Riggs' disease has for years been suspected of primary relationship to various systemic disturbances, including particularly certain chronic or recurrent arthritic affections, and possibly, too, some of the anemias of obscure origin and degenerative lesions of various parenchymatous organs; and even greater suspicion, amounting almost to certainty, has attached to tonsillar affections in relation to such systemic complications. Following these ideas, which are essentially those of Hunter[5] and others, the possibility of more generalized influences must necessarily occur, the effects of either the endamebiasis or of the associated bacteria, or both. Direct extension of the inflammatory processes, or lesions due to metastasis by lymphatic or hemic convection, or due to the effects of swallowed or absorbed toxic products are, logically, at least to be thought of.

In several instances in the series of cases treated for pyorrhea by Dr. Barrett, there has been noted, after the cure of the pyorrhea, the disappearance of symptoms of gastric and intestinal disorders. Similar experience has been related to us by several dentists following emetin medication; and while perhaps in a few cases this may be due to the happy effect of a coincidence of pyorrhea and amebic dysentery (as in a case communicated by Dr. F. C. Narr of Philadelphia to us), this explanation can be accepted only in exceptional instances. It would rather suggest that the cure of the oral lesions has diminished the bacterial and other poisons which previously had been swallowed and had been causative of some grade of gastritis.

During the latter part of the summer in the wards of Dr. B. F. Stahl in the Philadelphia General Hospital six cases of chronic arthritis were examined, in four of which endamebas were discovered in material thus obtained from the tonsils. These were all adults.

CASE 1.—A white male patient had been recently admitted with a history of arthritis of ten months' duration, in one knee, an ankle and both shoulders. The tonsils were not especially enlarged, but showed prominent crypts with the tissue immediately surrounding them turgid, boggy and red, giving the crypts a pouting appearance. There was a history of recurrent, mild, apparently causeless sore throat. Under treatment with salicylates the conditions in the tonsils and joints cleared fairly promptly; and two examinations thereafter failed to show the presence of endamebas, which at first were readily encountered along with numerous spirochetes and bacteria.

---

[5] Hunter: Brit. Med. Jour., Nov. 19, 1904.

Case 2.—The patient, a white man, was admitted with a subacute arthritis of supposed Neisserian origin, affecting the right ankle. The tonsils were of the same type as in the preceding case, and material removed by pipettage showed occasional amebas. The case cleared up symptomatically on ordinary treatment in about four days, succeeding which period three examinations on different days failed to show the persistence of any endamebas.

Cases 3 and 4.—Both patients were afflicted with chronic arthritis, but presented no appreciable tonsillar lesions. Material taken by pipettage from the retrotonsillar space in front of the faucial pillars revealed no endamebas in either. (We regret that tonsillar puncture was not performed for obtaining material, as we believe that the proper material, suggested by the blood-cells always obtained in the pipet, is really not merely of cryptal but also of interstitial source.)

Case 5.—A white woman, with typical rheumatoid arthritis, with the small joints of the hands and feet, the joints of the jaw, elbows, ankles and knees and of the spinal column affected, gave a history of recurrent sore throat. Her tonsils were fibroid; the tonsillar tissue on the right side just anterior to the posterior pillar red and beefy in appearance. Amebas have been found repeatedly from material from the latter situation.

Case 6.—A white man with chronic arthritis (involving both knees, ankles, wrists and elbows, and the small joints of the hands and feet) had cryptal enlargement in both tonsils, with a deep red boggy appearance of the pericryptal tissue of the tonsils, this more marked on the left than on the right side. Amebas were readily found in the material withdrawn from the tonsils.[6] Originally this man had an attack of acute articular rheumatism eighteen or twenty years ago, with persistence of subacute symptoms for six months afterward. In the interim, while suffering from occasional twinges of pain in various joints (never disabling) he was free from acute symptoms until four months prior to his present admission to the hospital; and at irregular periods had a recurrent sore throat usually without appreciable cause. In the spring of the current year he developed a septic thrombophlebitis of the right internal saphenous vein for which he was treated in the Philadelphia Hospital, being kept in bed almost continuously for six or eight weeks. He was thereafter discharged from the hospital; but until his readmission about eight weeks later he was never free from pains in his joints, although able to move about without much difficulty, but with many of his joints showing permanent enlargement. He was readmitted to the hospital in a state of intoxication and was assigned to the "drunk ward," where he soon developed an acute exacerbation with arthritic involvement as stated above, and with moderate swelling and redness evident about many of the involved joints. For a week he was actively treated with sodium salicylate and bromid of sodium, but without appreciable effect on the arthritic condition. At this time endamebas were found in the tonsils (and too in pyorrhea pockets); and from August 6 the patient was given thrice daily 1/6 grain of emetin hydrochlorid (by mistake by the mouth, although ordered hypodermatically). August 9 he was entirely free from pain in the joints and from the redness and swelling except in the knees. From the last date he was given 1/3 grain of emetin daily hypodermically, and on August 12 he was free from all acute arthritic symptoms, but with persisting enlargement of the joints. Thus improved he was discharged.

Case 7.—A somewhat similar case was communicated to us by Dr. Gibson Smith of the intern staff of the Murray Hospital of Butte, Mont. The subject, a white adult, a miner, had had subacute arthritic symptoms involving the joints of the neck, elbows, wrists, fingers, knees, ankles and toes for five or six months continuously, with irregular exacerbations through this period. He had had his upper teeth removed fifteen years before, presumably because of pyorrhea, and has had pyorrhea about the lower teeth at least ever since. Numerous motile endamebas were found by Dr. Smith in pus from the pyorrhea pockets. No examination of material from the tonsils was made, these organs appearing normal grossly. The pyorrhea was treated locally with emetin hydrochlorid, and in addition the drug was administered hypodermatically. Within four days the gingival suppuration had ceased and the amebas could no longer be found in scrapings from the pockets; the joint symptoms had subsided and the patient was able to return to his employment for which he had previously been incapacitated more or less of the time. No report has been received to indicate whether or not the improvement has continued.[7]

Two other cases, one referred through the kindness of Drs. Krumbhaar and Gerhard from the medical dispensary of the Pennsylvania Hospital, the other a patient in the medical ward of the University Hospital examined by permission of Dr. Stengel, have been found to have amebic oral infestation.

Case 8.—The first of these, A. A., a white woman, aged about 40 or 45, was regarded by the dispensary physicians as having chronic toxic arthritis, and had been referred to the throat dispensary of the hospital, where it was advised that removal of one of the tonsils be performed because of a diffuse interstitial tonsillitis. Endamebas were found in pyorrhea pockets about several of her teeth, and in the affected tonsil. Emetin treatment was suggested for trial; but difficulty in obtaining the drug for use in the dispensary postponed for several weeks its employment, and no report has thus far been afforded.

Case 9.—The second case, that of A. R., a white woman in Dr. Alfred Stengel's wards in the University Hospital, presented the usual features of long-standing arthritis deformans. She was found to have a marked case of pyorrhea with endamebas in the pockets; but no parasites were found in the tonsils. Emetin was to have been used in the case, but on trial caused an unpleasant nausea and it was at once suspended.

In the original series of cases reported by Dr. Barrett as treated by local administration of emetin hydrochlorid for pyorrhea there was a young white woman with a marked but unstudied anemia, poorly nourished and in a depressed condition of general health. Since her recovery from the pyorrhea, a matter of about three months, she has acquired an excellent color, has added 15 pounds in weight and is now in excellent general condition. This case suggested the possibility that some of the obscure anemias, especially those suspected of being of hemolytic origin, might find their explanation in oral endamebiasis. Thus far we have had the opportunity of examining the mouths in three cases regarded as pernicious anemia and in all three have found *Endamoeba buccalis* in the gums and in one of the three also in the tonsils. All three of these patients have been receiving treatment with other remedies, and it is quite impossible to know whether the emetin applied locally and hypodermatically to two of them has had any influence or not. One of the two, improving under sodium cacodylate and iron, has improved continuously and apparently especially after local treatment of his pyorrhea and hypodermic administration of emetin hydrochlorid. A less marked but distinct temporary improvement was noted in the second, although at present the blood-picture has receded; here, too, the emetin was only incidental to treatment with sodium cacodylate and iron citrate.

---

[6] The rapid hemolysis of a freshly englobed red blood-cell in one of these endamebas is noted in this case, and is of interest; disappearing without fragmentation by solution in the course of five minutes. The same phenomenon has been seen in endamebas from pyorrhea pockets by Smith and Barrett.

[7] Reported Oct. 15, 1914, that after recurrence of arthritis with well-marked redness and swelling on September 16, an intramuscular injection of 2 grains of emetin hydrochlorid was promptly followed by disappearance of all arthritis symptoms, without any return to date of report.

We freely acknowledge that the scant data here presented can in no wise be interpreted as proving that oral endamebiasis is surely a factor of generalized intoxication in the production of arthritis or anemia. We believe, however, that the positive finding of the parasitism in connection with these conditions and the favorable features mentioned as met after administration of emetin in these few isolated cases are sufficiently suggestive to warrant further trial. In study of the possible relation it would be illogical to suppose that the toxic states determining either the arthritides or the anemias must either entirely or always be due to the oral condition; at best, if there be a relation, that can be true only in individual cases. Efforts to determine a relationship are sure to fail frequently, and failures are bound to be recorded (even if we are correct in our suspicions) until sufficient knowledge and experience are had to select properly, directly or by elimination, the appropriate cases. It is illogical to even suspect that, granted the existence in an individual of oral endamebiasis, there must necessarily be systemic complications, or that such complications must be of uniform character. Much must depend on the local circumstances governing absorption, and much, too, must depend on the number and type of associated bacteria. Whatever other relation may obtain between the amebas and the accompanying vegetable micro-organisms, one may be certain that the amebas feed largely on the latter; and in this bacterial phagocytic action they doubtless set free from this and from that organism different endotoxins. Doubtless bacterial toxins thus originating play a more important part than do toxins from the amebas themselves, if there be amebic toxins; and the end-results of toxic absorption are sure therefore to vary, now manifesting as hemolysis, now as cellular degenerations or necroses of fixed tissues, now as inflammatory changes as of synovial or serous membranes.

CROTALIN IN EPILEPSY *

C. L. JENKINS, M.D., and A. S. PENDLETON, M.D.
First Assistant Physician and Clinical Pathologist, Respectively, State Hospital
RALEIGH, N. C.

On account of the wide publicity given through the lay press to the supposedly wonderful results to be obtained from the use of crotalin in the treatment of epilepsy, we feel that we owe it to the profession to present to it the results obtained from this treatment at the Epileptic Colony at the State Hospital at Dix Hill.

First, we wish to state that this treatment has been given under and by the direct advice of Dr. Thomas J. Mays, one of its chief advocates, and to say further that his instructions have been faithfully carried out.

The advocates state that the principle on which this treatment depends is the fact that crotalin decreases the coagulability of the blood, and they assert that the coagulability is increased in epilepsy. We wished to confirm or refute this and very readily did so by making use of a Boggs coagulometer, which was first carefully tested out on normal blood at a temperature of from 60 to 65 F., the temperature at which the abnormal blood was tested. The mean coagulation time for this particular instrument was 6 6/17 minutes. The mean coagulation time for the blood of nine epileptics who had received no crotalin was 12 7/9 minutes. The mean coagulation time for the blood of eleven epileptics who had received about forty doses of the remedy was 9 3/11 minutes, while the mean coagulation time of the blood of thirteen epileptics who had been given eighty or more doses was 7 4/13 minutes. These findings would indicate that the exact opposite to the assertions of the advocates is true, and this is further in accord with the well-known serologic principle that the injection of any foreign substance into the blood causes the formation of antibodies.

That this condition of the blood is exceedingly transitory seems probable, as in three patients who had taken no crotalin in three weeks (though they had previously received over one hundred doses) the mean coagulation time was 14 1/3 minutes.

In a more recent paper, Dr. Mays states that he uses crotalin on account of its pharmacologic effect, saying that its action is very similar to that of the cyanids. Let us hope that he is nearer right in this than in his former contention. We are afraid, however, that even this is not entirely true, as practically all of the patients assert that they get decided stimulation from the therapeutic dose of this drug, and the cyanids have never been accused of any such action.

CONVULSIONS DURING TIME OF OBSERVATION

Period	Dosage	Time	Number of Convulsions Men	Women	Tot.	Gr. Tot.
Three months before treatment	No crotalin	January ...	215	135	350	
		February ..	241	190	431	
		March	280	214	494	1,275
First three months of treatment	10 minims twice a week	April	277	267	544	
		May	333	286	619	
		June	231	246	477	1,640
Second three months of treatment	10 minims once a week	July	263	282	545	
		August	209	289	498	
		September .	244	260	504	1,547
Third three months of treatment	5 minims once a week	October ...	253	235	488	
		November .	250	233	483	
		December .	275	247	522	1,493
Three months' treatment discontinued	....	March	157	201	358	
		April	274	250	524	
		May	257	222	479	1,361

In poisonous doses it does cause convulsions—whether or not for the same reasons that the cyanids do—remains to be proved. He tells us that the homeopaths have been using snake-venom by mouth for many years for epilepsy and by inference we are led to suppose that he has been converted to "the hair of the dog is good for the bite" theory. In this dissertation he further attempts to explain the nature of epilepsy, with the usual result.

Differential blood counts in nineteen patients who had received from forty to one hundred doses showed a tendency to slight eosinophilia with a slight increase in mononuclears, with no apparent effect on the total number of leukocytes or on the red blood cells, nor did the hemoglobin seem to be affected. In two cases with abscesses the septic factor was present, as would be expected.

The drug is supplied in solution, 5 minims of which equals 1/100 grain, and the directions are to give it hypodermatically twice a week, beginning with 4 minims and increasing to 10. Later advices were to give no more than 5 minims. The hygienic and dietetic treatment was the same for these as for other patients.

To determine its effects on the number of convulsions, it was decided to record accurately every con-

---

* Read before the North Carolina Medical Society.

vulsion occurring during the three months preceding its use and to compare the number of these with the number occurring during the first, second and third periods of three months each while the treatment was being given, the doses being different in each of these periods, and further to compare this number with the number occurring during the three months after the treatment was stopped altogether.

The treatment was begun the last week in March, 1913, and forty-nine patients were treated. During January, February and March there were 1,275 convulsions. During April, May and June, the first period of treatment, when 10 minims were given twice weekly, there were 1,640 convulsions. During July, August and September, the second period of treatment, when 10 minims once weekly were given, there were 1,547 convulsions. During October, November and December, the third period of treatment, when 5 minims once weekly were used, there were 1,493 convulsions. The treatment was discontinued some time in February, 1914, and sterile water used in place of the venom so as to retain any psychologic effect there might be, and the number of convulsions during March, April and May was found to be 1,361. This would indicate that not only does the medicine not decrease the number of convulsions, but actually increases them and in direct proportion to the amount given.

As to the effect on the mental condition of the patient, there has been no more improvement in those taking crotalin than in those taking the usual treatment.

It is only fair to state that a large majority of the patients brought to the colony for treatment are in bad shape both mentally and physically, and that many of these improve markedly in these respects after they have had the usual treatment here, while quite a few have fewer convulsions, owing to the regular life, and careful hygienic and dietetic management, together with freedom from worry and irritation from the outside. This effect is obtained in spite of the fact that they get practically no bromids when compared with the amount they receive before admission.

As a result of our observation, it would appear therefore that:

1. The blood of epileptics is less coagulable than that of normal persons, and the coagulability is transiently increased by the use of crotalin.
2. The number of convulsions is increased by its use and in direct proportion to the amount used.
3. Its use seems to have no effect on the mental condition of the patient, all of which is absolutely contrary to the claims of the advocates of the treatment. Its use does, however, to a certain extent, satisfy the abnormal craving for medicine which all epileptics have.

Health as a Social Ideal.—The New Health, as a social ideal, signifies that in our day, because of our new knowledge, our new science of sanitation, our new conscience, our new spirit of brotherhood, our new democracy, our new social intimacy of understanding, we are coming to feel about the public health as our fathers have felt about religion, education, liberty and nationality. We are to feel that health is fundamental and inalienable, that it imposes sacred obligations, calls us to willing service, becomes the object of our constant concern, makes us ashamed of inefficiency, stupidity and graft, because they mean disease, raises us to a new level of brotherhood.—Edward T. Devine, *Journal of Outdoor Life.*

A COMPARISON OF THE WASSERMANN AND LUETIN REACTIONS IN 744 INDIVIDUALS

EDWARD B. VEDDER, M.D.
AND
WILLIAM B. BORDEN, M.D.
Captain and First Lieutenant, Respectively, Medical Corps U. S. Army
WASHINGTON, D. C.

The tests here recorded were performed at the U. S. Soldiers' Home at Washington, D. C., in the course of an investigation to determine the prevalence of syphilis in that institution.

The inmates of the Soldiers' Home are all discharged soldiers who have served twenty or more years in the army, or who have been discharged for some disability incurred in the service. Practically all of the inmates, therefore, suffer from some disability or chronic disease, and the great majority are well along in years, 80 per cent. being between the ages of 50 and 80. There are a fair number of cases of locomotor ataxia, and a considerable number suffering from circulatory disturbances, liver diseases, etc. Under such circumstances it might reasonably be expected that a large proportion of these men would show evidences of having suffered from syphilis. This was, therefore, considered an exceptionally good opportunity to test the relative efficiency of the Wassermann reaction and the luetin test.

Both tests were accordingly performed on as many men at this institution as possible. No selection of cases was made, but all the men in each building were taken in order.

The luetin was furnished by Dr. Hideyo Noguchi of the Rockefeller Institute. The luetin was injected according to the prescribed technic, and three readings were made at weekly intervals thereafter. Double plus was used to indicate a very severe reaction; plus to indicate a strong reaction; plus minus to indicate a slight reaction. Only the double plus and plus reactions were considered to be diagnostic of syphilis.

The Wassermann reactions were performed by one of us at the Army Medical School following the technic described by Captain Craig, M. C.[1] A human heart cholesterin antigen, prepared according to the method of Walker and Swift,[2] was used.

This antigen has been criticized lately by several workers, notably by Thomas and Ivy,[3] who state that many false positives have been reported following the use of this antigen. As it is not within the scope of this paper to discuss the technic of the Wassermann reaction, it will be sufficient to state here our belief that when this antigen is used with a proper technic, it will give no more false positives than other antigens. This opinion is based on 4,588 reactions that have been performed up to date in cases in which the history and clinical symptoms were available as a check, and out of this number of cases, we have so far had only two cases in which a false positive (double plus) has been returned. These were both cases of diabetes. The plus reaction is never considered diagnostic except as corroborative evidence in the presence of a history or physical signs indicating syphilis. We may add that possibly the reason Thomas and Ivy obtained so many false positives with the cholesterinized antigen was that they appear to have used it with only one unit of complement and amboceptor. Most workers have held that two units of complement and amboceptor should be used as a factor of safety. At any rate this was the system in which this antigen was used by Walker and Swift, and it is obviously unfair to the antigen to condemn it as giving false positives after cutting down the hemolytic system to half of that used by Walker and Swift. In our tests, the complement has always been accurately titrated and two units of both complement and amboceptor have been used.

The results of this examination are shown in Table 1.

TABLE 1.—RESULTS OF EXAMINATION

Reaction	++	+	±	—	Total
Wassermann	100	56	123	465	744
Per cent.	13.30	7.52	16.53	62.50	
Luetin	45	194	165	340	744
Per cent.	6.04	26.07	22.17	45.70	

Tables 2 and 3 bring out still more clearly the relation between the luetin and Wassermann tests.

TABLE 2.—COMPARISON OF WASSERMANN AND LUETIN TESTS

Wassermann	Luetin ++	+	±	—
100 ++ = ...	8	27	21	44
56 + = ...	6	16	13	21
123 ± = ...	8	26	29	60
465 — = ...	23	125	102	215
744	45	194	165	340

TABLE 3.—COMPARISON OF LUETIN AND WASSERMANN TESTS

Luetin	Wassermann ++	+	±	—
45 ++ = ...	8	6	8	23
194 + = ...	27	16	26	125
165 ± = ...	21	13	29	102
340 — = ...	44	21	60	215
744	100	56	123	465

From these tables it is evident that the Wassermann and luetin reactions do not give corresponding results. The plus reaction to the luetin test, as we read it, may undoubtedly be considered a positive reaction. The plus Wassermann, on the other hand, is very suspicious but not diagnostic unless confirmed by history or physical signs. But even if we count double plus and plus reactions as a positive indication of syphilis for both the Wassermann and luetin tests, and plus minus and negative reactions as negative, it is apparent that while by the Wassermann reaction, we have only 156 positive out of 744, or 20.82 per cent., by the luetin test we have 239 positives out of 744, or 32.11 per cent. The luetin test is, therefore, more delicate than the Wassermann as a routine test in the class of cases that we examined, or else it is giving a number of false positives. We are convinced that the former is the correct explanation from the accumulated experience of other observers as well as our own. We have performed the luetin test on a considerable number of persons in whom syphilis could be excluded and have never obtained a positive reaction. The great majority of the patients in this series who have a positive luetin reaction had some history or physical signs indicating syphilis.

It may further be seen that of 588 cases (465 — and 123 ±) negative by the Wassermann, 182, or 32.6 per cent., of the 588 cases were positive by the luetin test. While of the 505 cases (340 — and 165 ±) negative by the luetin test, 99, or 19.6 per cent., of the 505 cases were positive by the Wassermann. It is therefore clear, providing the results of both the luetin and Wassermann tests as we performed them are accurate and reliable, that these two tests complement each other to a certain extent. In other words, had we used the Wassermann reaction alone, and counted both double plus and plus reactions, we would have found 156 positive, or 20.8 per cent., of syphilis; if we had used the luetin reaction alone, we would have found 239 positive, or 32.1 per cent., of syphilis. But by using both tests, we find 338 positive (156 positive by Wassermann, 239 positive by luetin, minus 57 positive by both tests), or 45.4 per cent., of syphilis.

It is also interesting to note that there were only 57 cases, or 7.66 per cent., that were positive to both tests, while 406 cases, or 54.57 per cent., were negative by both tests, leaving 281 cases, or 37.76 per cent., that were positive by one test but negative by the other.

The latest estimation of the practical value of the luetin reaction by Noguchi[4] confirms the opinions previously expressed, that the Wassermann reaction is much more constant in primary and secondary cases, but that the luetin reaction gives a higher percentage of positives in tertiary, latent and treated cases. Our experience amply confirms the latter statement. Eighty per cent. of the men in this series were between 50 and 80 years of age, and when syphilis was present it was with rare exceptions in the tertiary or latent stages.

It is believed that the use of a cholesterinized antigen renders the Wassermann reaction more efficient, and that a number of undoubted syphilitics who give a negative reaction with other antigens will give a positive reaction with a cholesterinized antigen. But even if this be granted, it is apparent that in tertiary, latent and treated cases, the luetin test is considerably more efficient in detecting syphilis than the most efficient Wassermann reaction. A test of so much value would be of great assistance to the general practitioner, and it is to be hoped that some arrangement may be made whereby a supply of luetin may be made available for general use.

We wish to express our thanks to Dr. Noguchi for his courtesy in supplying us with an ample amount of luetin, and to Lieut.-Col. James D. Glennan, the surgeon at the Soldiers' Home, for the encouragement and cooperation which made this investigation possible.

---

The Medical Schools in Belgium.—The University of Louvain was founded in 1426 and ranked only second to Paris during the middle ages, but it was abolished by the French in 1797. In 1835 it was revived as a Roman Catholic institution. The medical department at the opening of the current year had seventeen professors, including the neurologist, A. Van Gehuchten, and two docents. The medical department of the University of Liége included fifteen professors and six docents. Familiar names on the list are the surgeon, von Winiwarter, Fraipont, Schiffers, Beco and Malvoz. The University of Brussels is the best equipped in Belgium, and among its twenty-five professors and thirty-one agrégés are the surgeon, Depage, who presided over the International Surgical Congress in New York last spring, and Bordet, whose research provided the basis for the Wassermann reaction, etc. The medical faculty of the University of Ghent numbers eighteen and includes Van Ermengem, sponsor of botulism.

THE DIAGNOSTIC VALUE OF THE SPHYGMOMANOMETER IN EXAMINATIONS FOR LIFE INSURANCE*

J. W. FISHER, M.D.
Medical Director of the Northwestern Mutual Life Insurance Company
MILWAUKEE, WIS.

Prior to 1907, little or no use was made of the sphygmomanometer except in clinical cases. Three years ago in a paper delivered before the Medical Directors Association, I said:

> No practitioner of medicine should be without a sphygmomanometer. He has in this instrument a most valuable aid in diagnosis. The sphygmomanometer is indispensable in life-insurance examinations, and the time is not far distant when all progressive life-insurance companies will require its use in all examinations of applicants for life insurance.

TABLE 1.—ACTUAL MORTALITY TO AUG. 1, 1913, AS COMPARED WITH THE EXPECTED, ACCORDING TO THE ACTUARIES' TABLE AND MEDICO-ACTUARIAL TABLE OF MORTALITY IN CERTAIN BLOOD-PRESSURE CASES *

Years	Number of Lives	Actual Deaths	Expected Deaths (Actuaries' Table)	Per Cent. (Actual to Expected)	Expected Deaths (M.-A. Table)	Per Cent. (Actual to Expected)
1907	216	10	19.625	50.96	13.486	74.15
1908	651	31	53.760	57.66	36.386	85.20
1909	957	17	59.302	28.67	38.889	43.71
1910	837	27	39.639	68.11	25.205	107.12
Totals .	2,661	85	172.326	49.33	113.966	74.58

* Mortality of accepted risks with systolic blood-pressure of 140-149 mm. Hg with an average of 142.43 mm. Hg—all ages.

To-day this prediction is practically fulfilled, and no up-to-date practitioner is without this very valuable aid in diagnosis, much of which has been due to the requirements of life-insurance companies in insisting on their examiners using the sphygmomanometer in examinations for life insurance. I have received hundreds of letters thanking me for insisting on its use in examinations for the company and testifying to its very great value in private practice.

TABLE 2.—MORTALITY OF ACCEPTED RISKS WITH SYSTOLIC BLOOD-PRESSURE OF 150 MM. HG AND OVER: AVERAGE 152.58 MM. HG—ALL AGES

Years	Number of Lives	Actual Deaths	Expected Deaths (Actuaries' Table)	Per Cent. (Actual to Expected)	Expected Deaths (M.-A. Table)	Per Cent. (Actual to Expected)
1907	87	8	8.154	98.11	5.726	139.71
1908	212	17	18.812	90.37	13.023	130.54
1909	161	4	12.173	32.86	8.357	47.86
1910	65	4	3.660	109.29	2.419	165.36
Totals .	525	33	42.799	77.10	29.525	111.77

The use of the sphygmomanometer demonstrates in many cases that a supposedly normal person may have an abnormally high blood-pressure and present no symptoms or pathologic changes discoverable by any of our present methods of diagnosis, thereby suggesting a careful study of the case before any symptoms of disease are discoverable, thus rendering the sphygmomanometer a valuable and indispensable aid in diagnosis. Clinicians for some time considered a blood-pressure of 180 mm. Hg as of little significance; now a pressure of 160 mm. is regarded as one that calls for further study of the case, while the statistics presented herewith show that a blood-pressure of 150 mm. Hg gives a higher mortality than an average risk accepted by conservative life-insurance companies, and this covering a period of only a comparatively few years. I am firmly of the opinion that a persistent blood-pressure of 15 mm. Hg above the average for the age of the applicant should at least excite suspicion and call for further careful and painstaking investigation.

TABLE 3.—MORTALITY OF APPLICANTS REJECTED WITH AVERAGE SYSTOLIC BLOOD-PRESSURE OF 161.44 MM. HG—ALL AGES

Years	Number of Lives	Actual Deaths	Expected Deaths (Actuaries' Table)	Per Cent. (Actual to Expected)	Expected Deaths (M.-A. Table)	Per Cent. (Actual to Expected)
1907	46	14	4.816	290.70	3.443	406.62
1908	118	18	10.817	166.40	7.565	237.94
1909	213	22	15.464	142.27	10.509	209.34
1910	221	12	13.250	90.57	8.973	133.73
1911	318	7	10.809	64.76	6.707	104.37
1912	668	9	10.295	87.42	5.589	161.03
1913	386	1	1.749	57.18	.904	110.62
Totals .	1,970	83	67.200	123.51	43.690	189.97

The Northwestern Mutual Life Insurance Company, in the year 1906, in order to test the diagnostic value of the sphygmomanometer in examinations for life insurance, made use of the instrument in its examination of applicants for insurance at its home office. The results were such that in August, 1907, it was deemed advisable to require its use by our examiners in the field who possessed an instrument or could be induced to secure one. The result was that in a number of the larger cities we were enabled to secure its use in examinations for the company. By the first of the year 1912, 90 per cent. of the examiners of the company were using the instrument in their examination of applicants for insurance. At the present time there are very few examiners of the company who do not possess an instrument.

TABLE 4.—MORTALITY OF APPLICANTS REJECTED WITH HIGH BLOOD-PRESSURE (AVERAGE 164.77 MM. HG) AND ONE OR MORE OTHER IMPAIRMENTS

Number of Lives	Actual Deaths	Expected Deaths (Actuaries' Table)	Per Cent. (Actual to Expected)	Expected Deaths (M.-A. Table)	Per Cent. (Actual to Expected)
888	43	32.422	132.63	21.409	200.85

The blood-pressure was required by the company (except in special cases) only at ages from 40 to 60 (the company does not insure persons whose insurable age is over 60). Since November, 1911, it has been required at all ages and irrespective of amount of insurance applied for.

Our company has rejected 405 applicants, up to June 1, 1914, under the age of 40, who had a persistent blood-pressure of 15 mm. or more above the normal for their age, without any other impairment recorded on the blank, and 1,036 (ages 40 to 60), without any other impairment. In my opinion, the results fully demonstrate the value of the use of the sphygmomanometer in examinations for life insurance on applicants under the age of 40. Dr. Cabot[1] makes the statement that "slight increase of systolic blood-pressure is (fortunately for our diagnosis) rarely encountered. As a rule, if we find the blood-pressure high it is very high (160-250 mm. Hg) and not in the more dubious immediate regions (140-160 mm. Hg)." He undoubtedly refers to clinical cases only—persons who are ill and consult physicians for relief. They are not seeking life insurance. The class of cases encountered by the life-insurance examiner are those who have not as yet reached that stage. They suppose they are normal, believe they are in good health, and are seeking life insurance for the protection of their families. We frequently encounter men who are running a very high blood-pressure who declare they are feeling perfectly well and who consider themselves normal in every respect.

---

*Read before the American Association of Medical Examiners at Atlantic City, June 22, 1914.

TABLE 5.—IMPAIRMENTS RECORDED ON APPLICATIONS AT TIME OF MEDICAL EXAMINATION OF THE 888 CASES RECORDED IN TABLE 4

Arteriosclerosis Atheroma	Heart Murmur	Heart Hypertrophy	Albumin and Sugar	Albumin in Urine	Sugar in Urine	Albumin and Casts	Casts in Urine	Nervous Symptoms	Prostatic Disease	Miscellaneous	Total
109	216	53	15	259	37	21	12	30	16	120	888

By reference to Table 1, it will be seen that the company accepted 2,661 risks in the years 1907-1910, with an average blood-pressure of 142.43 mm. Hg at ages 40 to 60, and that the mortality is about the same as the general average mortality of the company for the same period, while Table 2 shows 525 risks accepted in 1907-1910, with an average blood-pressure of 152.58 mm. Hg (an increase of practically 10 mm. Hg blood-pressure over the foregoing), showing a mortality of over 30 per cent. in excess of the general average mortality of the company.

TABLE 6.—MORTALITY OF APPLICANTS REJECTED WITH HIGH BLOOD-PRESSURE ONLY (AVERAGE 159.90 MM. HG)

Number of Lives	Actual Deaths	Expected Deaths (Actuaries' Table)	Per Cent. (Actual to Expected)	Expected Deaths (M.-A. Table)	Per Cent. (Actual to Expected)
1082	40	34.778	115.02	22.281	179.53

Table 3 shows a mortality on 1,970 applicants rejected with an average blood-pressure of 161.44 mm. for the years 1907 to Aug. 1, 1913, with a mortality of 190 per cent. of the medico-actuarial table, which is considerably more than double the average mortality of the company. Table 6 is a record of 1,082 applicants rejected with no other impairment recorded on the blank at the time it was received at the home office. These had an average blood-pressure of 160 mm. Hg. All of these persons would have been granted insurance, with a mortality of more than double the mortality expected, had it not been for the high blood-pressure.

TABLE 7.—IMPAIRMENTS SUBSEQUENTLY DISCOVERED OR DEVELOPED IN THE 1,082 CASES RECORDED IN TABLE 6

Arteriosclerosis Atheroma	Heart Murmur	Heart Hypertrophy	Albumin and Sugar	Albumin in Urine	Sugar in Urine	Albumin and Casts	Casts in Urine	Nervous Symptoms	Prostatic Disease	Miscellaneous	Total
14	29	6	6	136	8	91	38	8	1	18	355

Number of Lives	Actual Deaths	Expected Deaths (Actuaries' Table)	Per Cent. (Actual to Expected)	Expected Deaths (M.-A. Table)	Per Cent. (Actual to Expected)
355	15	12.600	119.05	8.184	183.28

It should be stated that the company's average mortality is only 80 per cent. of the medico-actuarial table. The mortality in connection with the number of deaths which have occurred since August last, to date, in Tables 2 and 6, has not been computed, as it was found that it would not materially change the ratio. Five additional deaths have occurred in Table 2 and twelve additional in Table 6.

TABLE 8.—MORTALITY OF APPLICANTS REJECTED UNDER AGE 40—HIGH BLOOD-PRESSURE ONLY (AVERAGE 151.19 MM. HG)

Ages					Total	Actual Deaths	Expected Deaths (Actuaries' Table)	Per Cent. (Actual to Expected)
Under 20	20 to 25	25 to 30	30 to 35	35 to 40				
6	43	56	52	84	241	2	2.108	94.88

We have received but little diagnostic value in our work from the low pressure. Occasionally a low blood-pressure with a marked tuberculous family record leads us to decline a risk. We are, however, tabulating the risks accepted with a pressure of 100 mm. or less. We seldom insure a risk with a reading below 85 mm. Hg.

TABLE 9.—IMPAIRMENTS SUBSEQUENTLY DISCOVERED OR DEVELOPED IN THE 241 CASES RECORDED IN TABLE 8

Arteriosclerosis Atheroma	Heart Murmur	Heart Hypertrophy	Albumin and Sugar	Albumin in Urine	Albumin and Casts	Casts in Urine	Miscellaneous	Total
1	6	1	1	36	12	5	1	63

The same may be said of the diastolic pressure. We record it, however, in our examinations at the home office and require it of most of our examiners in the larger cities. As to what diagnostic or prognostic value may be attached to it, the future will reveal when our data are tabulated.

---

[1] Cabot: Physical Diagnosis, Ed. 5, 1912.

The mortality on the rejected risks as shown in the tables is undoubtedly much lower than the exact figures would show, were it possible to secure a record of all deaths. When the risk is not insured in this or other companies, we must depend on the solicitor and medical examiner to notify the company of the death of those risks which we rejected with a high blood-pressure.

The blood-pressure should be taken with the person in a sitting posture, with the arm resting on a table or other convenient rest, which will relax the muscles, at the completion of the applicant's declaration, and before the physical examination is begun, and again after the physical examination is complete. At least two, or better, three readings should be made at each test, and the average of all recorded on the blank.

TABLE 10.—CAUSES OF DEATH IN RISKS ACCEPTED (TABLE 2) AND RISKS REJECTED (TABLE 3)

	*Accepted**	*Rejected†*
Anemia, pernicious	..	1

41-45	6,740	866,518	128.56
46-50	4,471	583,795	130.57
51-55	2,371	313,282	132.13
56-60	1,100	148,261	134.78
Totals	19,339	2,492,968	128.91

*Compiled from 15,014 records of *this company* and 4,325 records of the Mutual Benefit Life Insurance Company.

Many of our examiners furnish us with both the palpatory and auscultatory readings. A difference of about 6 mm. higher in the latter method will be shown.

A high blood-pressure is found in about 6.5 per cent. of all applicants declined for insurance by the company.

"The Partisan of Truth Alone."—I avow myself the partisan of truth alone; and I can indeed say that I have used all my endeavors, bestowed all my pains on an attempt to produce something that should be agreeable to the good, profitable to the learned and useful to letters.—William Harvey.

THE NEUROLOGIC EXAMINATION OF MENTAL CASES *

JULIUS GRINKER, M.D.
CHICAGO

At this moment when the light of rational medicine is beginning to penetrate into the darkest corners of psychiatry, when chemical and biologic laboratories are uniting to displace the new psychosexual philosophy, it is most timely to make a plea for the thorough physical examination of the mentally afflicted. To just the extent that one whiles away precious time in deciphering dreams and reveling in the free associations of interesting neurotics, does one fail to learn all that can be known of a patient's physical constitution. If we are to achieve therapeutic and diagnostic success, the physical investigation of the insane must receive at least as much attention as, for instance, the devotee of the new psychology gives to psychanalysis.

That even competent observers may occasionally fail to recognize true neurologic conditions has been conclusively shown by E. E. Southard, who analyzed sixty-one cases in which the diagnosis of general paresis was made, forty-one of which were considered clinically certain and agreed to by all of the staff members at the Danvers State Hospital, while six were cases that had been wrongly diagnosed, the essential histologic features of general paresis having been absent. In place of these he discovered the changes of meningomyelitis, subcortical encephalitis, tabes with non-paretic cerebral disease, arteriosclerotic brain disease with involvement of the cerebellum, and cerebellar sclerosis. Instances abound in the literature and the unpublished cases are even more numerous—in which competent men have missed the neurologic diagnosis in a supposedly mental case, because no importance was attached to what seemed to them insignificant neurologic symptoms. It appears that in those cases the mental picture had completely overshadowed the neurologic aspect.

Though it is possible for even the most skilled examiner to mistake a neurologic disease for a case of frank insanity, the mistaken diagnoses are usually made by those who neglect the neurologic examination entirely. Of prime importance is it, therefore, to keep in mind the necessity for these examinations in all forms of mental disease. Since a neurologic examination has become part of the routine examination of every new arrival to an institution for the insane, it may appear unnecessary to plead for one. But every one who has had the privilege of witnessing such institution examinations can testify to their incompleteness, and these are not infrequently the only examinations made of the patient during his entire stay at the hospital. Unfortunately, the record made at a patient's entrance is seldom again referred to for the purpose of making additional notations.

The important organic nervous diseases not infrequently mistaken for insanity are brain tumor, cerebral arteriosclerosis, syphilis and non-specific vascular brain disease. Of the so-called functional nervous disorders not rarely diagnosed as insanity in private practice may be mentioned drug addictions, postinfectious and post-traumatic deliriums, and the psychoneuroses.

An error most humiliating to the physician and fraught with possible harm to the patient is the mistaken diagnosis of insanity in a case of brain tumor. Even after a thorough examination one may overlook the mental symptoms of a case of brain tumor, but it is next to impossible to give a patient a neurologic examination and then to diagnose a case of brain tumor as one of insanity. Knapp of Boston, in his statistical review, "The Mental Symptoms of Cerebral Tumor," informs us that not infrequently patients who were considered only insane have died from brain tumor. "The mental syndrome during life was so pronounced," says he, "that neurologic symptoms had been overlooked, until the post-mortem examination revealed the presence of neoplasm." Of the 104 cases from the literature which he had collected, there were mental disturbances sufficiently marked to attract attention in seventy-nine, a trifle over 75 per cent. of the cases. Schuster of Berlin, from a similar study of 775 cases culled from various sources, found a condition of simple mental weakness, dulness, somnolency and dementia in 423 cases, while 352 cases presented some active symptoms of mental disorder, among which he mentions those of general paresis, chronic paranoia, melancholia, Korsakoff's psychosis, hallucinatory delirium, circular states, mental weakness with excitement, senile dementia, and a number of minor types of insanity. In these cases it was noted that mental symptoms were more prevalent in left-sided brain tumor and that the larger the growth, the more pronounced were the symptoms. Further, he believes that tumors situated in the corpus callosum and frontal lobes are capable of producing mental symptoms which have a close resemblance to simple dementia. Tumors presenting the syndrome of general paresis with or without the delusions of grandeur have also their probable localization in the frontal lobes. Though some authors dispute the view that the frontal lobes are the seat of the higher psychic functions, the majority still favor this view, while it is generally admitted that the frontal lobes are not the only psychic centers. Since Monakow has so plausibly explained many of the otherwise inexplicable somatic brain symptoms by the theory of diaschisis, we may reasonably assume that coordinate intellectual function is likewise conditioned by the harmonious cooperation of several widely separated centers in the brain, each of which is capable, when diseased, of throwing out of commission the entire mental machinery. Thus, it appears that the occipitotemporal region, the zone of language, and the corpus callosum constitute important contributory streams to the higher mental life which has its fountain head in the frontal lobe.

---

* Read before the joint meeting of the Chicago Neurological Society and the Illinois State Hospital Society, Jan. 29, 1914.

This simple enumeration of the variously localized brain tumors capable of simulating true insanity may suffice to impress one with the importance of making careful search for the well-known tumor syndrome in every case of supposed insanity.

To mistake Korsakoff's psychosis for general paresis or confusional insanity is easy; but to commit this error after an examination of the reflexes, sensation and motion, is almost unbelievable.

That vascular brain disease, before and after the insult, is capable of producing the most manifold symptoms, some of which mimic the well-known syndromes of the classical psychoses, is familiar to all. To take the blood pressure, examine the urine and inspect the retinal vessels is equivalent to avoiding some hard falls.

With the advent of salvarsan therapy the differentiation between the non-specific psychoses and those produced by brain syphilis has assumed practical importance. Thanks to the laboratory which has furnished us the "four reactions" and a gold-sol test, we are now in a better position to diagnose syphilitic nervous disease than formerly, but we must be ever mindful that the laboratory still is, and probably always will remain, the handmaid of the clinician.

In referring to the functional disorders which occasionally assume the mask of true insanity, we may state that the drug-addictions, including alcoholism, easily lead the rest. Mention must also be made of the postinfectious and posttraumatic deliriums as well as the psychoneuroses.

In a recent paper Alfred Gordon states that from his study of 171 cases he came to the conclusion that the chronic forms of opium and cocain poisoning resemble many forms of insanity. He finds that "some cases simulate melancholia, mania, manic-depressive insanity and even catatonia, though none of them give the typical pictures of these psychoses. Among the well-recognized symptoms of those drug-intoxications are hallucinations of sight and hearing. While the delusions of this type are mostly transient, fleeting and fragmentary in character, at certain periods of their evolution they may assume the form of systematized delusions, reinforced by hallucinatory images. Thus, some of them may present a picture closely allied to paranoia. A characteristic symptom is the gradually oncoming dementia which develops insidiously and increases with years, until a complete psychic decrepitude is established."

Though many of the insanities have alcoholic excess as an important contributing causative factor, there are several types of psychoses which appear to be produced entirely by chronic alcoholism. Because of their resemblance to other well-known forms of insanity, they are spoken of as alcoholic paranoia, pseudoparesis, etc. In most cases the careful search for somatic evidence, past or present, of the stigmata of chronic alcoholism will lead to a correct diagnosis, while the disregard of a physical and neurolgic examination often avenges itself by complete failure. As the ultimate prognosis of even moderately advanced alcoholic psychoses is infinitely better than for instance that of dementia praecox, paranoia or arteriosclerotic dementia, the timely recognition of the alcoholic character of a psychosis is an advantage of no mean value.

Most gratifying to the clinician are the cases of acute insanity following trauma or infection, provided a correct etiologic diagnosis has been made. Not a few of these patients can be treated at home. Much damage both to patient and physician has resulted from mistaking such curable psychoses for the incurable ones. Likewise many a case of psychasthenia, hysteria and even neurasthenia has been diagnosed as insanity, because of the examiner's predilection for short cuts.

In conclusion I may be permitted to repeat Charcot's statement that more mistakes are made by not examining than by not knowing.

Heredity.—An infection, an habitual intoxication of the parents, a maternal disease during pregnancy, can determine perversion of development, which though so slight and uniform as to be quite unobservable at birth, comes to the surface with the progress of years in the shape of unexpected failures of certain fundamental functions of intelligence, of eccentricity of character and of perversion.—Lugaro, Problems in Psychiatry.

BLINDNESS, CAUSED BY OPHTHALMIA NEONATORUM *

RICHARD J. TIVNEN, M.D.
CHICAGO

The part played by ophthalmia neonatorum in producing blindness is a sadly conspicuous and leading one. It enlists our sympathetic interest because its victims are, in the vast majority of instances, the "little ones," who are powerless to prevent its occurrence and powerless also to make known the early manifestations of a disease which is destroying their sight. In consequence of its ravages, the lives of these defenseless unfortunates are blighted irrevocably, and they are forever consigned to a future of unending darkness. No writer can be charged with unseemly reiteration, no medical tongue accused of boresome repetition, no matter how often or how insistently he dwells on this painful, humiliating truth, namely, that the vast majority of these little ones could have been spared their sad affliction if only the simplest elementary precautions had been observed at the proper time.

Statistics are numerous, indicating the frequency and the proportion of blindness caused by the disease. A study of these, collected by different observers, warrants the conclusion that one-eighth of blindness from all causes is due to this disease, and one-fourth of the blindness among children is attributable to the same cause.

A comparison of statistics from different sources is shown by Tables 1 to 6.

The "Special Reports on the Blind and the Deaf, 1900, Department of Commerce and Labor, Bureau of the United States Census," present the following statistics and comments:

> Excluding congenital statistics and injuries, accidents and operations, there are 2,556 who lost sight after birth, but under 1 year of age, and in 644, or 25.2 per cent. of these cases, the cause of blindness was probably ophthalmia neonatorum, or "babies' sore eyes," since other diseases of the eye causing blindness under 1 year of age are extremely rare. The importance of these figures lies in the fact that

* Read at a joint meeting of the Chicago Medical and Chicago Ophthalmological societies in a "Symposium on Preventable Blindness," May, 1914.

this disease, which is very malignant and which attacks the infant at birth or immediately after and almost always results in total destruction of the sight—usually of both eyes—or in very seriously impaired vision, is now considered preventable, and if proper measures had been instituted at the time of birth, few or none of these cases would have occurred. It is not pertinent in this connection to discuss the means of prevention, which are well known; but it can at least be pointed out, with emphasis, that the so-called "sore eyes" of babies is a highly dangerous affection, and that its treatment should be prompt and energetic and carried out by a thoroughly competent person.

The New York Association for the Blind in a pamphlet[1] on this subject says:

> The official census of the blind for the state of New York, taken in 1906, gives a total of 6,200 blind persons in the state. Of these the cases of preventable blindness numbered 1,984, or 32 per cent., of the whole. And of these preventable cases there are 620 classified as blindness caused by ophthalmia neonatorum, or 10 per cent. of the whole number of blind persons in the state of New York. This means that to-day there are over 620 blind persons in this state who would never have been blind had a harmless preparation (Credé's method) been put into their eyes when they were born.

From the same instructive pamphlet Tables 7 and 8 are taken.

Table 7 shows the number of new pupils admitted into ten of the principal schools of this country during the year 1907, and the proportion of those admitted who had lost their sight from ophthalmia of the new-born.

TABLE 7.—NEW PUPILS IN 1907 BLIND FROM OPHTHALMIA

Schools for the Blind	New Admissions	Ophthalmia of New Born	Per Cent.
N. Y. State School for the Blind, Batavia, N. Y.	13	4	30.76
Penn. Institute for the Blind, Overbrook, Pa.	27	9	33.33
Perkins Institute and Mass. School for the Blind, Boston	43	13	30.23
Colorado School for the Blind, Colorado Springs	7	3	42.85
Western Penn. Institute for the Blind, Pittsburgh	28	8	28.57
Missouri School for the Blind, St. Louis.	19	6	31.57
Conn. State Board of Education for the Blind, Hartford	8	1	12.50
Ohio State School, Columbus	36	7	19.44
Maryland School for the Blind, Baltimore	13	4	30.76
Ontario Institute for the Blind, Brantford, Ont.	23	5	21.73

The average of new admissions in these ten schools for the blind shows that 28.14 per cent. were victims of ophthalmia of the new-born. More than one-quarter of the new pupils admitted during 1907 were therefore needlessly blind.

Table 8 shows the admissions for eight years, 1900-1907, to one school, the Pennsylvania Institute for the Blind, at Overbrook, Pa., and the percentage of pupils admitted each year who had lost their sight from ophthalmia neonatorum.

TABLE 8.—PUPILS BLIND FROM OPHTHALMIA ADMITTED TO PENNSYLVANIA SCHOOL FOR THE BLIND

Year		Per Cent.
1900	11 out of 25 =	44
1901	10 out of 28 =	35
1902	9 out of 39 =	23
1903	14 out of 50 =	28
1904	15 out of 58 =	25
1905	21 out of 42 =	50
1906	12 out of 38 =	31
1907	9 out of 34 =	26
1908	11 out of 29 =	37
1909	15 out of 34 =	44

Average for ten years 33.68 plus per cent. needlessly blind.

It is instructive also to note the statistics given in this pamphlet relative to the activity of midwives in obstetric practice:

> In Chicago, in 1904, we find 86 per cent. of all births, principally among Italians, reported by midwives. In Buffalo, N. Y., with a population of about 400,000, nearly one-half of the births, in one year, were attended by midwives. In New York City, in 1905, 43,834 births, or 42 per cent., of the whole number, were attended by midwives, employed largely by Italians, Austro-Hungarians, Polish Jews and other immigrants. For the year 1907, in New York City, there were 68,186 births reported by physicians, and 52,536 reported by midwives. In September, 1908, the registered midwives in the five boroughs of New York City numbered 1,382.

The author of these reports well concludes:

> In the face of these figures it is idle to talk of the elimination of the midwife. . . . Let us see to it that our midwives are trained, controlled and made fit for the responsible duties they undertake to perform.

The economic side of the question is likewise a matter of considerable moment. It is estimated that it costs the state $3,000 to educate a blind child. The proper equipment and maintenance of blind schools, etc., likewise require a considerable expenditure. To these sums may be added the loss to the individual in earning capacity, the curtailing of "avenues of-opportunity," etc., which his affliction necessarily imposes.

The disease itself—its etiology, pathology, clinical course and treatment—while not properly within the scope of the present consideration, may be given a brief reference.

Ophthalmia neonatorum is an acute purulent conjunctivitis occurring in the new-born. The cause of the infection is the gonococcus of Neisser. Bacteriologic examination has demonstrated that cases occurring before the end of the third day are almost always due to the neisserian infection. Later infections are usually produced by the Koch-Weeks bacillus, the pneumococcus, the Klebs-Loeffler bacillus, etc.

It is generally admitted that infection, as a rule, takes place from the vaginal secretion of the mother entering the conjunctival sacs during the period of the passage of the child's head along the genital tract. Ante-partum infections are recognized as of rare occurrence; post-partum infections from soiled linen, etc., also occur.

The appearance of an eye suffering from ophthalmia neonatorum varies according to the stage of the infection. At the outset, the conjunctiva is reddened; by the third day the lids are glued together with mucopus, the lids become swollen, and as the process develops, the discharge changes to a copious, creamy pus; the ocular conjunctiva becomes greatly swollen, and difficulty is experienced in separating the lids; the cornea may become hazy and ulcerated; gradually the process subsides, the swelling and discharge diminish, and the disease passes into a subacute stage.

The distinguishing characteristics of the disease are the swollen condition of lids and conjunctiva, and the purulent discharge. Corneal involvement, with its sequelae, is the danger that threatens the integrity of the visual function. It may be accepted as an axiom that a discharging eye is always a dangerous eye; and in the case of an infant, such a discharge occurring within the early days following its birth demands prompt identification and energetic treatment.

As far as the treatment of the disease itself is concerned, the recognized procedures all have this in common, namely, to negative the action of the invading organism, to keep the eye freed from the purulent secretion, to anticipate corneal involvement, to assist the reparative process and prevent the spread of the infection.

---

[1] New York Association for the Blind, Special Committee on Prevention of Blindness.

The greatest field of opportunity, however, lies in the prevention. To accomplish the highest degree of success in this direction two important factors must be carried out: first, the utilization of prophylactic measures; second, early recognition and prompt treatment of the disease.

As to prophylactic measures, obstetricians advise—as a routine procedure—the rendering of the genitals and genital tract aseptic by suitable measures; and such procedures, it is recognized, may prove of especial importance in preventing an infection.

The value of the Credé method as a prophylactic measure is generally admitted. At birth the child's eyes are gently cleansed and one drop of 2 per cent. solution of silver nitrate instilled into each eye. Credé, at the Leipsic Lying-in Asylum, had averaged 10.8 per cent. of cases of ophthalmia; after the introduction of this prophylactic method he found that the infections were reduced to from 0.1 to 0.2 per cent.

If this method of prophylaxis were in universal use, it is certain that the proportion of ophthalmia neonatorum cases would be greatly reduced; and if, in conjunction with the method, practical measures might be devised to insure the early recognition and early treatment of the disease, it is not unreasonable to assert that such infections might be almost entirely eradicated.

A survey of the foregoing facts, which embody the observations and the views of numerous earnest workers in this humanitarian field, causes one to pause and reflect on the colossal problem of prevention which is presented. The committee of the Chicago Opthalmological Society is determined to do what little it may in ameliorating the conditions and, if possible, inaugurate in the state of Illinois a practical campaign of prevention.

A cursory study of the situation discloses many perplexing problems which only patience, perseverance, discretion and cooperation may overcome. The plan proposed and carried out by the New York Association for the Blind appeals to our committee as one most likely to accomplish the largest measure of success, and at present we are engaged in attacking the problem along the lines suggested.

This plan is described by the New York Association for the Blind as follows:

> The methods of work for the suppression of infant ophthalmia may be divided into the following groups:
>
> 1. Educational.
> 2. Legislative.
> 3. Cooperative.
>
> *Educational.*—Through the preparation, publication and dissemination of printed matter, emanating from the committee or approved by it; through public lectures, addresses and exhibits; and by means of the press, on whose generous assistance the committee greatly relies.
>
> The object sought is to spread among the general public the knowledge that infant ophthalmia is a dangerous, infectious disease, fatal to sight unless checked at the time of the birth of the child, easily preventable then if simple precautions are taken; to inform parents, more especially, of the dangers which threaten the sight of their children at birth, and the preventive measures which should be taken; and to advocate the universal adoption of such measures.
>
> *Legislation.*—To promote such legislation as may be needed to accomplish the object in view—the prevention of the unnecessary blindness of infants.
>
> *Cooperation.*—In furtherance of the same object, the committee seeks and invites cooperation with medical societies, health officers, ophthalmic, maternity and other hospitals in which children are born, dispensaries, city missions, settlements; with schools, institutions and associations for the blind, and with all societies engaged in work for children and for social betterment; with district visiting nurses, and with all persons who are already engaged in this work or who desire to help in it.

The foregoing "plan of campaign" appears logical and practical, and in conducting the work along these lines our committee is sanguine that a measure of success will be attained which shall serve to place our own state in a creditable position on the question of the prevention of blindness due to ophthalmia neonatorum. Even a small measure of success will be a distinct accomplishment, and will contribute a not inconsiderable part toward sparing many little ones the sad ravages which this baneful disease inflicts.

104 South Michigan Avenue.

MANAGEMENT OF DELICATE AND PREMATURE INFANTS IN THE HOME*

H. M. McCLANAHAN, M.D.
OMAHA

The premature or delicate infant has an equal right to life with the robust. Indeed, its frail condition should insure it every possible care, since because of its feebleness its life's prospect is not nearly so good. While I have no available data, such at least is my personal experience. The fact that I have seen several striking examples of the possibilities of saving the lives of some of these cases and believe that not sufficient care in their management is practiced, is my excuse for presenting this brief paper.

The two general requirements in the care of premature infants are the maintenance of body heat, and proper nourishment.

I. THE MAINTENANCE OF BODY HEAT

In order to sustain life, body heat must be maintained and also the rapid dissipation of heat prevented. Heat is given off from the body by the excretions and feces and urine, by the lungs in the form of vapor, and from the skin. Vierordt states that 73 per cent. of body heat is eliminated by radiation and conduction from the skin. This heat loss can be greatly limited. My experience in a number of cases with the modern incubator has not been satisfactory. The infants live a few days and then die even when they are not losing weight. For the last several years I have adopted the following method. It is not at all original and the method is described in some of our modern text-books.

I direct that an ordinary clothes-basket 24 inches long be procured. This can be purchased in any village. The bottom is padded so that the basket has a depth of 8 inches. It is then lined with white oilcloth and over this a layer of cotton batting held in place by being stitched through the sides of the basket. This in turn is covered with white flannel. The flannel covering for the basket is fastened over the top by means of safety-pins so that the upper portion can either be turned back or fall about the neck of the infant, leaving the body surrounded by an air-space.

---

* Read before the Section on Diseases of Children at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

Heat is maintained by means of hot-water bottles. I always direct that these be covered by flannel. The 12-ounce citrate of magnesia bottle is convenient, as it has a rubber cork and a wire fastener that insures against leaking. Five of these bottles are sufficient to maintain proper temperature. A thermometer is kept in the basket and the heat maintained at from 90 to 95 degrees. During the night when the room temperature is lower it may be necessary to cover the basket with a rubber sheet in order to maintain the temperature. It will be noted that while the body is in a warm atmosphere the face is exposed so that the infant breathes the atmosphere of the room. As the room can be well ventilated it breathes, I think, a better air than when confined in an incubator.

The body of the infant is anointed with olive-oil, wrapped in a layer of cotton batting—loosely applied—and this in turn in a soft flannel blanket. The infant can be fed in the basket without being removed. Indeed, it need be taken out only when it is necessary to oil the body. Absorbent cotton pads can be used for napkins.

As soon as the infant begins to gain in weight the temperature of the basket can be lowered and in my experience in from two to three weeks the hot-water bottles can be dispensed with.

II. NOURISHMENT

This is vitally important because of the caloric needs of the infant. Breast-milk of course is the best food, but as emphasized by Drs. Holt and Morse, breast-milk should be diluted. Many of these infants are not strong enough to draw milk from the breast and there is no doubt in my mind that physicians and attendants are frequently deceived in believing that because the infant takes the breast it is getting nourishment. Only recently I was able to demonstrate to the attendant by weighing the infant before and after a breast-feeding that there was no appreciable gain in weight. In these cases the milk should be pumped from the breast regularly, diluted with an equal quantity of water, and fed to the infant. If it does not retain this dilution then the milk should be further diluted. Whatever dilution the infant takes, the food should be rapidly increased in strength. There are cases in which the infants are not strong enough to nurse from the bottle and in these cases some other method must be adopted. In these cases I have found the Breck feeder a life-saving appliance. At the Child-Saving Institute this method of feeding is frequently employed with normal infants who refuse to take the bottle. It seems to me superior to the medicine-dropper and certainly requires less skill than gavage.

For the first two or three days at least, food should be given every hour; after this the feeding interval should be lengthened. When it is not possible to procure breast-milk, then the feeding becomes very important. In two recent successful cases I began with the following:

Whey	5 parts
Water	5 parts
Milk-sugar	1 part
Lime water	1 part

In one of the two cases the infant vomited this food. I directed that the whey be made from skimmed milk, when it retained its food. As soon as it retains this formula nicely, the strength should be increased by the addition of either milk or cream.

CONCLUSIONS

1. The premature or delicate infant may develop into a strong individual. I have in mind three of these cases. One patient was normal in weight at 5 months. The other I had the privilege of examining at the age of 3 years. It was in every way a normal child. The third is now a young man in his twentieth year. He is normal physically and above normal in his intellectual attainments.

2. Among dangers to be guarded against are the regurgitation of food in the throat and the suction into the larynx. I have seen one fatal case from this cause. Temperature should be taken in order to guard against fever. In a recent case that I saw with the physician, the temperature reached to 105, due as I believe to the excessive external heat. In every case a thermometer should be kept constantly in the basket. The most frequent mistake, however, is letting the infant take the breast and assuming that it is actually getting food, or if it vomits assuming that the breast-milk does not agree with it.

3. Finally, the hopeful symptoms are a gain in weight and normal yellow stools.

Brandeis Building.

ABSTRACT OF DISCUSSION

DR. HENRY DWIGHT CHAPIN, New York: I wish to emphasize what Dr. McClanahan has said concerning incubators. I treated about 150 babies in different incubators and almost all of them died. While we gain in one factor, that is, heat, we lose in a vital factor, and that is fresh air. Most of them do not deliver sufficient fresh air to the infant, and these premature infants are unusually susceptible to lack of air. I think incubators should be abandoned entirely. I have used such appliances as Dr. McClanahan suggests. In the hospital I have two modern incubators but I do not use them. These premature infants have great difficulty in swallowing. Some of them are so difficult to feed I have been obliged to resort to gavage. I have saved one or two that I am sure would have otherwise been lost, by feeding in this way. One or two have died suddenly. Necropsy showed food had gone into the larynx. The nurse must be warned about slow feeding with any kind of a feeder.

DR. JOHN ZAHORSKY, St. Louis: Most of us who have had experience with expensive apparatus for warming babies have discontinued its use. One method is valuable in the ordinary home; that is, to use an ordinary soap-box, and an ordinary steam or hot-water radiator, and put the box with one side to the radiator so that the heat from it will pass into the box. The heat can be regulated by putting the box nearer or farther away from the radiator. This method can be used with the ordinary stove, with which, of course, someone will have to see that the fire is uniform. The distance will regulate the amount of heat the baby gets. Especially are mistakes made in the amount of heat to which the baby is subjected. Some nurses seem to think the warmer the baby is kept the better. The most common injury to the baby is from too much heat, which will produce injury that it may take a few days to overcome. It often produces cyanosis and death. A good rule is not to keep the temperature over 90. From 86 to 88 is usually sufficient. Watch the baby's rectal temperature, and if it goes lower than 96 degrees do not heat the incubator but warm the baby with a hot bath. Heating by hot air is a slow process. Most premature babies that are not sickly in any way die of exhaustion because they are not sufficiently fed. After the third or fourth day they get attacks of cyanosis, which means exhaustion of the respiratory center. In some way the baby must get enough food or it will die. The premature baby should have one-fifth of the body-weight in mother's milk daily. Commence on one-twentieth of the body-weight the first day—do not wait three days as we do with the normal baby, but commence to feed at once. It has no reserve store to sustain life. Every day the amount should be increased until it reaches one-fifth of the body-weight. It is best given with a dropper, a spoon, or, as Dr. Chapin has emphasized, with a catheter. One may get it down in six feedings, or it may take ten, twelve or even twenty-four, but the baby must receive one-twentieth of its body-weight during its first twenty-four hours.

L. R. DeBuys, New Orleans: The principal problem we have is to maintain the body temperature, and in doing this we have to be careful not to get it too high. A plan I have used is to make a gown of two layers of Canton flannel with one layer of cotton batting between. The baby is put in this and the warmth put externally—either hot bottles or hot-water bags. Covering all is a blanket. Another point that has not been mentioned is the placing of a thermometer inside the top covering and external to the baby's gown, to which it is pinned. You can tell then whether you are giving the baby enough or too much heat.

Dr. S. M. Hamill, Philadelphia: I, also, protest against the use of the older type of incubator, and emphasize one point in Dr. McClanahan's paper that seems to me important in the case of the premature infant, namely, supplying a sufficient amount of fresh air. I have not used an incubator for some years. I have been following much the same course that Dr. McClanahan has outlined. I had an experience a year and a half ago, which demonstrated that at least one premature infant was able to breathe an air of low temperature without detriment. I had the infant forced on me in the children's ward of the Polyclinic Hospital. None of the small rooms in the hospital were then available. Being an advocate of fresh air, I keep the windows open constantly, winter and summer. Having had this child brought into that ward it became necessary either to rob the children in the ward of their usual amount of fresh air, or to keep the windows open and endeavor to maintain the body-heat of the premature infant while at the same time letting it breathe the cold, fresh air of the ward. On the principle of doing the greatest good to the greatest number, I chose the latter course, and put the baby in a specially prepared clothes-basket close to a radiator. I succeeded in maintaining the heat about the body of the baby at from 90 to 95 F., whereas the temperature of the ward often fell as low as 50 or 55 F. at night. That baby did better than any premature baby I have ever seen. I have had experience in keeping these babies in room temperature of from 65 to 70 degrees for a short time, but never before at such a temperature as that above indicated. I am not advocating this as a proper procedure, but it illustrates the fact that these babies can breathe an air at low temperature without harm.

Dr. F. B. Talbot, Boston: Concerning the conservation of energy in the new-born, the new-born baby maintains his own body-heat after birth by using up the glycogen which has been deposited in the liver. In a certain number of instances when all the glycogen is used up, the body-fat is converted into sugar, and is used in this form. If the mother's milk comes in on the third day, and often later, they may not use their own body-fat at all. Under those circumstances they do not lose weight. If it does not come until five or six days they lose a good deal of body-fat and weight. The obvious conclusion to draw from this is that if the baby has not much fat, is not well developed, is a weak baby, it must be fed early to give it energy to keep its life, and to maintain its body-heat. This discussion goes with accurate scientific measurements of heat and determination of the respiratory quotient.

Dr. F. N. Rogers, Manchester, N. H.: One point I would bring out that Dr. McClanahan mentioned in his clothes-basket arrangement is that the weight a child would lift by respiration is simply the displacement of air. When cotton batting and pads are put about the child, there is apt to be more or less weight to be displaced, which takes energy.

Dr. Henry F. Helmholz, Chicago: In those cases with syncopial attacks during the first or second day, I have used in two cases 6 per cent. dextrose solution with excellent results. The child in one instance was practically moribund, but responded quickly to an ounce of 6 per cent. dextrose solution. That was kept up at five-hour intervals. There was no breast-milk available and the child from that time on did very well. The following day we were able to obtain some breast-milk, and the child recovered. The dextrose was administered hypodermatically.

Dr. H. M. McClanahan, Omaha: Some years ago I bought what I thought was a model incubator, and all our premature babies died about the fifth or sixth day, until I became discouraged. In all the cases I cited in my paper I was called to the home. Gavage is not as convenient there as in the hospital. The infant should not go too long without food. I believe a thermometer should be constantly present in the basket, and the temperature of the basket should not go above 90 or 95. Secondly, I emphasize, also, the danger of letting a baby's temperature go to 104, 105 or 106. In the last child I lost, one I saw an hour before it died, the temperature was 106, I believe due to the carelessness of the nurse in letting the temperature of the basket get too high. The temperature should be taken as a routine measure every twenty-four hours at least.

INTRACRANIAL HEMORRHAGE IN THE INFANT

WITH HISTORY AND NECROPSY REPORT OF A CASE

J. W. Shuman, M.D., Sioux City, Iowa

Recently I was called to conduct a necropsy in the case of an infant succumbing to some obscure lesion, and through the kindness of the attending physicians, Drs. J. W. Flageolle and G. S. Browning, the following clinical history was obtained:

History.—Dr. Flageolle was called Aug. 18, 1914, to see baby G. W., aged 6 weeks. The child had not been well since the sixteenth, but not ill enough to need medical attention. The history was negative as to traumatism or syphilis. He found the baby irritable when disturbed. There was considerable tenderness over the lower abdomen but no distention; the mother stated that the baby cried in his sleep and also when she attempted to pick him up. There had been no spasms, the Cheyne-Stokes respiration was present, the temperature was 98.6, pulse 90, and as no bowel movement had been secured since August 16, attempts were made per enemata to empty the bowel, but without satisfactory result. The following day at 9 a. m., Drs. Browning and Flageolle examined the child noting the following: pupils unequal (left dilated, right, "pin-point"); Cheyne-Stokes respiration, clonic spasms, some cervical rigidity and Kernig's sign positive. The clinical diagnosis of cerebrospinal meningitis was tentatively entertained. Death occurred without any change in symptoms at 1 p. m., of the same day.

Necropsy.—Necropsy was held at 4:30 p. m., the same day, showed a well-nourished child, with slight bulging of the fontanelles and rigor mortis pronounced; an elongated prepuce with pin-point opening was noted. There were bluish-red discolorations on the back and left leg (post-agonal).

The thoracic and abdominal findings were negative except as to the colon, the mucous membrane of which was dotted with numerous small ecchymotic areas, extending from the ileocolic valve to the anus, with a slight membrane present, which was easily washed away.

No ecchymosis or other evidence of traumatism on the scalp or exterior surface of the skull. On incising the dura mater the brain substance exuded, denoting increased intracranial pressure. The consistency of the brain tissue was extremely soft and pulpy rendering it impossible of manipulation; the cranial bones were normal. On removing the cerebrum subdurally and left posteriorly a well organized, dark blood-clot (1½ ounces) was found compressing, but no attached to the brain. The brain substance was so soft that definite localizing with it was impossible; no communicating vessel could be observed. A small amount of blood-tinged cerebrospinal fluid was present; smears made from it and examined proved negative for micro-organisms; the cerebellum and medulla evidenced no abnormalities and were normal in consistency.

Pathologic Diagnosis.—Cause of death (1) cerebral pressure, due to (2) subdural hemorrhage (left posterior); (3) cause (?); (4) mucocolitis (mild).

This instance is reported to call attention to the fact that a necropsy is invaluable in checking up the clinical diagnosis and in making a correct finding of the "cause of death." The greatest interest, however, centers in the question as to the cause of the hemorrhage. As noted, there was no sign of traumatism to the head nor was there any fever to indicate acute meningeal infection or brain abscess.

Had there been severe trauma during delivery sufficient to cause hemorrhage, symptoms would have developed before six weeks, but up to that time the child had been apparently normal. With no previous derangement, as convulsions or severe coughing to increase the intracerebral blood pressure, and no traumatism to the head, the cause of the hemorrhage remains an unsolved problem.

Choyce (A System of Surgery, iii) quoting Karl Henschen (Verhandl. d. Deutsch. Gesellsch. f. Chir., 1912) states that it is only comparatively recently that the head injuries that the child is liable to during birth have received due attention from diagnosticians and surgeons and that the frequency of intracranial hemorrhage in the newborn has been observed in several long series of necropsies and results have differed considerably. Some observers have found hemorrhage in 2 per cent. of all post-mortem examinations of young infants; others in as many as 12 to 13 per cent. It is certainly far from an uncommon injury and it must be remembered that probably a large number of infants recover from it with or without persistent symptoms. The frequency of the so-called congenital and infantile hemiplegias and diplegias confirms this view.

It is further claimed that the commonest lesion is the subdural hemorrhage; laceration of the veins entering the longitudinal sinus and laceration of the tentorium are the chief sources of the bleeding. Even abnormally quick labor and cesarean sections have been followed by it. The hemorrhage usually occurs at or in a few hours following birth, but may not manifest itself for days or even weeks, clinically, and it is probable that convulsions occurring within a few weeks of birth are due to traumatic lesions of the brain. The newborn's brain is very tolerant of compression and consequently the symptoms are apt to be slight or obscure. Definite localizing symptoms are frequently, perhaps usually absent. The tendency to hemorrhage not uncommonly present, especially in syphilitic infants, is probably an important factor in many cases.

A Suggestion Concerning Passive Congestion in Rheumatism.—I desire briefly to call attention to a little procedure commonly used by surgeons with benefit in treating infections and which may be useful in the treatment of acute articular rheumatism. I refer to passive congestion produced by constriction of an extremity or otherwise. Acute articular rheumatism is a systemic infection with particular affinity for joint structures, and this procedure, which aids Nature by flooding the involved portion with Nature's own anti-bodies, is sound in principle. Venous congestion does more than this, however, when salicylates are being administered. The ingested salicylates exist in the alkaline blood and tissues only as salicylates, and these have no germicidal action. However, in the presence of greatly increased carbon dioxid tension, some salicylate is converted into salicylic acid, and this is a powerful germicide. It is supposed that in the congestion of an inflamed joint this conversion takes place. Thus if the salicylates do have any direct effect on the organisms causing the disease, that effect is increased by retarding the venous circulation of a part involved.—J. S. Lancaster, M.D., Los Angeles.

Therapeutics

PREVENTION IS GREATER THAN CURE

VIII

DUST

We have already briefly referred to what is now understood as pure air, and the effect of stagnant and overmoist air on the individual. The injury caused by dust or impure air, however, has not been sufficiently emphasized.

The excellent discussion of this subject two years ago by Prof. Charles Baskerville of the College of the City of New York[1] has been used as a basis for this article.

For practical purposes the impurities of the air may be divided into two classes, dust, and fumes or gases. In the cities the dust contains pulverized excreta of human beings and animals, the material which is constantly being worn from the buildings and pavements, the waste from houses, stores and factories, micro-organisms, leaves, remains of fruit, and other parts of plants and trees. It is interesting to know that the air of subways contains many minute angular particles of iron.

In the country the dust consists to a larger extent of particles worn from the road. The substances of which the road is composed are more or less pulverized by the traffic. This dust is especially increased by heavy carts and automobiles. The country roads are disintegrated in part by the frosts of winter, in part by the wind, by the action of the falling rain, and by the transporting power of water. Oiled roads, as soon as they dry, give rise to particles of crude, irritant tar-oil which are wafted with the dust.

These components of the dust are all more or less irritating, not only to the mucous membrane of the respiratory tract, but also to the eyes. When the amount of dust is small the irritation may be slight, but when the amount of dust is large and when there is a considerable amount of tar-oil present, the irritation may be very troublesome.

The prevention of this dust is accomplished by care in the building and in the maintenance of the roads. The best structure for a roadbed and top dressing must be decided by the region, by the variations in climate, by the geography of the locality, and by the character of the traffic. There is doubtless no one best roadbed.

There is no question of the necessity for a city to water its streets. There, also, seems to be no question of the advantage of oiling turnpikes and country roads, if they are built of material that allows of oiling. Whether or not a city should oil its streets is a subject for discussion.

Baskerville suggests as a suitable disinfectant and agent for the diminution of dust a very dilute chlorinated lime solution. The chemical is cheap, and any outlay entailed would be more than covered by the decrease in dust-borne diseases. He also calls attention to Dr. Nesbit's work in ridding Wilmington, N. C., of flies by sprinkling the streets five times with an attenuated mixture of water with light pine-oil. An incidental effect of the suppression of the flies was the stamping out of a typhoid fever epidemic.

---

[1] Baskerville, Charles: New York Med. Jour., Nov. 23, 1912, p. 1061 and Nov. 30, 1912, p. 1119.

The other part of the impure air problem has to do with noxious fumes and gases, and is especially important in cities. There may be mentioned first the danger from illuminating gas. The chief poisonous constituents of this are "ammonia, hydrocyanic acid, hydrogen sulphid, carbon disulphid, other gaseous sulphur compounds, and carbon monoxid." The danger from the inhalation of concentrated illuminating gas, such as is often taken with suicidal intent, are too well known to require repetition, but the hygienic importance of good ventilation and the constant renewal of outside fresh air to a room where illuminating gas is constantly, or for a long time, burning is not sufficiently understood. Also, the depressing influence and the actual blood disturbances, even anemia, caused by the constant inhalation of the gas from an illuminating-gas leak in a house or building is not sufficiently noted, and is not investigated by boards of health as it should be. Leaks of illuminating gas, which occur so constantly and frequently in tenement houses, stores and factories, have not been sufficiently considered as a menace to health.

The atmosphere outdoors in manufacturing towns is contaminated extensively with the smoke produced by the combustion of large quantities of coal. The combustion gases from this source are of a highly poisonous nature. They may be diminished to a considerable extent by proper management of the fires by skilled firemen. An important constituent of this smoke is the soot, which is due to incomplete combustion, and which may be "formed partly by the mechanical removal of dust by the chimney draft, and partly by the decomposition of the fuel, such as takes place in the process of destructive distillation. It consists mainly of carbon, tar and ash or mineral matter together with small amounts of sulphur and nitrogen compounds, and often possesses an acid character." The sticky properties of soot are due to the tar which it contains.

Sulphur dioxid is one of the most important impurities of city air, especially in manufacturing towns, and this is derived to a large extent from the combustion of coal and of coal gas. Its presence in the air has a serious effect on susceptible persons, and particularly damages the respiratory organs. It tends to cause anemia and bronchitis. Various efforts are made to discourage the dissemination of smoke in communities. It has been suggested that more might be accomplished if the matter were placed by municipalities and boards of health "in the hands of men qualified to assist manufacturers to suppress the nuisance without causing them difficulty." Methods have been invented whereby much of this waste combustible material may be collected with profit to the manufacturer and with health and happiness to the surrounding community. The smoke nuisance should be most seriously considered by all cities.

The dust which is present in the air of many shops and factories, and which is produced incidentally to the various processes employed in the mechanical arts, is a factor of considerable importance in connection with the health of the workmen.

These dusts may be divided into three classes: (1) insoluble inorganic dusts; (2) soluble inorganic dusts, and (3) organic dusts.

The first class, the insoluble inorganic dusts, includes metals such as antimony, arsenic, type metal, brass, bronze, copper, aluminum, iron, steel, lead, manganese, silver, tin and zinc, in a state of fine division; also various ore dusts such as that from iron ore, silica, sand, emery, flint, glass powder, carbon, graphite, diamond, coal, soot, brick dust, marble, granite, cement, terra cotta, lime, gypsum and plaster.

The second class, the soluble inorganic dusts, includes substances which may be swallowed and absorbed, such as metallic particles like lead, brass, zinc, arsenic, mercury and silver, and soluble inorganic salts.

The third class, or organic dusts, includes "sawdust, fur, skins, feathers, broom and straw, grains and flours, jute, flax, hemp, cotton, wool, carpet dust, street sweepings, tobacco and tobacco-box dust, hides and leather, felts, rags, paper, horsehair, etc."

These various dusts affect chiefly the respiratory organs, but to a less extent the eyes and the skin. In the lungs they produce a condition of fibrosis of the lung to which Zenker gave the name "pneumonokoniosis." Various forms of this disease have been described, depending on the nature of the irritant producing the fibrosis. Among them may be mentioned anthracosis, or coal-miners' disease, caused by the inhalation of the dust from anthracite coal; siderosis, caused by the inhalation of the dust from metals, especially from iron, and chalicosis, caused by the inhalation of mineral dusts, resulting in the so-called stone-cutters' phthisis and grinders' phthisis. The inhalation of iron dust diminishes the respiratory efficiency of the lungs by causing a lessening of their elastic property. It may also reduce the resistance of the lungs to invasion by harmful bacteria. That form of disease distinguished as siderosis exists with special frequency among metal polishers, knife grinders and others engaged in metal work.

Among the diseases caused by the organic dusts may be mentioned flax dressers' disease, a kind of pneumonia due to the inhalation of particles of flax and alkaloidal poisoning from African boxwood, seen in workmen engaged in shuttle making.

The prevention of these various forms of disease incidental to various forms of industry without unduly interfering with the profits of the business is often an exceedingly difficult problem. Among the suggestions which have been made, and which are employed with more or less advantage may be mentioned:

1. The removing of the dust from the room in which it is produced by forcible suction applied at the seat of its production. This is especially applicable in the trades of grinding and polishing.
2. When irritating dust affects the eyes, glasses for their protection should be worn by the workmen.
3. Those engaged in sorting rags in paper factories, workmen on threshing machines, millers, mixers in glass factories, stone cutters, sculptors and all others in factories where there is irritating dust should wear respirators over the mouth and nose to prevent the dust from entering the respiratory organs.
4. Those employed in the manufacturing of oxidizing agents or lead workers should change their clothes before leaving the factory.
5. The dust on the floors of printing, type-casting, metal-working and similar establishments should be laid by means of certain preparations adapted for this purpose. Probably the best are mineral oils which accomplish this result very satisfactorily.
6. General ventilation of the shop should be employed as far as practicable to dilute the unavoidable dust and remove it as far as possible.

7. The value of vacuum cleaning for factories should be emphasized as much as it is for office buildings, stores and private houses.

MINE SANITATION

While this subject is not of much general importance, it is of great importance to some of us, and should interest all. New methods of saving life and of avoiding accidents, and the condemnation of criminal carelessness should ever be subjects worthy of careful review, if not of individual study.

Mine problems, so well understood by some physicians, but so little by the majority, are splendidly outlined in an article by Dr. N. P. Brooks[2] which it would be well for all interested to read carefully. The main points for consideration are proper and scientific ventilation, proper lighting methods, methods to diminish dust, proper drainage, proper disposal of excreta of men and animals, and a greater care of the personal hygiene of the miners.

Briefly, the gases in coal mines are as follows:

CH_4, methane or marsh gas, is "colorless, odorless, tasteless, lighter than air, in a pure state burns with a blue flame, and is very explosive when mixed with certain proportions of air." When breathed in a pure state it affects the individual not unlike laughing gas, and does not cause harm when inhaled as long as the supply of oxygen is sufficient.

CO, white-damp or carbon monoxid, "is a colorless, odorless, tasteless gas, lighter than air, combustible, and explosive when mixed with a certain proportion of air." This gas is very poisonous, and if 1 per cent. of it is breathed for any length of time it produces dyspnea, headache, loss of sight, soon paralysis, beginning with the lower extremities, and finally unconsciousness. When unconsciousness is caused by carbon monoxid the patient may not be resuscitated at all, or if he is, his mentality may be seriously injured. A positive indication that this gas is accumulating in dangerous amount is shown by the death of white mice or other small animals, that should be kept in the mines where their condition can be readily observed by the miners.

CO_2, carbonic acid gas, carbon dioxid, "is a colorless, odorless, tasteless gas, heavier than air, and a non-supporter of combustion." The presence of this gas in abnormal amount is readily detected by the dimness of the oil lamps. The first symptoms of a poisonous amount of this gas are increased heart action, lassitude, and headache. If the amount of the gas is very considerable the individual may fall unconscious without even a cry. Men subjected to this poisoning may remain unconscious for some hours, provided they get a sufficient amount of oxygen, and still be resuscitated. "Suffocation ensues when there is 1 volume of this gas to 12 volumes of air."

H_2S, hydrogen sulphid, stink-damp, does not frequently occur in mines, but is very poisonous. Its obnoxious odor causes it to be quickly detected.

Lighting, ventilation and methods of diminishing dust are too technical to be discussed here. Carelessness in the drainage of mines, from the effect that bad drainage can have on the miners, should not be tolerated. Miners who must work all day with wet feet are certainly rendered liable to colds, joint affections and neuritis, if not to more serious illnesses. If they are barefooted, in certain regions, they are liable to acquire the hookworm disease. If they work in rubber boots, the sweating and general lack of elasticity caused by standing all day in rubber is a distinct disadvantage to the individual.

The care of the excreta in mines should certainly be under the control of the boards of health in the regions in which the mines are located, and sanitary measures, now well understood, should be established in every mine. The clothing and cleanliness of the miners and their drinking habits should all be subject to careful supervision, the two former for their individual welfare, and the latter not only for their own welfare but for that of others, as carelessness is an important factor in mine disasters.

As first aid to the injured in accidents and mine disasters must frequently be rendered by fellow miners or their foremen, instruction should be given to all in artificial respiration, in methods of stopping hemorrhage, in the first antisepsis and dressing of injuries, and in the action of the different poisonous gases. Foremen should pass an examination on such subjects.

(To be continued)

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

THE CEREBROSPINAL FLUID

The importance which attaches to an expansion of our knowledge of the functions of the cerebrospinal fluid in relation to many problems in surgery and medicine has been well summarized in a recent paper by Drs. Frazier and Peet[1] of the University of Pennsylvania. We are impelled to quote their own words because they emphasize so plainly the directions in which progress is demanded. The accumulation of cerebrospinal fluid in abnormal quantities, we are reminded by the Philadelphia investigators, is a factor which must be reckoned with in many intracranial diseases. It is accountable not only for many subjective and objective disturbances, but it is often the determining factor in the fatal cases. How essential it is in diagnosis, prognosis and treatment will be realized by the mere mention of such morbid conditions as hydrocephalus, brain tumors and meningitis. In the treatment of these, so far as it concerns the damaging effect of excessive secretion or inadequate absorption of cerebrospinal fluid, we are helpless and wofully unsuccessful. It is of the utmost importance, therefore, that investigation of the cerebrospinal fluid should be continued until the fundamental principles of secretion and absorption are thoroughly understood, in the hope of finding some effective means of controlling oversecretion or diminished absorption.

Not long ago we discussed some evidence that the cerebrospinal fluid is a typical secretion initiated in the "choroid gland" or choroid plexus of the various ventricles of the brain.[2] Frazier and Peet[1] have been able to elucidate the problem of the secretion and absorption of the cerebrospinal fluid by the production of artificial hydrocephalus. So long as the fluid is widely distributed throughout the subarachnoid and subdural spaces of the brain and cord, it is not easy to ascertain the location of changes in its make-up and movements. The fluid is produced almost entirely within the two lateral, the third and fourth ventricles. This was shown by effecting a closure of the lower end of the aqueduct of Sylvius whereby intracranial pressure is developed. A moderate hydrocephalus may arise without any signs of meningitis. Although the cerebrospinal fluid is without doubt secreted mostly, if not entirely, within these brain cavities, absorption from the ventricles is practically negative and does not take place until the fluid has escaped. The lateral ventricle, therefore, is merely a receptacle, like the bladder, for the storage of fluid. Frazier and Peet agree with Dandy and Blackfan[3] in believing that it is possible to differentiate different types of hydrocephalus from the point of view of etiology, for instance, those with from those without obstruction of the ventricles, by introducing a detectable substance like phenolsulphonephthalein into the ventricles and watching the rate of its reappearance in the excreta. In obstruction this will be extremely slow.

Dixon and Halliburton[4] venture the belief that some product of the brain's metabolism passes to the choroid plexus, and that this stimulates the secreting epithelium, which causes the plexus to become active. This is essentially the postulation of a "hormone" regulation of the production of cerebrospinal fluid. The normal rate of secretion was found by Frazier and Peet to vary widely under normal conditions. It has been suggested that the secretion of cerebrospinal fluid may be controlled by ligation of the common carotid arteries, and this operation has even been recommended in the treatment of hydrocephalus. It is, of course, very desirable to know the effect of disturbance of the cerebral circulation on the rate of secretion in order to place any indicated operative procedures on a sounder scientific basis. In Frazier and Peet's experience, in an observation on man, the rate of secretion was practically uninfluenced by so profound an interference as the ligation. We are inclined to urge, therefore, until contradictory evidence is forthcoming, that the operation of ligating the common carotid arteries should not be endorsed with the expectation of influencing favorably the hydrocephalus that is either of congenital origin or the accompaniment of brain tumors.

Inasmuch as the venous circulation appears to be concerned with the absorption rather than the production of the cerebrospinal fluid, it is not to be expected that disturbances of its mechanism would affect the secretory output of the choroid plexus. Impaired absorption might be expected under certain of these conditions, especially since it has been found that the lymphatics play at best an inconsequential part in the absorption of cerebrospinal fluid. Frazier and Peet remind us that pressure on the sinuses and obstruction to the venous circulation is no doubt a factor in the accumulation of cerebrospinal fluid so frequently associated with brain tumors, especially of the posterior fossa. As the major portion of the venous circulation of the brain, including the cerebral veins and dural sinuses, leaves the cranial cavity from a point in the posterior fossa, the jugular foramen, it is readily understood why posterior fossa tumors are so frequently and at a comparatively early stage associated with increased intracranial tension which comes from the accumulation of cerebrospinal fluid. In other words, obstruction to the venous outflow is immediately followed by a rise in venous pressure, by the accumulation of cerebrospinal fluid, and a resulting increase in intracranial tension.

[4] Dixon, W. E., and Halliburton, W. D.: The Cerebrospinal Fluid, I, The Secretion of the Fluid, Jour. Physiol., 1913, xlvii, 215.

The cerebrospinal pressure has been observed by Frazier and Peet to vary with the pressure of the venous sinuses and to be practically identical with it. Under normal conditions, there are certain oscillations which are due to the effect of inspiration and expiration on venous pressure, but they may be arrested by slight increase of intracranial tension. Closure of the carotid circulation causes an immediate, though only transitory, fall of cerebrospinal pressure; but obstruction of the venous circulation is followed by an increase in pressure more or less constant.

Dixon and Halliburton[5] have now added to their earlier investigations[4] a consideration of the effect which marked changes in cerebrospinal pressure produce on other functions. A relatively small increase in cerebrospinal pressure causes stimulation of the respiratory, vasomotor and cardio-inhibitory centers. The stimulating effect is least marked on the respiratory center. When the pressure is increased to a height considerably above the normal arterial pressure, respiration ceases in a few seconds, but the other two centers remain active and the arterial pressure rises enormously in spite of the slow heart; a little later the cardio-inhibitory center is paralyzed, and the continued activity of the vasomotor center still further raises the arterial pressure. This represents, as Cushing[6] has pointed out, a protective mechanism which continues to force the blood along the compressed blood-vessels. Ultimately, however, if the high cerebrospinal pressure is kept up, paralysis of the vasomotor center ensues, and the arterial pressure then falls.

The results of Dixon and Halliburton in relation to the early depression of the respiratory center as the result of cerebral compression accord with the views of Horsley and his colleagues. Cushing has not quite agreed with them on the primary importance of respiratory failure. He regarded the cessation of breathing as the result of fatigue or failure of the vasomotor center which allows the blood-pressure to fall below the intracranial pressure. Anemia of the respiratory center consequently ensues, and respiration, already embarrassed, immediately ceases. At this stage, unless relief is given, the blood-pressure sinks to a level which represents irrevocable paralysis of the respiratory center. The English surgeon, regarding the respiratory center as the most sensitive to mechanical pressure and shocks, recommends that in cases in which death is imminent, in cases of intracranial pressure, artificial respiration should be immediately performed and the skull opened freely.

HIGH SCHOOL ATHLETICS

The Journal has freely expressed the view in the past that the competitive athletics of our American colleges and universities often harbor unsuspected dangers in that they encourage overdoing on the part of the participants. No one would gainsay that systematic and even strenuous exercise may exert a most wholesome effect on the human organism. But the win-at-any-cost exertion, taxing vital organs to the very limit of their endurance, exceeding the factor of safety in physiologic functions, and sometimes carried to the breaking strain, represents a sort of unjustifiable self-sacrifice that may properly be made for one's country but is never called for to uphold the glory of one's college. The sooner it is realized that there are better tests of manliness than the ability to endure a 4-mile race in the college boat or to complete the football season in spite of acquired injuries, the more wholesome will American college life become.

Unfortunately, there is a widely manifested tendency for the pupil of the high school to ape the performances of his older brother in the college. This is shown in the introduction of Greek letter societies and social functions into the secondary schools, tending to counterbalance some of their wholesome features of social intercourse with the snobbery of exclusiveness and the deteriorating influence of late hours and tiring distractions. Even more baneful, however, is the growing custom of allowing the same sort of intense competitive sports in the high school that are the cause of complaint in respect to their dangers to the older college student.

We are glad to note a spirit of protest awakened in various parts of the United States against all the forces, social and athletic, which tend to deteriorate the American boy (or girl) at the adolescent age of the high school period. One health officer has recently made a public announcement that proper exercise in a well-equipped gymnasium, under the guidance of a trained instructor, is good for any one, but that competitive athletics, requiring most strenuous exertion.

---

[5] Dixon, W. E., and Halliburton, W. D.: The Cerebrospinal Fluid, III, The General Effect of Increasing the Cerebrospinal Pressure, Jour. Physiol., 1914, xlviii, 317.

[6] Cushing, H.: Bull. Johns Hopkins Hosp., 1901, xii, No. 126; Am. Jour. Med. Sc., 1902, cxxiv, No. 3; Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1902, ix.

long and tedious training and self-denial, is positively bad for any one before full development, and that all such overacts tend to impair the keenness of the mind and interfere with school work proper, as well as to injure the body. The competitive interscholastic games which require great physical exertion and mental tension should be done away with and a good gymnasium, under the direction of one trained in physical culture, should be provided and work according to the condition and need of each pupil assigned.[1] We agree, further, that mild and well-timed athletic exercise and occasional social functions will tend to relieve the monotony of school life and invigorate body and mind; but overindulgence is likely to be detrimental.

The dangers referred to are not insignificant; they are real. Prof. C. R. Bardeen of the University of Wisconsin has pointed out, in connection with the participation in athletics in his institution, that the increasing amount of cardiovascular disease noted in this country by life-insurance companies and others makes it important for the physician to make himself acquainted with the chief causes responsible for these conditions so that he can protect his patients. Overexertion in competitive sports, especially in schoolboys, is one factor. From 5 to 10 per cent. of freshmen entering the state university have cardiac hypertrophy with dilatation attributable to athletic sports. While in most cases there is good compensation, in many there are mitral murmurs and a myocardial irritability which not only keeps these students out of college sports, but to some extent hampers their scholastic work in college. Practically all college students taking part in the major sports have hypertrophied hearts. While in many cases compensation is good, in a large number there is a myocardiac irritability, sometimes accompanied by mitral murmurs, which indicate somewhat serious lesions. In the past two years there have in addition been four cases of acute cardiac dilatation among the relatively few members of teams in the major sports to one case among the far greater number of students not members of teams. In the latter case the dilatation occurred while the student was running in the gymnasium.[2]

Criticisms of this sort are never welcomed when they contravene established customs. Yet there is an obvious contradiction in directing the energies and funds of the state toward the prevention of disease and the establishment of habits of right living in the earliest years of our public schools, only to permit their undoing at a subsequent period. School doctors and school nurses in the primary departments have come to stay for some time, at least. Why not more healthful school customs in later years?

FOOT-AND-MOUTH DISEASE

In view of the recent outbreak of foot-and-mouth disease in the Mississippi Valley, the most extensive as yet in the United States, a brief consideration of the principal features of the disease may be of interest. It is an acute, highly infectious disease, which occurs chiefly in cattle, sheep, goats and swine, though other animals such as the horse and dog, as well as certain wild animals are attacked also, and it may affect human beings. In animals it is characterized especially by the eruption of vesicles in the mouth and on the feet, in some species more in the mouth, in others more on the feet. In cattle the incubation period averages from three to five days, whereupon a moderate fever with loss of appetite and other general symptoms sets in. In two or three days small blisters appear on the lining of the mouth, and now the fever usually subsides. At the same time one or more feet may show tenderness and swelling of the skin, soon vesicles form here also, and the animal goes lame. In the mouth the blisters may reach half an inch or more in diameter, but usually they are smaller; the contents, at first clear, become turbid, and as the covering bursts, small painful erosions are produced which either heal quite promptly or turn into ulcers that heal more slowly. Usually the milk is altered and reduced in quantity; blisters and ulcers may form on the udder. There is marked loss of weight, as the animals do not eat because of the pain. In this, the ordinary form, in which the death-rate is very small except among the young, the symptoms fade away in from ten to twenty days or so, except when complicating local secondary infections delay recovery, but there are also severe forms with extensive infection of the respiratory tract and gastro-intestinal inflammation, which frequently end in sudden death. In such severe cases ulcers are found in the stomach and intestines. In sheep and swine, lesions of the feet predominate. The disease is transmissible to the fetus in utero.

The cause of the disease is present in the contents of the vesicles, the discharges from the ulcers, the saliva, the milk, the urine and feces, but as a rule not after the tenth day. It is stated that animals having had the disease may carry the virus for months.[1] Any susceptible species may infect any other susceptible species. Infection occurs not only through direct contact, but also indirectly, as the virus retains its virulence for some little time, at least outside the body. Contamination of fodder, of stalls, of feeding and drinking troughs, of milk and milk products and of the hands and clothes of drovers serves to spread the disease, which often travels over wide stretches of country with remarkable rapidity, as shown by the present outbreak. As from 25 to 50 per cent. of the cattle exposed to infection may become sick, there results great loss from fall in the production of milk, from reduction of vitality and fecundity, and from deaths as well as on account of the measures adopted to stamp out the epizootic.

---

[1] Moore: The Etiology of Infectious Diseases in Animals, 1906.

The immunity produced by an attack seems to be feeble, as animals are said to suffer sometimes more than one attack within a short time. So far no practical method of protective inoculation has been developed.

Our knowledge of the cause of foot-and-mouth disease is limited to the fact that it concerns a filterable virus, as yet invisible and incultivable. It was in 1897 that Löffler and Frosch made their classical experiment, showing that the disease is caused by a living, proliferative virus that passes filters which do not permit bacteria to go through, an experiment that has served as a model for all the subsequent work on the many other forms of filterable virus recognized since then. Foot-and-mouth virus may remain active for months if kept cool and moist, but is destroyed rapidly by drying, by heat at 60 C. (140 F.) and above, by formaldehyd and by phenol (carbolic acid). The wide range of virulence of this virus among animal species has been indicated, and as stated, the disease may affect human beings, especially children, being transmitted by milk from diseased cows (experimentally verified) and by butter and cheese made from such milk as well as through wounds and in other ways. While the course usually is favorable, an epidemic described by Siegel had a mortality of 8 per cent. The manifestations are fever, digestive disturbances and vesicular eruption on the lips, the oropharyngeal lining ("aphthous fever") and sometimes on the skin. Where there is danger of contamination of the milk with the foot-and-mouth virus, thorough pasteurization of all milk and milk products is doubly indicated.[2]

THE ACTION OF IODIDS ON THE BLOOD-VESSELS AND HEART

Recently we commented[3] on the use of sodium as compared with potassium salts, and noted that in most cases potassium salts are given not for their potassium content but for the therapeutic effects produced by the negative or acid radical, as for instance in the case of acetates, tartrates, carbonates, bicarbonates, iodids, etc. We stated also that probably the corresponding sodium salts might prove equally and sometimes even more serviceable since the sodium ion has a less depressing action on the heart and central nervous system than has the potassium ion.

In the case of such salts as quinin arsenate[4] and ferric arsenate,[5] the reports of the Council on Pharmacy and Chemistry have emphasized that both the acid radical and the basic group are therapeutically active. Not enough of one of the constituents of these can be given without perhaps a dangerous overdose of the other constituent. In general, however, we are inclined to forget that in almost every salt the effects of both the kation or positive radical and the anion or acid radical must be considered. A new investigation of D. I. Macht[6] has an important bearing on this subject.

For some years the iodids, especially potassium iodid, have been credited with having a vasodilator or blood-pressure lowering action and have found extensive application in the treatment of arteriosclerosis. Aside from cases with a luetic basis, however, no satisfactory explanation of the supposed usefulness of the iodids in arteriosclerosis has been offered; in fact, many have doubted the value of the iodids in this condition.[7] The only experimental basis for the belief that iodids lower blood-pressure seems to have been chiefly animal experiments in which potassium iodid had been injected intravenously and in which the relative parts taken by the potassium and iodid ions were not differentiated. That the potassium ion when present in the blood even in weak concentration (0.08 per cent., for example) leads to an almost instant stoppage of the heart has been known for some time and has led to unwarranted fears of possible dangers from the oral administration of potassium salts; as a matter of fact, potassium leaves the blood so rapidly, passing to the tissues or being excreted by the kidneys that, provided the latter are efficient, there is little or no danger from the administration, by the mouth, of even very large doses of the potassium salts.[8]

Macht now reports careful experiments on the heart and blood-vessels in which the relative parts taken by the iodid radical and the other (basic) constituent of the salt were carefully differentiated. In some experiments the potassium chlorid of the nutrient fluid was replaced by potassium iodid or, if a greater concentration of iodid was desired, part of the sodium chlorid was replaced by an equivalent amount of sodium iodid. By such experiments the relative amounts of potassium, sodium, etc., remained unchanged and if the modified fluid had an action on the organs different from that of the original fluid, it was due to the presence of this iodid ion. Such experiments showed that the iodid ion instead of having a depressing action on the heart and vessels, as has been assumed, has a marked stimulating action. This stimulating action, however, is somewhat inhibited by a combination of the iodin with the proteins of the blood. The sodium ion was found to have a slightly stimulating action, whereas the depressing action of the potassium ion was confirmed.

[7] See for example the summary of the opinions of many prominent German clinicians as given by J. Schwalbe in the Deutsche medizinische Wochenschrift, 1914, Nos. 14 and 15.

[8] Parenthetically it may be remarked that even the oral administration of large doses of potassium salts to patients suffering from severe nephritis must be regarded as distinctly dangerous and their use in intravenous or intraspinal injections in the doses in which sodium bromid, for example, has been used might prove fatal.

The action of the iodid ion on the heart and circulation, therefore, is that of stimulation. If an iodid has an action other than this it is due to the effect of the kation (potassium, etc.) with which the iodin is combined and should be attributed to it. The same effect may be obtained when this kation is combined with anions other than iodin. If conditions are such (intravenous injections, for example) that potassium i' causes a fall of blood-pressure, this result is due solely to the potassium ion and could be equally well obtained with other potassium salts (potassium chlorid, for example).

Such analyses of the action of common drugs will do much to clarify and simplify our materia medica. While bromid is used in the form of its potassium, sodium, ammonium and even strontium, lithium, rubidium and cesium salt, investigation will no doubt show that one of these deserves general preference when bromid action is desired. Such experiments will also emphasize the unscientific character of many hodge-podge official and proprietary mixtures in which an assortment of metallic salts of a therapeutically active acid radical are combined and from which physicians are inclined to believe that they may obtain effects far beyond those obtainable from any single salt.

SIMPLE NITROGENOUS COMPOUNDS IN NUTRITION

Among the seemingly radical suggestions that have lately found expression in discussions on nutrition is that of the possible utilization of such simple compounds of nitrogen as urea and ammonium salts in the animal organism. Even the nitrates have been drawn into consideration in this respect. The entire
subject, while by no means entirely new as a topic
for experiment and speculation in physiology, has
more ... while provoked a lively controversy in which
um.[2] 1 in Halle, Grafe in Heidelberg, and
Criticisms n New Haven — to mention only a few
they contrav re prominent participants — have taken an

2. Bardeen, C. simple protein derivatives as the amino-
The Journal A. M.

acids in the functions of nutrition would have seemed at that time like contending for something both improbable and contra-indicated. The day of demonstration had not yet arrived.

So it may seem now in the contemplation of the nutrient claims for simple nitrogen compounds of the sort enumerated above. There are several ways in which they may be assumed to behave in the organism. In the first and foremost instance they may serve as a pabulum for the alimentary bacteria, which in turn are destroyed in large numbers in the digestive tract and can furnish a yield of perfect protein synthesized from simple compounds like urea and the salts of ammonia. It is generally admitted that in certain species like the herbivora, in which bacterial processes have a free play in the gastro-intestinal tube, the contribution of dead bacterial bodies to the intake is by no means negligible. Small animals have actually been kept in nitrogenous equilibrium on a diet containing bacterial bodies or yeast cells as the sole source of protein in the food. The factor here referred to is one that is never easy to exclude in any discussion of nutritive values; yet it is not commonly taken into consideration.

The feeding of urea or ammonium salts might lead to an apparent nutritive advantage by depressing or inhibiting the usual breaking down of nitrogenous compounds in metabolism. This would accord with the belief that the products of cellular waste themselves tend to impede cellular metabolism. Now that the synthesis of amino-acids from ammonia and carbohydrates has been accomplished directly or indirectly in the laboratory, the possibility of a similar reaction in the body must be reckoned with. Finally, the alleged utilization of urea and other simple nitrogen derivatives may merely be an instance of unsuspected retention and delayed excretion. Even so soluble a salt as an iodid may not be entirely recovered in the excreta until several days after its administration has been stopped. Surely no one would look on the temporary deficit as an indication of nutritive "utilization" of the foreign salt.

There are, then, various alternative possibilities that must be reckoned with before we can proclaim unsuspected nutritive virtues for urea, nitrates, or other comparable simple derivatives. Foremost, undoubtedly, is the bacterial factor already described. This can be excluded only by avoiding the use of the alimentary tract itself. This prospect, involving prolonged parenteral nutrition, was not promising even in an experimental way until Henriques succeeded in devising an apparently effective mode of intravenous nutrition.[1] By this technic the Danish investigators have introduced urea and ammonium salts, with avoidance of the digestive tract, as the sole source of nitrogen.[2] The outcome has been clearly negative in failing to indicate any permanent retention of nitrogen "fed" in this form and manner. One is constrained to believe, for the present, that the reputed success of others in feeding urea, etc., as sources of available nitrogen has been due to unsuspected temporary retentions or to the inevitable participation of bacteria in converting useless compounds of nitrogen into usable forms.

Current Comment

TEACHING SEX HYGIENE IN SCHOOLS

There has been considerable discussion on the question of teaching sex hygiene in the public schools. The advantage of increased knowledge for the children, as well as the practical difficulties of presenting this subject properly, have been commented on from various points of view. There has been little effort, however, to secure an expression of opinion from those vitally interested, namely, the parents and the children themselves. For this reason, the report of the Bureau of Research of the Upper Peninsula (Michigan) Educational Association, recently issued, is of interest. This bureau was organized to make a direct study of the schools of the Upper Peninsula of Michigan, their equipment and their methods and material for study. It is at present endeavoring to discover the points of strength and weakness of the schools, as judged by the parents and others interested in them. The report just issued is divided into four sections: moral education, physical education, industrial education and general. The basis for the report is the individual opinions of 317 representative citizens. Under the first head, among many other subjects discussed, the question was asked of parents, "Do you believe that sex hygiene should be taught in the schools?" To this question, ninety-two replied "yes," while 175 opposed such instruction; six made qualified replies. Commenting on these answers, the report says that the replies indicate that patrons of schools are not ready as yet to have sex hygiene taught in the schools. "Doubtless but few teachers are qualified to teach the subject well," says the report, "and to teach it poorly would be much worse than not to teach it at all." The bureau also endeavored to get the point of view of the pupil. At Houghton, two lectures on sex hygiene were given to boys and two to girls. Some time after the lectures, the boys and girls were segregated and were asked: "Did you learn anything of value at the last lecture on sex hygiene?" Ninety boys stated that they had learned something of value and eight that they had not, while fifty-four girls regarded the lecture as of value and twenty did not. When asked: "Do you favor another lecture?" eighty-five boys were in favor of further instruction and thirteen were opposed to it, while forty-four girls were in favor and thirty were opposed to the proposition. This report emphasizes the points which have been previously brought out; until we know what should be taught pupils at different ages, until we have formulated a definite graded course of instruction and have trained teachers to give this instruction, the proposition for teaching sex hygiene in the public schools should be approached with the utmost caution. In no case should an effort be made to force such instruction on the pupils or on the community. When the parents of children are convinced, by a large majority, of the advisability of such instruction, it should be provided. Premature efforts to place such subjects on the school curriculum in advance of public opinion can only cause misunderstanding and trouble.

GAS-PIPE THERAPY GETS A SETBACK

Since the days of Perkin's Metallic Tractors, no medical fraud of the drugless type has enjoyed greater vogue or swindled more people than those devices we have facetiously referred to under the term "Gas-Pipe Therapy." There are many of the gas-pipe frauds on the market. The original was the "Electropoise," devised by one Hercules Sanche, who later elaborated his device and sold it under the name "Oxydonor," having in the meantime persuaded a not-too-exacting patent office to grant him patent rights on the egregious humbug. So profitable, apparently, did the sale of this piece of fakishness prove that many imitations appeared. First, the "Oxygenor"; then, the "Oxygenator," the latter having its name changed later to the "Oxypathor." The "Oxytonor" and the "Oxybon" were still later modifications of the same scheme. Of these the Oxypathor (Oxygenator) has been the most extensively and elaborately exploited, and the extent to which the public has been defrauded has brought forth protests from various sources. The device itself consists essentially of a piece of nickel-plated tubing filled with inert material, sealed and having attached to each end a flexible cord with a garter-like attachment at the free ends. One garter is to be attached to the wrist and the other to the ankle of the person using the Oxypathor (Oxygenator). The gas-pipe itself is put in a bowl of cold water. According to the claims of the exploiters, the patient to whom the Oxypathor (Oxygenator) is attached, is made to absorb large quantities of oxygen through the skin. So absurdly fraudulent is the Oxypathor that the public in various parts of the world has been warned against it. The Australian government has debarred the thing from the Australian continent, while the committee appointed by the British Parliament to investigate medical frauds reported:

> "Much fraud is also successfully practiced by the advertisement and sale of appliances, as alleged cures for many ailments . . . appliances alleged to supply oxygen (otherwise than by inspiration) such as the 'Oxydonor' and 'Oxygenator' are, of course, deliberate swindles, for the makers cannot be supposed to be as ignorant of chemistry and therapy as their victims."

Now comes word from Vermont that the United States government has successfully prosecuted E. L.

---

[2] Henriques, V., and Anderson, A. C.: Ueber Stickstoffretentionen bei Zufuhr von Ammoniaksalzen oder Harnstoff. Durch Versuche mit permanent-intravenöser Injcktion untersucht, Ztschr. f. physiol. Chem., 1914, xcii, 21.

Moses of Buffalo, N. Y., general manager of the Oxypathor concern. The trial, which was held in Rutland, Vermont, lasted over a week, and on Nov. 7, 1914, Moses was found guilty of using the mails to defraud. The scheme has been a profitable one. At the trial it was brought out that the Oxypathor costs $1.23; it sold for $35. Aside from the element of suggestion inseparable from the use of a mysterious, expensive-appearing and imposing-looking device, purchasers of the Oxypathor could have obtained just as valuable curative effects from an empty tomato tin with a string tied to it. As a therapeutic agent, the Oxypathor belongs in the same class as the left hind foot of a rabbit caught in a graveyard in the dark of the moon. Yet at the trial the exploiters of the Oxypathor were able to produce witnesses to testify to the curative value of their gas-pipe — and a few of the witnesses called themselves doctors! This exhibition of credulity — or, in the case of physicians, worse — is but another proof of the inherent worthlessness of testimonials. Imposing and convincing testimony would have been forthcoming long ago to prove the therapeutic efficiency of the rabbit's foot if some one had an exclusive proprietary interest in the sale of rabbit's feet.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DISTRICT OF COLUMBIA

Personal.—Dr. William Browne Carr, Washington, has been appointed deputy coroner of the District, succeeding Dr. Charles S. White, resigned, to take effect, December 1.

Preparing Red Cross Hospital Site.—The demolishing of buildings on the Seventeenth Street site for the American Red Cross Hospital has commenced. The building to be erected is to be a national memorial to the women of the Civil War.

Examination of Police Surgeons.—On November 17 examinations will be held to form a list of eligibles for an appointment to the vacancy in the Board of Police Surgeons caused by the resignation of Dr. Edmund Barry, Washington, and the vacancy in the corps of medical inspectors in schools, caused by the resignation of Dr. Wilfred M. Barton. The health department announces that all who pass this examination are eligible for appointment as third assistant resident physicians at the Asylum Hospital and by law will advance after appointment one grade every four months, progressing through the Asylum Hospital, Home for the Aged and Infirm and the Tuberculosis Hospital. They then become eligible for appointment as resident physicians to the poor and later may be appointed inspectors of schools and then members of the Board of Police Surgeons.

FLORIDA

State Board News.—Dr. Joseph Y. Porter, Jacksonville, State Health Officer, has established a branch office at St. Augustine, with Dr. Maurice E. Heck in charge.——The State Board of Health is expending $20,000 for the erection of a laboratory in Jacksonville. The board has established a bacteriologic laboratory in the Hirschberg Building, Tallahassee.

Southern Health Exhibit.—Preliminary arrangements for the Southern Health Exhibit, to be held in Jacksonville in connection with the convention of the American Public Health Association the end of November and the first few days of December, are practically completed. Most of the larger cities of the South have arranged for their exhibits, and will furnish statistics and evidence of an educational nature to show the progress of health conditions in each community.

Hospital Corner-Stone Laid.—The corner-stone of the Pensacola Hospital was laid with fitting ceremonies, October 11. The building will cost about $400,000, will be five stories in height, with a frontage of 212 feet and a depth of 187 feet, and will contain accommodations for 100 patients.——The Escambia County Medical Society gave a dinner to the Sisters of Charity at San Carlos Hospital, San Carlos, after the ceremonies, at which the Hon. W. A. Blount acted as toastmaster.

ILLINOIS

Meeting of the Federation of Charities.—At the meeting of the Illinois State Conference of Charities and Correction held at La Salle, October 24-28, Dr. George T. Palmer of Springfield was elected president. Danville was selected as the place for the next meeting.

Meeting of Illinois State Tuberculosis Association.—At the meeting of the Illinois State Association for the Prevention of Tuberculosis at La Salle, October 28, the attitude of Governor Dunne in placing the embargo against the importation of tuberculous cattle in Illinois was commended and the association pledged itself to the repeal of the Shurtleff law, which deprives cities of the right to require the tuberculin testing of dairy cattle. The following officers were elected: president, Dr. George T. Palmer, Springfield; vice-president, Dr. Charles W. Lillie, East St. Louis, and Dr. Samuel Dodds, Cairo; secretary, James Minnick, Chicago, reelected.

Chicago

German War Dinner.—The German Medical Society held a "War Dinner" at the Hotel LaSalle, October 24, at which Dr. Maximilian Herzog narrated his experiences in his recent trip to the war zone, and Dr. Paul Carus made an eloquent plea for peace.

Appreciation of Service.—At a largely attended dinner at the Sherman Hotel, Chicago, November 9, the Chicago Pathological Society presented Dr. George Howitt Weaver with an appropriate testimonial of its appreciation of his efficient services as secretary of the society for twenty consecutive years. Short addresses were made by Dr. J. B. Herrick, Dr. W. E. Quine and Dr. L. Hektoen; Dr. Weaver responded.

Lying-In Hospital Opens Pavilion.—The recently completed Mother's Aid Pavilion of the Chicago Lying-In Hospital was opened for inspection October 30, when a reception was tendered by the directors to nurses and physicians of Chicago. The pavilion is a four-story brick building constructed at a cost of $85,000 and has accommodations for thirty patients, one-third of whom will be charity cases. The hospital was opened to the public November 3.

INDIANA

Antituberculosis Society Organized.—Clark County Society for the Study and Prevention of Tuberculosis has been organized at Jeffersonville. The society will control the funds raised by the sale of Red Cross seals and expects to institute public nursing and medical inspection of school-children.

Malpractice Suits Decided in Physicians' Favor.—In the malpractice suit brought by Harold Shana, Glenwood, for $15,000 against Drs. Hugh H. Elliott and Eli John Q. Paxton, both of Rushville, in which the plaintiff alleged that he had been treated for rheumatism when he really had a fracture, it was proved that the physicians had treated him for fracture and the suit was consequently decided in favor of the physicians. The father of the plaintiff sued the same physician a few weeks ago for $5,000 damages and the suit was decided against him.

Personal.—Major M. August W. Shockley, M. C., U. S. A., has been assigned as inspector and director of the National Guard of Indiana, Ohio, Kentucky, Michigan and West Virginia.——Dr. Charles A. Pfafflin, Indianapolis, has returned from abroad.——Dr. Marshall T. Shively, Marion, has resigned as a member of the board of public works on account of ill health.——Dr. Onis O. Melton, Hammond, who was operated on at the Augustina Hospital, Chicago, recently, has returned home convalescent.——Dr. Oscar E. McWilliams, Anderson, is reported to be ill at his home with pneumonia.

IOWA

Milk Laboratory Ready.—City Physician E. D. Middleton of Davenport announced on November 3, that the milk-testing equipment, recently ordered, had been installed and was ready for the use of the public.

KANSAS

Personal.—Dr. H. Michener, Wichita, as the result of Roentgen-ray burns, had his ring finger amputated October 21. This is the second operation and it is probable that another finger will have to be removed.——Dr. Thomas C. Long, Independence, was seriously injured in an automobile accident near Independence, October 29.——Dr. John W. Hains, Kansas City, suffered a compound fracture of the right leg and internal injuries by the overturning of his automobile near Vance, November 2.

MARYLAND

Medical Librarian Appointed.—Mrs. Ruth Briscoe has been appointed librarian of the medical department of the University of Maryland, Baltimore. The library now contains more than 11,000 volumes.

Stamp Vending Profits to Tuberculosis Sufferers.—The Maryland Association for the Prevention and Relief of Tuberculosis, in order to raise funds for the support of its work, has adopted the sale of stamps by an automatic stamp vending machine, in which two 2-cent stamps are sold for 5 cents, the extra cent going to the relief fund of the association.

Personal.—Dr. John F. Spearman, formerly of Baltimore, is on duty with the German forces near Strasburg.——Dr. Veader N. Leonard, Baltimore, who left on the first Red Cross expedition, is on duty at a 300-bed war hospital at Paignton, New Devonshire.——Dr. Eleanor B. Wolf, Baltimore, has sailed for India where she will be a member of the medical staff of the Guntur Hospital.——Dr. Henry Key is reported to be seriously ill with double pneumonia at the Hotel Altamont, Baltimore.

Semi-Annual Meeting of Faculty.—The semi-annual meeting of the Medico-Chirurgical Faculty of Maryland was held October 28 and 29 at Upper Marlboro and addresses were made by Dr. Randolph Winslow, Baltimore, president of the faculty, and Dr. Henry B. McDonnell, College Park, president of the Prince Georges' County Medical Society. A tablet was erected to Dr. William Beans, one of the founders and organizers of the faculty. Public meetings and a health exhibit were held under the auspices of the public instruction committee of the faculty during the meeting.

Sanatorium Opened.—The Pine Bluff Sanatorium near Salisbury, Wicomico County, a state institution for the treatment of advanced and chronic tuberculosis cases, has been formally opened. Dr. George W. Todd is superintendent of the institution and a special feature of the treatment is the single apartment system for patients. The institution can now accommodate forty patients, but within the next year will double its capacity. Indigent persons suffering from tuberculosis are admitted to the institution without charge on certificate of a reputable practitioner.

Hopkins Physicians Honor Their Dead.—At the twenty-fifth anniversary of the Johns Hopkins Medical School, tablets set in the walls of the hospital were dedicated to the honored dead. One of these tablets was in memory of Dr. John Hewetson who was assistant resident physician at the hospital from 1890 to 1894. Another in the lobby of the main hospital building is inscribed with the name of the late Dr. D. C. Gilman, first president of the university, with that of Dr. James W. Lazear of yellow fever fame and with that of Dr. Rupert Norton who died a short time ago while assistant superintendent of the institution.

MASSACHUSETTS

Free Mental Clinics.—Members of the staff of the Northampton and Monson state hospitals will hold a free clinic at the Springfield Academy of Medicine, Wednesday afternoons from 2 to 5 o'clock, at which they will see persons suffering from nervous disorders, worry, anxiety, mental disorders, incipient or fully established mental diseases or epilepsy.

Mental Hygiene Society Opens Office.—The Massachusetts Society for Mental Hygiene has opened an office at Room 313, Ford Building, 15 Ashburton Place, Boston. The officers of the society are: the Hon. Harvey H. Baker, Boston, president; Dr. Walter E. Fernald, Waverly, vice-president; Dr. Charles E. Thompson, Gardner, secretary; John Koren, Boston, treasurer, and Dr. Frankwood E. Williams, formerly of Ann Arbor, Mich., first assistant physician at the Psychopathic Hospital, Boston, has been appointed executive secretary.

Hospitals for the Insane to Keep Physicians on the Premises Constantly.—The Massachusetts State Board of Insanity has voted that each private licensed hospital under the supervision of the board having five or more committed patients, beginning October 1, shall have a physician on the premises constantly, and that private licensed hospitals having less than five patients, committed or not, shall, from the same day, have a resident physician who shall see each patient at least once every day; also that no private hospital shall keep mental patients on the third floor of any building without special permission in writing from the State Board of Insanity.

Personal.—A banquet was given to Dr. Charles F. McCaffrey, Somerville, recently appointed medical examiner, by citizens of that city and after the banquet a fur coat was presented to Dr. McCaffrey on behalf of those present.——Dr. Allen J. McLaughlin, U. S. P. H. S., assumed the duties of his office as health commissioner of Massachusetts, November 2.——Drs. Ernest P. Miller and Bernard W. Carey, Fitchburg, have returned from abroad.——Dr. Theodore S. Bacon, Springfield, has resigned as associate district medical examiner.——Dr. Karl R. Bailey has been appointed bacteriologist to the Boston Health Department.——Dr. Henry P. Walcott, Boston, has been reappointed chairman of the Metropolitan Water and Sewerage Board.——Dr. Augustus L. Chase, Randolph, has been reappointed a member of the Board of Registration in Medicine.

MISSISSIPPI

Special Sanitary Officer Wanted.—As the result of the propaganda of the Pure Milk Committee of Forrest County, efforts are being made to secure a full-time health officer for the county at a salary of $1,800 per year.

Personal.—Dr. Walter H. Rowan, who resigned as State Sanitary Inspector, to take effect November 15, was presented with a gold watch fob by the members of the Mississippi Public Health Association at its meeting in Jackson, October 28. Dr. Rowan has been appointed chief sanitary officer of the Republic of Costa Rica, and will also work under the auspices of the Rockefeller Foundation.——Dr. Willis Walley, Richton, has been appointed state sanitary inspector in place of Dr. Rowan.

MISSOURI

Personal.—Dr. Daniel R. Hill, commissioner of health and sanitation of Joplin, has been chosen chairman of the Joplin Board of Health, and Dr. Alonzo L. Carpenter, city physician, has been elected secretary.——Dr. William Boyd Hight, Queen City, was seriously injured by the overturning of his automobile, October 19.

St. Louis

Appointments of City Hospital.—Director of Public Welfare Tolkacz has announced 133 appointments on the visiting staff of the St. Louis City Hospital and municipal institutions, October 30. The appointments are divided into three classes: the first is composed of the nominees by the Washington University; the second nominees by St. Louis University, and the third nominees by the National University and appointments without regard to university connection.

Hospital Dedication.—The Barnes Hospital, erected and equipped under the terms of the will of the late Robert A. Barnes, who bequeathed $1,000,000 for its purpose, the balance of his estate being held as an endowment, was dedicated with impressive ceremonies, October 27. The dedicatory address was made by Bishop Hendricks of the Methodist Episcopal Church, South, who also unveiled a bronze bust of Robert A. Barnes. Washington University, with which the hospital is affiliated, was represented by its president and by Dr. George Dock, medical director.

NEW JERSEY

Personal.—Dr. Alonzo L. Leach has been elected president and Dr. Virgil M. D. Marcy, Jr., health inspector of the Cape May Board of Health.

NEW YORK

Medical Clubhouse Opened.—The Rochester Medical Society opened its new clubhouse for public inspection, November 4, and held an informal reception from 4 in the afternoon until 10 in the evening. The building is in colonial style and accommodates a medical library, a dining-room, an assembly room for the society and one for the Blackwell Medical Society. The property was purchased in June for $35,000 and the building has been remodeled and fitted for its present uses.

Quarantine Against Foot-and-Mouth Disease.—An order quarantining New York state against foot-and-mouth disease was issued on November 7 by the commissioner of agriculture, to become effective November 9. Another order prohibits the transportation of cattle from Canada into this state and another will forbid the feeding of skimmed milk and whey to calves and pigs in districts in which the disease exists. The quarantine will mean that there can be no movement of animals from one county to another until the animals have been inspected and a permit issued.

Health Exhibits at State Fair.—During August and September the State Department of Health had exhibits at fifty-three county fairs and 575,000 people had the opportunity of seeing them. In addition to these fairs the exhibits have been shown at the state fair, Syracuse and the Rochester Industrial Exposition, which have a combined attendance of 750,000. Five child welfare and three rural sanitation exhibits have been used at these fairs and the routes have extended from the St. Lawrence to Rockland county and as far west as Chautaqua and Niagara counties. The interest in the child welfare campaign has been extended to the county fairs and many more requests for the exhibits were made than could be granted.

Personal.—A reception was given at the Adirondack Cottage Sanatorium, Saranac Lake, October 28, for Dr. and Mrs. Francis B. Trudeau, Dr. and Mrs. M. Lawrason Brown, and Dr. and Mrs. Frederick H. C. Heise.——Dr. Regina Flood Keyes, Buffalo, sailed from New York, October 31, to join the staff of the American Ambulance Hospital, Paris.——Dr. Charles C. Kimball has been appointed a member of the board of health of Watertown, vice Dr. Olmsby O. Stowell, resigned after serving as a member of the board for fourteen years and as its president for seven years.——Dr. John L. Heffron, dean of the College of Medicine of Syracuse University, has been appointed a member of the advisory medical council of the state university for a term of five years.——Dr. Frederick Luke Classen has been appointed attending physician in connection with the state insurance fund of the compensation department with office at Albany.

New York City

New Clinic for Cripples Opened.—The new dispensary in connection with the Hospital for Deformities and Joint Diseases, of which Dr. Henry W. Frauenthal is surgeon in chief, was dedicated on November 3. The new dispensary is a six-story building which with its site cost $130,000, of which amount all but about $10,000 has been paid. A gift of $1,000 from the Young Ladies' and Gentlemen's League was announced at the dedication. Among those who made addresses on this occasion were Dr. Abraham Jacobi and Dr. Katherine Davis.

Gift to University.—A gift of $113,750 from William K. Vanderbilt has enabled Columbia University to take title to the north half of the block bounded by 116th and 117th streets, Amsterdam Avenue and Morningside Drive. This property was acquired as a site for the new medical school, but the amalgamation of the College of Physicians and Surgeons and the Presbyterian Hospital has so modified the plans of the medical school that it has been decided to await further developments. The site is now occupied by the temporary building which houses the Crocker Research Laboratory.

Revising the Sanitary Code.—A letter has been addressed by the commissioner of health to each member of the advisory council and the medical advisory board announcing that a general revision of the sanitary code has been undertaken, with the purpose of bringing the code into conformity with the great body of municipal ordinances recently remodeled by the codification committee of the board of aldermen. It is pointed out that this occasion affords an opportunity for improving the code by the redrafting of existing sections, by the omission of superfluous contents, and by the inclusion of desirable new matter.

Society for Clinical Study.—The annual meeting of "The Society for the Advancement of Clinical Study" of New York City, will be held at the Academy of Medicine, 17 West Forty-Third Street, on Wednesday afternoon, November 18, at 5 p. m. This society, organized for the purpose of maintaining a bureau of information, will furnish to resident and visiting physicians definite information regarding the clinical facilities of the hospitals and laboratories of the city of New York. A bulletin board has been installed at the Academy of Medicine in charge of a special clerk, and on this all hospital clinics, both medical and surgical, are posted daily.

New Appointments at Columbia University.—It has been announced that clinical instruction for the medical students of the College of Physicians and Surgeons is hereafter to be provided at the Montefiore Home and to carry on this instruction the following appointments have been made: Dr. Siegfried Wachsmann, Berlin, professor of clinical medicine; Drs. George L. LaPorte and Simon Philip Goodhart, assistant professors of clinical medicine; instructors in laryngology, Dr. Arthur P. Goll and Dr. John Leshure. Dr. Warfield T. Longcope was appointed to serve as a member on the board of managers of the George Crocker Special Research Fund.

Enforcing the New Milk Regulations.—During September eighty dairies were excluded from business in this city for failure to comply with the minimum requirements for the production of Grade "C" milk. Shipments from four creameries were ordered degraded from Grade "B" to Grade "C," as the bacterial content of the milk shipped from two of these creameries was found to be continually excessive, and the other two were ordered degraded because of improper pasteurizing apparatus. Samples for bacterial examination were taken at forty-four pasteurizing stations during the month. Their examination showed that the process of pasteurization was conducted in a very satisfactory manner, and that in all but nine the regulations were being closely followed. Eleven new pasteurizing plants have been approved during the month. Nearly 24,000 specimens of milk as offered for sale in the city were examined and of this number only sixty-three were found to be above the maximum temperature permitted by the department's regulations. In addition 579 samples of raw milk were taken and on chemical analysis ninety-nine were found to be below the standard.

Personal.—Dr. H. McDonald Peggs has gone to Europe to make a reconnoissance in the war zone for the British Imperial Club. He goes first to England and then to the front to learn what surgeons, nurses and supplies are needed. The club will send what is recommended. Dr. Peggs then expects to work in the British hospital corps.——Dr. John Ravenswood Hicks, New Brighton, has accepted Dr. Hermann M. Biggs' request to help organize local health work on such lines as promise a maximum return for a given amount of money expended. Dr. Biggs believes that before such an adjustment can be effected it will be necessary to secure some uniformity in health department accounting, so that the expenditures for various purposes in various communities may be fairly compared.——Dr. E. C. Baldwin of Ft. Wadsworth, bacteriologist and director of the old laboratory at the Quarantine Station, has resigned in favor of Dr. Oscar Teague, recently of Cornell.——Dr. William E. West was seriously injured in a collision between his touring car and an Erie train at a grade crossing near West Haverstraw, N. Y., November 2.——Dr. John Herman Branth and family narrowly escaped death in the burning of his gasoline launch in the Hudson River, October 19.

OHIO

Small-Pox on Ore Steamer.—The steamer *William P. Palmer* left Conneaut on October 17 for Duluth. One of the crew left behind at Conneaut developed small-pox the same day. The remainder of the crew were vaccinated at Duluth and the cabin in which the patient had slept was disinfected. On the return of the steamer to Conneaut, October 25, she was placed in the hands of the State Board of Health by her owners, the Pittsburgh Steamship Company. Permission was given to unload her cargo. The crew was then revaccinated and the steamer laid up at the dock with sanitary policemen to prevent the crew from leaving. No further cases of small-pox have developed and the period of quarantine expires shortly.

Conference of State with Local Boards of Health.—The fortieth conference of the State Board of Health with representatives of local boards of health was held in Cincinnati on Oct. 22-23, 1914. The attendance at the three sessions averaged about 250. The first session was devoted to a discussion on rural hygiene. Mr. John W. Hill, president of the state board, spoke of measures to prevent stream pollution. The chief engineer dealt with public improvements in villages from the standpoint of the sanitarian, and Dr. Paterson and Miss Britton discussed various phases of public health nursing. The evening session was devoted to illustrated lectures by Drs. Emery R. Hayhurst and Frank G. Boudreau, Columbus, on occupational diseases and communicable diseases, respectively. The third and final session was devoted to a discussion of model rules and regulations for villages and townships, rural school sanitation, and the relation of the rural health officer to his city brother. Dr. Eugene F. McCampbell, secretary and executive officer of the board, brought the session to a close by his discussion of proposed public health legislation. The most important measure he discussed was that dividing the state in large health units, each under the care of a full-time trained health officer.

Cincinnati

Work Cure for Convalescents.—The Cincinnati Hospital Board has adopted the work cure for convalescents and work rooms will be established as soon as the institution is opened. Among the work to be inagurated will be basket weaving and rug making.

Personal.—Dr. Arthur C. Bachmeyer, superintendent of the Municipal Tuberculosis Sanatorium, has been appointed superintendent of the Cincinnati General Hospital, succeeding Dr. Charles F. Sanborn, resigned.——Dr. Walter E. List retains his post as assistant superintendent of the hospital and Dr. Harry Freudenberger has been appointed assistant in charge of the Tuberculosis Sanatorium.

Holmes Honored by Staff.—At a meeting of the staff of the Cincinnati General Hospital, October 29, resolutions were unanimously adopted approving of the new Cincinnati General Hospital and recognizing the faithfulness, efficiency and self-sacrificing devotion of Dr. Christian R. Holmes, "the one man chiefly instrumental in bringing the construction of the institution to a successful conclusion."

New Hospital Plans.—In accordance with the plans of the mayor and Dr. Christian R. Holmes, safety director, the Tuberculosis Sanatorium and General Hospital will be placed under one head who will receive a salary of $5,000 a year. Each hospital will have an assistant superintendent with a salary of $2,000 a year and the payroll of the General Hospital will amount to about $150,000. It is expected that the hospital will be ready for opening January 1.

PENNSYLVANIA

County Medical Society Building.—Plans have been completed for the new building of the Luzerne County Medical Society, and work has already begun. It is a fireproof structure of brick and stone, and will cost about $20,000.

Personal.—Dr. Robert G. Boak, Newcastle, was seriously injured in a collision between his automobile and the upright supports of a railroad crossing.——Dr. William D. Danner, Glenville, who was operated on October 10 at the West Side Sanitarium, York, returned home convalescent a week later.——Dr. Henry J. Benz has succeeded Dr. Henry B. Burns as superintendent of the Bureau of Child Welfare of Pittsburgh.——Dr. Harry W. Salus, Johnstown, has been appointed state medical inspector for Cambria County in the Department of Labor and Industry.

Scarlet Fever, Diphtheria and Typhoid.—Between October 1 and 29, 241 cases of scarlet fever were reported in Pittsburgh. Twenty-seven cases of virulent scarlet fever with three deaths are reported from Donora, Washington County, and twenty-five cases from Blue Ball, Lancaster County. Schools have been closed at Confluence, Somerset County, and New Florence, Westmoreland County, on account of scarlet fever. In Pittsburgh, 120 cases of diphtheria were under quarantine October 29. The Pittsburgh Department of Public Health has been distributing antitoxin at low prices. Since the first of the year, 23,718,000 units of antitoxin have been distributed at a cost of almost $10,000. In Monessen, Westmoreland County, fifty-nine cases of typhoid were reported October 29.

Philadelphia

Society Anniversary. — The Philadelphia Neurological Society announces that it will celebrate the thirtieth anniversary of its foundation by holding a special scientific meeting on November 27, followed by a banquet on November 28.

Meat Laws Affected.—Several new regulations relative to the sale of meats have recently become effective, the most important of which is the rule which governs the sale of meat of animals affected with disease. The parts not affected may be sold only after a process of sterilization and cooking and canning and marked "Second class meat, sterilized."

The Alvarenga Prize: Correction.—In a notice sent by the College of Physicians and Surgeons of Philadelphia regarding the award of the Alvarenga prize, which appeared in The Journal of November 7, page 1680, the title of the essay for which Dr. Herman B. Sheffield was awarded the prize, should have been "Idiocy and Allied Mental Deficiencies in Infancy and Early Childhood."

Stockyards Under Quarantine.—As a preventative measure against the spread of foot-and-mouth disease among cattle, a quarantine was placed November 7 on the stockyards. While the disease had not appeared among the cattle there, the animals on hand came from Chicago and other infected districts. On November 9 inspectors made a canvass of all farms within a 10-mile radius of the city.

Police Orders to Aid Sick.—Among the new orders issued to the police are regulations requiring that women accompanied by babies or small children be sent in patrol wagons to the city hall or county prison and not in police vans, that a physician accompany a woman removed from her home to the police station and a hospital in a patrol wagon and that a police matron be sent with abandoned infants who are removed to the Philadelphia Hospital.

Personal.—A smoker was given by the Philadelphia County Medical Society at the University Club on October 28, in honor of Dr. John B. Deaver.——On the occasion of the seventy-eighth birthday of Dr. Daniel Baugh, October 22, the medical and legal professions of the city joined in doing honor to the founder of the Daniel Baugh Institution of Anatomy. Practically the entire faculty of the Jefferson Medical College and the entire staff of the Jefferson Hospital were present.——Dr. Charles J. Hatfield has been elected executive secretary of the National Association for the Study and Prevention of Tuberculosis to succeed Dr. Livingston Farrand, New York, resigned.——Dr. Frank H. Hustead has been elected surgeon-general to the Association of Soldiers of Foreign Service of the United States.——Dr. William Penn Vail was elected by the Philadelphia County Medical Society to fill the unexpired term of assistant secretary of the board of directors, vice Dr. Arthur H. Hopkins, resigned.

RHODE ISLAND

Dr. Peters' Work Recognized.—In recognition of the twenty-five years of service as superintendent of the Rhode Island Hospital of Dr. John M. Peters, nearly two hundred physicians of the state gathered at the Turks' Head Club, Providence, October 28, at a dinner in honor of Dr. Peters. Dr. G. Alder Blumer, superintendent of Butler Hospital, officiated as toastmaster. Addresses were made by Dr. Herbert B. Howard, superintendent of the Peter Bent Brigham Hospital, Boston; Hon. Charles C. Mumford, who spoke in behalf of the trustees and the general community, and Dr. Jacob C. Rutherford, who on behalf of the medical profession of the state, presented Dr. Peters with a gold watch and chain.

VIRGINIA

Personal.—The home of Dr. Samuel H. Price, Montvale, was destroyed by fire, October 16, with a loss of about $8,000, partially covered by insurance.——Former President S. C. Mitchell of the Medical College of Virginia, Richmond, delivered the principal address at the anniversary of the surrender of Yorktown, October 20.

Tuberculosis Camp Without Funds.—The management of the Pine Camp Tuberculosis Hospital announces that unless the city of Richmond takes over the management of the institution, it will be necessary to close it this month, and the thirty-six patients in an advanced state of tuberculosis will either be left destitute or must be cared for by some other charity.

Alumni Association Organized.—A University of Virginia Alumni Association has been recently organized to bring together the alumni of the university and to further the interests of the school in the South. The following officers have been elected: Dr. Hugh H. Young, Baltimore, president; Dr. John Staige Davis, University, vice-president; Dr. Seale Harris, Mobile, Ala., secretary; Dr. Thomas V. Williamson, Norfolk, treasurer.

Malarial Survey of the State.—Surgeon Rudolph H. von Ezdorf, U. S. Public Health Service, has completed a malarial survey of Virginia, and reports that he has located breeding places of the malarial mosquito and has taken steps toward their eradication. The next step of the work is the determination of how many people are carrying malaria in their blood, while the third part of the work is educational. The State Board of Health proposes to do a considerable amount of educational and eradicatory work during the year.

State Society Meeting.—The Medical Society of Virginia held its forty-fifth annual meeting in Washington, D. C., October 27 to 29, under the presidency of Dr. Stephen Harnsberger, Catlett. Dr. Harnsberger and Surgeon-General William Crawford Gorgas, M.C., U. S. Army, were elected honorary members of the society, and the following officers were elected: president, Dr. Samuel Lile, Lynchburg; vice-presidents, Drs. Samuel B. Moore, Alexandria; Joseph T. Buxton, Newport News, and John W. Preston, Roanoke; secretary, Dr. Paulus A. Irving, Farmville (reelected); treasurer, Dr. Mark W. Peyser, Richmond (reelected); delegate to the American Medical Association, Dr. Robert C. Bryan, Richmond, and alternate, Dr. Sparrell S. Gale, Roanoke. Richmond was selected as the next meeting place.

GENERAL

Tri-State Physicians to Meet.—The Tri-State Medical Association of Virginia and the Carolinas will hold its seventeenth annual meeting at Charleston, Feb. 17 and 18, 1915, under the presidency of Dr. Edward C. Register, Charlotte, N. C.

Ohio Valley Physicians Hold Meeting.—At the sixteenth annual meeting of the Ohio Valley Medical Association held in Evansville, Ind., November 4 and 5, the following officers were elected: president, Dr. E. Otis Smith, Cincinnati; vice-presidents, Drs. George M. Young, Evansville; William Shimer, Indianapolis, and William M. Harsha, Chicago; secretary-treasurer, Dr. Benjamin L. W. Floyd, Evansville (reelected).

Bequests and Donations.—The following bequests and donations have recently been announced:

The Sisters of Charity (colored), of Indianapolis, have raised nearly $10,000 for the purchase of property on which a hospital is to be erected for the exclusive use of colored people.

Jewish Hospital, Pennsylvania Institution for the Instruction of the Blind, Wills Eye Hospital, Pennsylvania Hospital, and Presbyterian Hospital, Philadelphia, each $5,000 by the will of Henry B. Palethorp.

University of Pennsylvania, $50,000; Hospital of the Protestant Episcopal Church, Philadelphia, $10,000; Children's Aid Society, Philadelphia, $10,000; and Pennsylvania Prison Society, Philadelphia, $10,000, by the will of Miss Anna M. Blanchard.

German Society, $5,000, for the endowment of a free bed in the German Hospital, by the will of William Lutz.

First-Aid Cars.—Dr. Matthew J. Shields, Scranton, Pa., one of the staff of the American Red Cross Aid Department, with First-Aid Car Number 3, arrived at the Terminal, Washington, D. C., November 4, and lectured on November 5 in the car to the employees of the Washington Terminal Company on "Accident Prevention and First Aid." The car was then taken to Richmond, Va., where Dr. Shields lectured, November 6. First-Aid Cars Numbers 1 and 2 are touring the United States the year round, giving free lectures to workman in shops, factories, mines, etc., on "Accident Prevention and First-Aid Methods."

To Reduce Death in Mines.—As the result of a report by the committee of physicians, consisting of Dr. Walter B. Cannon, Harvard University, chairman; Drs. George W. Crile, Cleveland; Joseph Erlanger, St. Louis; Dr. Yandell Henderson, Yale University, and Dr. S. J. Meltzer, Rockefeller Institute for Medical Research, recommendations have been made by the Bureau of Mines regarding methods used by miners in resuscitating fellow workmen overcome by electric shock or gases in places that cannot easily be reached by physicians. These recommendations applied equally well to individuals suffering from the effects of illuminating gas poisoning or electric shock.

Holiday Gifts for Culion Lepers Requested.—Dr. Victor G. Heiser, United States Director of Health in the Philippines, suggests that Americans send some little kindly token of sympathy next Christmas to the Culion lepers. Readers who wish to remember the lepers should do so at once, because it requires several weeks to reach the Culion leper station. Send prepaid parcels, checks or money orders to Mr. Fleming H. Revell, 158 Fifth Avenue, New York City, treasurer of the U. S. A. Committee, the Mission of Lepers, who has consented to receive and forward all gifts. All parcels should be securely wrapped, marked and addressed, also bearing the name of the sender.

Red Cross Work in France.—Following up its recent donation of $25,000 to the American Ambulance Hospital, Paris, the American Red Cross has asked Ambassador Herrick if he will receive $10,000 to be used at his discretion in furnishing surgeons, nurses, supplies, or whatever is most needed in Vierzon, Dinard, Dieppe and Pau, from which points appeals for assistance have come. It is said that there are 1,200 gravely wounded French and German soldiers in Vierzon, and at Boulogne there are 400 wounded lying on straw, with only one surgeon, an American, to attend them.——The American Red Cross arranged on November 4 to ship 5,000 heavy blankets to distressed non-combatants in Belgium.

The Foot-and-Mouth Epizootic.—The Chicago stockyards were closed for a ten-day period at the end of the day, November 5, by the Illinois Live Stock Commission in the attempt to check the epidemic of foot-and-mouth disease now affecting six states. No cattle will be permitted to be shipped to or from the yards. Cattle already shipped from the uninfected areas which reached the yards by 5 p. m. November 5 were to be admitted, but after that hour none were to be received until the yards and buildings had been thoroughly fumigated and disinfected and the quarantine lifted. The stockyards of Buffalo, New York and Indianapolis have been quarantined and New York, Maryland, Indiana, Michigan, Illinois, Pennsylvania, Wisconsin and Ohio and other states have also been quarantined by the federal authorities. Interstate shipments of cattle, sheep and swine are prohibited from the states now quarantined. The United States Department of Agriculture has pronounced the epidemic the most virulent and dangerous the country has ever experienced. It is probable that Congress will be asked for an appropriation to suppress the disease.

The Small-Pox Situation in the Middle West.—Under the policy of resistance by the Dowieite community in Zion City, Ill., to the efforts of the Illinois State Board of Health, the number of cases of small-pox in that place has increased to nearly fifty. November 3 the overseer of the community under protest consented to allow the state authorities to take charge of the situation. Dr. C. E. Crawford, medical inspector for the Illinois State Board of Health, at once instituted a rigid quarantine on the premises of all persons affected with small-pox and appointed six deputy inspectors to assist him in maintaining quarantine. He also prohibited all public gatherings, canvassing from house to house, and ordered all children under 16 years of age to remain at home. All the inhabitants who are willing are being vaccinated. Under the law the Illinois State Board of Health has no power to compel vaccination. The surrounding towns have already declared a rigid quarantine against Zion City. Some manufacturing establishments in Waukegan, Ill., have been closed down on account of the threatened spread of the disease. The number of cases at Neponset, Ill., has increased to thirty, and schools and churches have been compelled to close temporarily.——Forty cases of small-pox were reported from Whiting, Ind., November 2. The health authorities are said to have the situation in hand now. Fifty cases are reported from Cromwell, Noble County, Ind., by J. W. Moore, county health officer.——Forty-four cases of small-pox were reported in Milwaukee, Wis., October 28, and the commissioner of health believes that many cases of the disease in mild form have not been reported.——There have been six cases in Battle Creek, Mich. Cases are also reported from Allegan, Mich. Nineteen cases of mild small-pox, at first diagnosed as chicken-pox, are reported from Manistee County, Michigan, near Kaleva. Two schools have been closed and an area of 10 square miles is under quarantine. Six cases are reported from Escanaba, Mich., and nearly twenty cases from Alamo, Mich. The disease throughout the West seems to be present in a mild form.

WAR NOTES

Cholera in Galicia.—It was officially announced in Vienna, November 6, that there are 256 cases of cholera in Galicia of which 126 are reported from Przemysl.

American Surgeons Appreciated.—A dispatch from London states that the American hospitals at Gleiwitz and Cassel are doing such satisfactory work that the government is about to request that three more American surgeons be sent to Germany.

Aid for Non-Combatants.—In addition to the supplies sent to Belgium, which were noted in The Journal of last week, the American National Red Cross has cabled $10,000 to Minister Van Dyke at the Hague for Belgium refugees in Holland and has also sent a number of boxes of clothing for women and children and 500 pairs of blankets.

Mikado Gives Money for Hospital.—Emperor Yoshihito has given $25,000 toward the foundation of St. Luke's International Hospital, Tokyo, to be conducted under the auspices of the Protestant Episcopal Church. The institution is to be the most elaborate in the far east and will cost about one-half million dollars. The substantial imperial support will, it is believed, assure the success of the enterprise.

More Medical Aid from the United States.—Mrs. Harry Payne Whitney sailed for Europe on the *Lusitania* November 4, with a staff of four surgeons and fifteen trained nurses to establish a field hospital in northern France. Ten motor ambulances and a large quantity of medical supplies and clothing sufficient for 3,000 men, women and children were shipped to France by Mrs. Whitney, October 31. The surgeons who accompanied Mrs. Whitney are Drs. Walton Martin, New York City, in charge of the field organization; Drs. Karl Connell and Donald Gordon, New York City; Dr. W. E. Drennan, Birmingham, Ala.

Prize Given for Relief Work.—The Société Médicale des Hôpitaux de Paris appointed last summer a delegate to the sixth congress of the Association of French-Speaking Physicians in North America, which was announced to be held at Quebec, August 31 to September 3. At the same time it notified the association that it would give a prize of $200 for the best paper read at the meeting. In acknowledging this courtesy the executive committee, writing August 2, expressed their appreciation but said that as the cable had just brought word that war was declared in Europe they suggested that the munificent offer for a prize be devoted instead to the relief of the wounded in the war. This has been done, the society turning over to the fund for the aid of the wounded five-fold the amount designated for the prize.

PARIS LETTER

Paris, Oct. 22, 1914.

Hygiene in War

At the last meeting of the Parisian section of the Association générale des hygiénistes et techniciens municipaux, Dr. Frederic Bordas, temporary professor at the Collège de France, suggested a number of ingenious devices for use in war time.

It is not always easy to procure hot water for baths, dressings or hot drinks in a temporary hospital. In the country, one may take one of those steam engines used to supply power on farms. The steam from the generator is turned with free escapement into a barrel or other water-container and in a few minutes the temperature of the water is raised to the boiling-point. This sterilized water may be used for washing wounds or for drinking. When the temporary hospital is near a factory, a jet of steam from the boiler will answer the same purpose.

To protect soldiers from the cold, the Japanese, during the war in Manchuria, used paper clothes made from rice-straw or bamboo. This paper, though proportionately expensive, gives very good results. Equally good results have been obtained from wrapping-paper rendered impermeable by being lightly greased with liquid petrolatum and used as an interlining between two layers of cloth.

The secretary of the Association des Hygiénistes et techniciens municipaux, M. Samuel Bruère, chemist of the laboratory of toxicology, recommends, for the sterilization of the soldier's drinking-water, to be done by the soldier himself, the use of: (1) 0.25 gm. tablets of calcium glycerophosphate and potassium phosphate with 7 mg. of potassium permanganate; (2) tablets of 0.5 gm. of citric acid with the precise quantity of sodium hypophosphite to reduce the excess of permanganate. Each soldier could easily be supplied with a little box or metal case containing a certain number of these tablets and thus could himself sterilize the amount of water he needs for his own use. In each liter (quart) he would drop a pink tablet (potassium permanganate) then five minutes afterward a white tablet (sodium hypophosphite). Numerous practical trials with yellow and turbid Seine water have proved that a dose of 7 mg. of potassium permanganate per liter in contact for five minutes in the presence of calcium glycerophosphate is sufficient to eliminate the colon bacillus. At the end of five minutes, the addition of the second (hypophosphite) tablet reduces the excess of permanganate in nine or ten minutes. From violet the water becomes citron yellow. A little while later it loses color. At the end of ten more minutes, the color is hardly perceptible, and it disappears completely in twenty minutes, leaving no trace of the yellowish color of the untreated water. The treatment requires altogether not more than twenty-five or thirty minutes.

A New Military Hospital in Paris

The Grand-Palais is now used by the military health service, which has established there a hospital remarkable for the vast extent which it occupies and for its situation, one of the most attractive in Paris. The hospital was opened October 13 by Dr. Février, director of the military health service. With the aid of M. Deglane, architect of the Grand-Palais, the immense exposition galleries have been rapidly transformed into hospital wards at slight expense. The hospital has 1,200 beds and receives convalescents especially. Some wards have been furnished by the French Red Cross, others by the proprietors of some large mercantile establishments in Paris and others with material belonging to the military health service.

The Blue Cross

Mme. Millerand, wife of the minister of war, has just accepted the presidency of a new society, the Blue Cross, organized on the model of the British Blue Cross, for the purpose of collecting from the battlefields and caring for wounded horses from which more service may be expected and which would otherwise die slowly of their wounds and of hunger where they have fallen. Eight Blue Cross ambulances are already operating at the front. They have been able to save many horses, a number of which have gone back to their regiments.

Measures Against Infectious Diseases in Algeria

Exceptional measures have just been decreed against epidemic and infectious diseases in Algeria. Not only physicians, but also heads of families and lodgers are bound to report to the mayor any case of infectious disease coming to their knowledge. The mayor is to report such cases to the local sanitary authorities.

The University of Aix Offers Hospitality to the Belgian Universities

At a meeting held at the Aix city hall, presided over by the mayor and university authorities, it was unanimously decided to make an official offer to the Belgian government to receive the Belgian universities, both professors and students, at the University of Aix. The city will defray the expenses of the students' lodging. The university will request that our minister of public construction permit the Belgians to receive instruction free and allow the University of Aix-Marseilles to confer French university degrees on the Belgian students.

Bureau of Chemical Products

A temporary bureau of chemical and pharmaceutical products has just been created to last during the war. Its function is to cooperate with our manufacturers with regard to production and distribution. It will investigate supplies, gather figures on our exact present capacity for production, develop production as much as possible to meet the needs of the civil population and, so far as possible, the needs of the allies. It will also attempt to establish in France the manufacture of products which hitherto have been monopolized by foreign countries. The bureau will be a division of the Department of Commerce, and its head will be M. Behal, professor at the Ecole supérieure de pharmacie de Paris and a member of the Académie de médecine.

Prohibition of Alcoholic Drinks

I mentioned in a previous letter (The Journal, Sept. 19, 1914, p. 1044), the prohibition of the sale of absinthe in drinking shops. This prohibition has been extended to apply to drinks similar to absinthe, that is, to bitters and all *apéritives* except those with a wine base. This measure applies to all France. Some military commanders have, in addition, taken such local measures as the closing of drinking-shops, the prohibition of the sale of alcohol in certain places, or the strict regulation of hours of closing. All these measures have already given good results with respect to the habits, behavior and health of the population. It is to be hoped that the new habits contracted during war may have an influence in suppressing the scourge of alcoholism.

The Soldiers' March

Dr. L. Manouvrier, professor at the Ecole d'anthropologie de Paris, at one of the last sessions of the Académie des sciences, read a paper on the grouping of marching soldiers, not according to their height but according to the length of the leg, measured from the great trochanter to the ground. When the soldiers with the shortest legs are put in front, the troop marches most regularly and with a minimum of fatigue.

Marriages

Robert Morton Wolfe, M.D., Port Carbon, Pa., to Miss Cora M. Bagenstose of Shoemakersville, Pa., at Philadelphia, October 3.

William Graves Phillips, M.D., Helena, Ky., to Miss Elizabeth Byram Ewan of Flemingsburg, Ky., October 20.

Alexander S. Waiss, M.D., San Francisco, to Miss Anna M. Wueck of Reading, Pa., at San Francisco, August 24.

Onnie Earl Stevenson, M.D., Labette, Kan., to Miss Nancy Wilmetta Belknap of Altamont, Kan., October 11.

Frank Beeby Conterman, M.D., Ilion, N. Y., to Miss Beatrice Thornton Buley of Syracuse, N. Y., October 15.

John Sullivan Clifford, M.D., Charlotte, N. C., to Miss Mary Agnes Keely, at Nashua, N. H., October 21.

John Adolph Greene, M.D., to Miss Huldah Elizabeth Pettengill, both of Rumford, Me., October 21.

Charles Walsh McQuillen, M.D., Cascade, Ia., to Miss Frances Bradley of Iowa City, Ia., October 19.

John Hudson Blauvelt, M.D., Beacon, N. Y., to Miss Mae Costello Furman of Nyack, N. Y., October 21.

John Harold Powers, M.D., Pueblo, Colo., to Miss Edith May Brooks of Wellington, Kan., October 20.

Edmund William Butler, M.D., San Francisco, to Miss Wilma Jacobs of Berkeley, Cal., October 19.

William Alvah Parks, M.D., to Miss Mary Alice Sell, both of Akron, Ohio, September 15.

Jacques J. Roth, M.D., New York City, to Miss Nellie A. Levy of Passaic, N. J., October 21.

Frank Anson Becker, M.D., to Miss Edna Refsum, both of New York City, October 21.

Walter Dent Wise, M.D., to Miss Agnes Bordon Whiting, both of Baltimore, October 20.

Oscar Lewis Zelle, M.D., to Miss Elizabeth Kane, both of Springfield, Ill., October 20.

Roy Newton Fuller, M.D., to Miss Lena Hesse, both of Tulare, Cal., October 21.

Charles Francis Yerger, M.D., to Miss Helen Zegar, both of Chicago, October 17.

Deaths

Edward Hodges, M.D. Long Island College Hospital, 1895; a Fellow of the American Medical Association and of the Association of Military Surgeons of the ates; assistant surgeon of the Forty-Seventh New nfantry, U. S. A., during the Spanish-American War service in Porto Rico; for several years captain and tant surgeon, N. G., N. Y., assigned to the Twenty-Third try; once president of the Long Island Medical Society; ng surgeon to the House of St. Giles the Cripple, Brook- nd associate visiting surgeon to Williamsburg, Bush- Swedish and Samaritan Hospital; died at his home in lyn, October 30, from pneumonia, aged 44.

h Smith Richards, M.D. Bellevue Hospital Medical 1875; a Fellow of the American Medical Association; director of the Dr. W. H. Groves Latter Day Hospital, and surgeon to the San Pedro, Los Angeles Lake Railroad, Salt Lake City; for many years geon to the Holy Cross Hospital, Salt Lake City; home, October 30, from Hodgkin's disease, aged 66.

Maximilian von Starkloff, M.D. University of ermany, 1854; surgeon of the Forty-Third Illinois fantry and medical director of the First Division, Corps during the Civil War; formerly pro- edic surgery in the Marion-Sims-Beaumont cine; for many years a practitioner of St. home in that city, October 31, aged 86.

M.D. Medical College of Ohio, Cincin- *of the Kentucky State Medical Associa-* the Civil War and past department and Army of the Republic, State of s a member of the state legislature ited States in China; died at his tober 23, aged 71.

John J. Castellanos, M.D. Tulane University, New Orleans, 1856; a member of the Louisiana State Medical Association, and second vice-president of the Orleans Parish Medical Society in 1892; *adjunct professor of surgery* and lecturer on surgery and later professor of surgical anatomy in the Charity Hospital Medical College, New Orleans; died at his home in that city, October 29.

Cyrus Jay Seltzer, M.D. University of Pennsylvania, Philadelphia, 1881; for twenty years *assistant surgeon at the Wills Eye Hospital*, Philadelphia; laryngologist to the Philadelphia Hospital and Philadelphia Polyclinic Hospital; for the last five years a resident of Lebanon, Pa.; died at his home in that city, October 23, from heart disease, aged 59.

John R. Colburn, M.D. Washington University, St. Louis, 1878; *a Fellow of the American Medical Association; president* of the Pacific Coast Railway Surgeons Association in 1907; for several years chief surgeon of the Salt Lake, San *Pedro and Los Angeles Railway*; died at his home in Los Angeles, October 27, from heart disease, aged 60.

Franklin Pierce Miller, M.D. New York University, New York City, 1876; visiting physician to the Bushwick Hospital and to the outpatient department of St. Mary's Hospital, Brooklyn; since his retirement in 1912, a resident of Tappen, N. Y.; died in the Long Island College Hospital, Brooklyn, October 17, aged 60.

Roland F. Blount, M.D. Central College of Physicians and Surgeons, Indianapolis, 1898; of Rushville, Ind.; a Fellow of the American Medical Association; died in a hospital in Indianapolis, August 28, from carcinoma of the pancreas, seventeen days after an operation on the gall-bladder, aged 40.

Frederick Joseph McNulty, M.D. Cooper Medical College, *San Francisco, 1896*; of Yreka; *a member of the Medical Society of the State of California*; physician and surgeon to the Siskiyou County Hospital; died at Oakland, Cal., while being taken to San Francisco for special treatment, October 21, aged 45.

Floyd Benton Parke, M.D. University of Buffalo, N. Y., 1879; a Fellow of the American Medical Association and *prominent as a dermatologist; health officer of Elmira township* and health commissioner of the city of Elmira; died at his home in Elmira, N. Y., October 9, from heart disease, aged 58.

James Sanford Denison, M.D. University of Tennessee, Nashville, 1904; a member of the Oklahoma State Medical Association and president of the McCurtain County Medical Society; *a physician in the United States Indian Service*; died at his home in Garvin, Okla., October 29, from malarial fever, aged 38.

William H. Bramblitt, M.D. New York University, New York City, 1857; a member of the Medical Society of Virginia; surgeon in the Confederate Army during the Civil War; died at his home in Pulaski, Va., October 30, from pneumonia following a fracture of the hip six days before, aged 85.

Franklin Fremont Finical, M.D. Starling Medical College, Columbus, Ohio, 1893; a member of the Ohio State Medical Association; *assistant surgeon of the Pennsylvania System* at Denison, Ohio, and a member of the Denison Board of Education; died at his home in that city, October 23, aged 51.

Daniel D. Neff, M.D. Bellevue Hospital Medical College, 1894; a member of the Syracuse Academy of Medicine; was found dead in his home in Syracuse, October 13, from the effects of poison, self-administered, it is believed, with suicidal intent while despondent on account of ill health, aged 45.

James Porter Brallier, M.D. *Medico-Chirurgical College* of Philadelphia, 1909; a Fellow of the American Medical Association; and a well-known young surgeon of Alexandria, Pa.; was crushed under an overturned automobile, October 18, near Hollidaysburg and instantly killed, aged 31.

Daniel Michael Sheedy, M.D. New York University, New York City, 1888; a member of the surgical staff of St. Francis' Hospital, *Poughkeepsie, N. Y.*; died suddenly at his home in that city, October 31, from heart disease, aged 49.

Warren H. Taylor, M.D. Detroit College of Medicine, 1896; a member of the Michigan State Medical Society and coroner of Genesee County; died at his home in Flint, Mich., October 29, from cerebral hemorrhage, aged 41.

Stanley Michael Piotrowski, M.D. Chicago College of Medicine and Surgery, 1914; died at his home in Chicago, September 18, from diabetes, aged 27.

Burr G. Carleton, M.D. New York Homeopathic Medical College, New York City, 1876; genito-urinary surgeon to the Metropolitan, Hahnemann and Flower hospitals, New York City; a specialist on diseases of the kidney; died at his home in New York City, October 29, from heart disease, aged 57.

Cyrus Cue Davis Shelburn, M.D. Hospital College of Medicine, Louisville, Ky., 1906; a member of the Kentucky State Medical Association; died at his home in Cunningham, Ky., October 25, from the effects of poison self-administered, it is believed, with suicidal intent, aged 40.

John Wesley Beckett, M.D. Howard University, Washington, D. C., 1905; a member of the Medical Society of the State of Pennsylvania; a colored practitioner and one of the city physicians of Pittsburgh; died in the West Penn Hospital in that city, October 20, aged 35.

John Joseph Cassidy, M.D. University of Toronto, Ont., 1869; for sixteen years editor of the *Canadian Journal of Medicine and Surgery* and formerly president of the Board of Health of Toronto; died at his home in that city, August 1, from heart disease, aged 71.

Samuel Butler Grimes, M.D. University of Maryland, Baltimore, 1897; of Roland Park, Md.; died at the home of his father in Baltimore, October 25, from the effects of a gunshot wound of the head, self-inflicted it is believed with suicidal intent, aged 39.

Crowell Clarinton Hall, M.D. Dartmouth Medical School, Hanover, N. H., 1876; a member of the Maine Medical Association and one of the most prominent and wealthy citizens of Piscataquis County; died at his home in Dover, Maine, October 19, aged 60.

Frank Merril Vebber, M.D. Eclectic Medical College of the City of New York, 1884; town health officer of Clayton, N. Y.; coroner of Jefferson County in 1885 and 1888; died in the Watertown, N. Y., City Hospital, October 20, from diabetes, aged 58.

Phillip E. Parker, M.D. Tulane University, New Orleans, 1885; a Fellow of the American Medical Association; of Bay City, Tex.; was accidentally shot by a companion while shooting October 15 and died in the Jones Hospital, October 16, aged 55.

Robert W. Earll, M.D. Rush Medical College, 1853; formerly superintendent of the Columbus, Wis., Hospital, and for many years a practitioner of Milwaukee; died at the home of his daughter in Denver, October 26, from pneumonia, aged 91.

Walter Samuel Baker, M.D. New York Homeopathic Medical College, New York City, 1863; for more than half a century a practitioner of Newark, N. J.; died at his home in that city, October 26, from cerebral hemorrhage, aged 73.

Levi Houghton Kimball, M.D. Boston University, 1877; formerly of Bath, Maine, and for two terms a member of the city council; died at his home in Roxbury, Boston, October 21, aged 61.

Thomas J. Boyson, M.D. Royal University of Copenhagen, Denmark, 1869; of Plymouth, Cal.; died in the German Hospital, San Francisco, October 2, from cerebral hemorrhage, aged 69.

John Franklin Clark, M.D. University of Alabama, Mobile, 1909; a Fellow of the American Medical Association; died at his home in Paint Rock, Ala., September 22, aged 34.

John Robinson Gamble, M.D. Bellevue Hospital Medical College, 1866; a retired practitioner of Knox County, Ohio; died at his home near Mount Vernon, July 19, aged 77.

David C. Harmison, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1878; a veteran of the Civil War; died at his home in Havana, Ill., October 19, aged 69.

Charles G. Kuhlman, M.D. Rush Medical College, 1889; of San Francisco; a member of the Medical Society of the State of California; died in San Francisco, October 8.

John Fullerton Hicks, M.D. University of Michigan, Ann Arbor, 1865; died at his home in Menominee, Mich., October 17, from cerebral hemorrhage, aged 76.

J. Jackson Crider (license, Iowa, 1886) an itinerant practitioner; died at his home in Columbus Junction, Ia., October 12, from cerebral hemorrhage; aged 82.

John W. Jones, M.D. Eclectic Medical Institute, Cincinnati, 1868; of Milton, Wis.; died at his home in that place, October 21, aged 75.

Edwin A. Gaviller, M.D. McGill University, Montreal, 1873; died at his home in Hamilton, Ont., August 8, aged 74.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

ARTICLES REFUSED RECOGNITION

Reports of the Council on Pharmacy and Chemistry

For the benefit of the medical profession and the encouragement of honest manufacturers, the Council on Pharmacy and Chemistry, when first organized, decided to publish a book which should contain authoritative information about medicinal preparations found to merit the consideration of physicians. This book, New and Nonofficial Remedies (N. N. R.) is republished annually, so that each edition contains descriptions of all the proprietary and nonofficial remedies which, up to the date of issue, the Council has found worthy of recognition. During each year descriptions of additional preparations appear in The Journal, are later issued in supplements to N. N. R., and finally are incorporated in the next edition of the book.

In addition to N. N. R., with its descriptions of medicinal articles found "acceptable," the Council has authorized for publication from time to time reports dealing with proprietary articles or with certain phases of the proprietary medicine business. These reports have been issued annually in book form, those deemed of interest to the general medical practitioner being previously published in The Journal. Reports which were of direct interest only to a few have been published in the annual volume only.

While, in its Reports, the Council has published the reasons which led to the rejection of some of the articles investigated, by far the greater portion of the Council's investigations have not been published for two reasons. First, it was thought that many of the products found ineligible did not justify reports because they were of interest to few physicians; and, second, it was desirable that the manufacturers should be given an opportunity to modify or improve the preparations found ineligible and thus make them acceptable to inclusion in N. N. R.; therefore, publication of reports dealing with rejected articles was postponed so far as possible. The Council having been in existence for nearly ten years, manufacturers have had ample time to adapt themselves to new conditions, and one of the reasons for delayed publicity no longer holds good. So far as the other reason is concerned, inquiries which come to the Council and to The Journal indicate that physicians do, for various reasons, seek information in regard to many proprietary products regarding which no report has been published. The Council, therefore, has decided to make public, even when no detailed reports are prepared, a brief outline of the reasons which led to the rejection of articles. In case consideration of such products was requested by their manufacturer or their distributing agents, these abstracts are not published until they have been submitted to the interested parties. When the Council takes up the consideration of an article on its own initiative, the abstract of such consideration naturally is published without consideration of the manufacturer. Included with these abstracts also will be brief abstracts of Council reports which have been prepared only for publication in the annual reports. The Council has authorized the publication of the first instalment of abstracts, which appears below.

Agar-lac

Agar-lac, said to be the product of "Agar-lac, Inc.," is sold by E. Fougera and Company, New York. The following "formula" for Agar-lac is published:

"Agar-Agar with Lactic Ferments.............. Grs. 4½
Phenolphthalein .... Grs. ½"

Regarding the "lactic ferment," the identity of which is not declared by the manufacturer and for the viability of which no precautions appear to be taken, the Council's expert on lactic acid ferments reported that *Bacillus bulgaricus* was present in small numbers only and that there were at least two other bacteria present, one of which is a gas-former of the *Bacillus coli* type.

The Council found that the amount of agar-agar in Agar-lac and the identity of the "lactic ferment" are not declared; that the name "Agar-lac" is blown in the glass and that the method of its exploitation will lead laymen to use it to their detriment; that the claims that it "facilitates assimilation of proteids" and that it is of value as an aid to "gastro-intestinal digestion" give a false value to the mixture and that the claims emphasize the action of agar-agar when from the composition it is evident that the phenolphthalein action will predominate; that the name does not indicate its predominating constituent, phenolphthalein, and that the use of a ready-made combination of cathartic drugs, such as agar-agar and phenolphthalein with lactic acid ferments, is unscientific.

Aseptikons

Aseptikons are vaginal suppositories sold by the Chinosol Co. of New York. Each suppository is said to contain:

Ac. Salicicylici	2 grs.
Ac. Borici	10 grs.
Quin. purae (Alkal.)	1 gr.
Chinosol	2 grs.
But. Cacao	60 grs.

The following claims appear in advertisements:

> "These suppositories are indicated in cervicitis, leucorrhea, specific and non-specific vulvo-vaginitis and in all cases where complete vaginal antisepsis is desired."
>
> "*Non Toxic, Non Irritating, No Damage to Membranes. Yet a More Powerful Antiseptic than Bichloride.*"

The Council decided that the foregoing claims in the absence of evidence must be held exaggerated and likely to mislead, and also that the claim "Stronger than Bichloride" which appears on the box is misleading.

The position of the Council is that "In the case of pharmaceutical preparations or mixtures the trade name must be so framed as to indicate the most potent ingredients." The name Aseptikons does not give any indication of the ingredients of the product.

The Council holds that "The combination of two or more remedies in a mixture must be considered contrary to scientific medicine unless a distinct reason exists for such combination." No evidence has been submitted to establish the value of the combination in Aseptikons.

On the basis of the evidence submitted the Council voted that Aseptikons be refused recognition because unwarranted and misleading therapeutic claims are made because the name does not indicate its potent constituents, and because the combination of two or more remedies in a mixture is considered contrary to scientific medicine unless a distinct reason exists for such combination.

Bacillicide

Bacillicide, sold by the Prophytol Products Company, Richmond, Va., is an antiseptic solution of the Glyco-Thymoline type. Vague, indefinite and misleading statements are made in regard to its composition and method of preparation.

The Council voted that Bacillicide was unacceptable because only a non-quantitative and therefore meaningless formula was published; because vague and unsubstantiated statements were made as to its method of preparation (removal of irritating action of formaldehyde); because exaggerated claims as to its therapeutic action were made; because its name did not indicate the potent ingredients of the pharmaceutical mixture but suggested its use without consideration of the composition, and because the use of an indefinite complex preparation such as Bacillicide is represented to be, is contrary to the best interests of the public.

Iron Solution for Intravenous Therapy—Perkins and Ross

Iron Solution for Intravenous Therapy, Perkins and Ross, manufactured by Perkins and Ross, Colorado Springs, Colo., is said to be an aqueous solution containing soluble iron phosphate, sodium chloride and "calcium creosote." Its use by intravenous injection is recommended as a "chalybeate, emmenagogue and tonic" and in "all conditions in which iron is indicated." The advertising circular overemphasizes the use of intravenous medication and minimizes its drawbacks and dangers.

The composition of "calcium creosote" was not furnished and it was acknowledged that only a part of the "calcium creosote" enters into the solution. As the intravenous administration of a drug like iron, which must be continued for long periods, cannot be considered the method of choice, as the composition of the solution is such that changes may occur on standing, etc., which would make the preparation dangerous, and as the method of marketing the solution does not insure its sterility, further increasing the danger of its use, the product was rejected.

(To be continued)

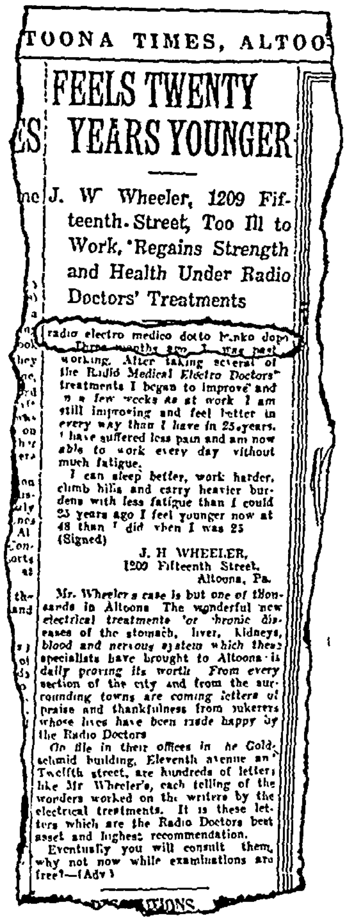
THE RADIO MEDICAL ELECTRO DOCTORS

A Printer Inadvertently Expresses an Opinion on These Doctors

In preparing manuscript for publication, it is not unusual to insert what are known as "catch lines" for the purpose of aiding the "make-up man" in preparing the matter according to the author's ideas. Such "catch lines," of course, are deleted by the proofreader before the material finally appears in its finished form. Occasionally, however, these lines are overlooked, and the reader is given a peep behind the scenes of the printing office.

Itinerant quacks have certain stock advertisements which are interspersed with testimonials—genuine or faked. The testimonials, being a fluctuating quantity, are usually sent separately from the main advertisement.

The Radio Medical Doctors is the name assumed by some quacks who have recently been operating in Altoona, Pa. In common with their kind, they publish advertisements in local newspapers. We reproduce in miniature one advertisement that appeared in the Altoona *Times* Oct. 1, 1914. It consists of the usual extravagant statements found in such advertisements, together with a testimonial from a Mr. Wheeler. The testimonial had evidently been sent to the printers at a different time from the body of the advertisement. That the type-setter might know just where this testimonial was to be used, he headed it with a "catch line." This "catch line" we have marked in the miniature reproduction, and that it may be more easily read, have reproduced slightly enlarged thus:



TOONA TIMES, ALTOO

FEELS TWENTY YEARS YOUNGER

J. W Wheeler, 1209 Fifteenth Street, Too Ill to Work, Regains Strength and Health Under Radio Doctors' Treatments

radio electro medico docto bunko dope

Three months ago I was past working. After taking several of the Radio Medical Electro Doctors' treatments I began to improve and in a few weeks was at work. I am still improving and feel better in every way than I have in 25 years. I have suffered less pain and am now able to work every day without much fatigue.

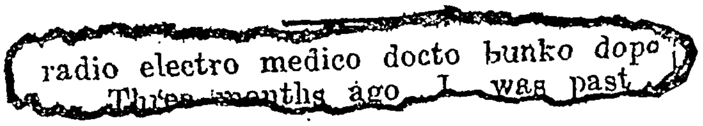
I can sleep better, work harder, climb hills and carry heavier burdens with less fatigue than I could 25 years ago I feel younger now at 48 than I did when I was 25 (Signed)

J. H WHEELER,
1209 Fifteenth Street,
Altoona, Pa.

Mr. Wheeler's case is but one of thousands in Altoona The wonderful new electrical treatments for chronic diseases of the stomach, liver, kidneys, blood and nervous system which these specialists have brought to Altoona is daily proving its worth From every section of the city and from the surrounding towns are coming letters of praise and thankfulness from sufferers whose lives have been made happy by the Radio Doctors

On file in their offices in the Goldschmid building, Eleventh avenue and Twelfth street, are hundreds of letters like Mr Wheeler's, each telling of the wonders worked on the writers by the electrical treatments. It is these letters which are the Radio Doctors best asset and highest recommendation.

Eventually you will consult them, why not now while examinations are free?—(Adv)



radio electro medico docto bunko dope
Three months ago I was past

The average newspaper man, whether he works in the composing room or on the editorial staff, is usually no fool. The printer who headed the Radio Medical Electro Doctors' testimonial as "bunco dope" was "wise." His classification cannot be improved on.

MAIGNEN ANTISEPTIC POWDER

Report of the Council on Pharmacy and Chemistry

The report which appears below was submitted by a referee and after adoption by the Council was sent to the manufacturer for comment, in accordance with the Council's regular procedure in such cases. The manufacturer's comments were transmitted to a second referee, who reported that after a careful consideration of the manufacturer's reply he saw no valid reason for a modification of the report. The referee also reported that a visit to the Maignen Institute further served to convince him of the viciousness of the treatment as given and that the records made by the persons in the employ of the institute were too inadequate to serve as clinical evidence. On the referee's recommendation, the report as originally adopted was reendorsed by the Council and authorized for publication. W. A. Puckner, Secretary.

Maignen Antiseptic Powder is marketed by the "Maignen Institute for the Study of Bacterial Diseases," Philadelphia. It is claimed to be a mixture of calcium hydroxid, sodium carbonate, aluminum sulphate and boric acid, but no statement as to the amount of the several constituents is furnished. Its action depends on the sodium hydroxid which is formed when the powder is treated with water, 1 Gm. of the powder as now submitted to the Council yielding 0.32 Gm. of sodium hydroxid (NaOH) and a specimen obtained a year ago yielding 0.28 Gm. Its promiscuous use is recommended both to physicians and to the public with claims which are extravagant, preposterous and even dangerous.

A pamphlet, clearly intended for the laity, entitled "What Is Catarrh?" gives direction for the "sterilization" of the nose, throat, stomach, lungs, eyes, gums, mouth and the genito-urinary tract. The following, taken from this pamphlet, illustrates the absurdity of the claims made for Maignen Antiseptic Powder:

> "STERILIZATION OF THE STOMACH
>
> "Take of the Maignen Antiseptic Powder half the quantity raised on a dime, scant.
>
> "Add to a tumbler of water, preferably warm, and stir.
>
> "Drink slowly.
>
> "This is what may happen:
>
> "1). Belching may be the first indication of the sterilization of the stomach.
>
> "2). The excess of acidity is corrected.
>
> "3). The fermentation is stopped.
>
> "4). The sterilization extends to the Intestinal Tract.
>
> "5). The bowels are regulated without purgation.
>
> "6). The whole metabolic process is improved.
>
> "When and how often to drink the antiseptic solution.
>
> "a). For Indigestion, whenever distressed, before or after meals.
>

>
> "c). For Gastro-Intestinal troubles, such as Typhoid Fever, Dysentery and Cholera, which are the most serious forms of catarrhal inflammation, take half a tumbler or a whole tumbler of hot water with half the quantity of Powder raised on a dime every hour, and between times a glass of generous [sic] wine.
>
> "Remarks
>
> "The sterilization recommended here is a plain disinfecting process which does not interfere with medical treatment. It is, on the contrary, of great assistance to it.
>
> "It has been found very effective in breaking up the cigarette habit. It does away with the craving by removing the morbid irritation of the mucous membrane."

Eighty-eight disorders are listed in a pamphlet entitled "Antiseptic Therapeutics" all of which are reported as having been treated with success. The dangerous character of the Maignen "sterilization" propaganda is illustrated by a pamphlet "First Aid to Baby-Sick" and by the recommendation on the trade package:

> "To prevent Blood Poisoning, Lockjaw, Hydrophobia and Infectious Diseases."

The legend on the trade package and the advertising matter contained in it are likely to lead the public to place dependence on a weak sodium hydroxid solution as a means of preventing blood-poison, lockjaw, hydrophobia and infectious diseases. The pamphlet "First Aid to Baby-Sick" recommends its use in sore eyes, teething and sore mouth, sore throat, running ears, running nose, sore chest, summer complaint, skin troubles and infection after vaccination; if any trust is put in these claims, they are bound to lead to the sacrifice of many infants through neglect of proper treatment.

Patent No. 1,086,339 has been granted on this powder to P. J. A. Maignen of Philadelphia by the U. S. patent office on the following specification of claim made in the application:

> "1. A process for destroying microorganisms on living tissue, without injuring the latter . . . whereby the growth of such organisms is inhibited and their substance dissolved without deleterious effect upon contiguous healthy tissue."

With brazen assurance this grant has been twisted by the unscrupulous promoters into a government endorsement of the preparation. It, of course, means nothing of the sort, as, no doubt, in accordance with legal routine the patent was granted without any investigation by the patent office to determine the effectiveness of the powder for the purpose claimed.

In view of the dangerous, unwarranted and absurd claims made for Maignen Antiseptic Powder the referee recommends that it be refused recognition, and that the Council declare its agreement with views expressed in the article "Maignen Pulv." published in The Journal, Feb. 15, 1913, p. 537, particularly the following:

> "The germicidal powers of strong alkalies have long been known, but the inconvenience of their application to tissues and mucous membranes has prevented their use. That they will be of service when sufficiently diluted not to irritate the tissues is improbable, for the antiseptic power of such solution is slight and the disinfectant value practically nil."

Because the Maignen Institute has twisted the granting of U. S. patent No. 1,086,339 into a quasi-endorsement of the claims made for Maignen Antiseptic Powder it is recommended that a copy of this report be sent to the Commissioner of Patents as a protest against the present law, which authorizes the granting of patents on unproved and improbable medical claims.

Unauthorized Insertion of Advertisement

To the Editor:—I notice the regular Kenilworth Sanitarium advertisement displayed in the October number of *American Medicine*, and I would thank you to put this note in The Journal of the American Medical Association, in order that the medical profession may be informed that the insertion of said advertisement was entirely unauthorized.

Sanger Brown, M.D., Kenilworth, Ill.
Chief of Medical Staff, Kenilworth Sanitarium.

[Comment.—The foregoing may explain how it sometimes happens that clean, ethical advertisements appear in publications whose principal income is derived from nostrum and fake advertisements.—Ed.]

The Metchnikoff Theory

To the Editor:—The theory, so ably supported by Metchnikoff, which ascribes to the leukocytes the function of picking up and destroying bacteria which find their way into the blood or tissues (phagocytosis) is now generally accepted as having been demonstrated by observation and experimental evidence.

I have no desire to detract from the credit due to Metchnikoff in connection with this theory, but in justice to myself desire to call attention to the fact that this theory was suggested by me several years before the publication of Metchnikoff's first paper on the subject. In support of this statement, I quote from my book entitled "Bacteria," published in 1884 (William Wood & Co., New York), pp. 250 and 251:

> "If we add a small quantity of culture-fluid containing the bacteria of putrefaction to the blood of an animal, withdrawn from the circulation into a proper receptacle, and maintained in a culture-oven at blood-heat, we will find that these bacteria multiply abundantly, and evidence of putrefactive decomposition will soon be perceived. But, if we inject a like quantity of the culture-fluid with its contained bacteria into the circulation of a living animal, not only does no increase and no putrefactive change occur, but the bacteria introduced quickly disappear, and at the end of an hour or two the most careful microscopical examination will not reveal the presence of a single bacterium. This difference we ascribe to the vital properties of the fluid as contained in the vessels of a living animal; and it seems probable that the little masses of protoplasm known as white blood corpuscles are the essential histological elements of the fluid, so far as any manifestation of vitality is concerned.

"*The writer has elsewhere suggested that the disappearance of the bacteria from the circulation, in the experiment above referred to, may be effected by the white corpuscles,* which, it is well known, pick up, after the manner of amoebae, any particles, organic or inorganic, which come in their way. And it requires no great stretch of credulity to believe that they may, like an amoeba, digest and assimilate the protoplasm of the captured bacterium, thus putting an end to the possibility of its doing any harm.

"In the case of a pathogenic organism we may imagine that, when captured in this way, it may share a like fate if the captor is not paralyzed by some potent poison evolved by it, or overwhelmed by its superior vigor and rapid multiplication. In the latter event, the active career of our conservative white corpuscle would be quickly terminated, and its protoplasm would serve as food for the enemy. It is evident that in a contest of this kind the balance of power would depend on circumstances relating to the INHERITED vital characteristics of the invading parasite and of the invaded leukocyte."

It seems to me that the theory of phagocytosis is very clearly stated in the foregoing quotation, although the term "phagocyte" had not yet been suggested.

The book from which the quotation is made was published in the spring of 1884, but it was written in 1883 and the preface, written last, is dated Aug. 15, 1883. The statement that "the writer has elsewhere suggested that the disappearance of the bacteria from the circulation in the experiment above referred to may be effected by the white corpuscles" is supported by the following quotation from a paper read at the Cincinnati meeting of the American Association for the Advancement of Science, Aug. 18, 1881:

"It has occurred to me that possibly the white corpuscles may have the office of picking up and digesting bacterial organisms which by any means find their way into the blood. The propensity exhibited by the leukocytes for picking up inorganic granules is well known, and that they may be able not only to pick up but to assimilate, and so dispose of, bacteria which come in their way does not seem to me very improbable in view of the fact that amoebae, which they resemble so closely, feed on bacteria and similar organisms" (*Tr. A. A. A. S.* for 1881, p. 175).

The paper from which this quotation is made is entitled "A Contribution to the Study of the Bacterial Organisms Commonly Found on Exposed Mucous Surfaces and in the Alimentary Canal of Healthy Individuals. Illustrated by Photo-Micrographs. By George M. Sternberg, Surgeon U. S. Army, late 'Fellow by Courtesy' of the Johns Hopkins University. With Plates XI, XII and XIII."

The first record I can find of Metchnikoff's announcement of the theory of phagocytosis is in his paper in *Virchows Archiv,* 1884, xcvi, 177, "Ueber eine Sprosspilzkrankheit der Daphnien."

George M. Sternberg, M.D., Washington, D. C.

"Flying Clinics" in the Medical Treatment of Rural Schoolchildren.—Dr. A. E. Williams describes in the *Journal of State Medicine* for October some of the measures employed in the medical treatment of schoolchildren in Great Britain. In thinly populated rural districts facilities for remedying many defects found among the children are lacking. Although the children of the rural districts are, as a rule, healthier and stronger than those in more thickly populated districts, it became necessary to devise some special measures for treating defective vision, dental caries, etc. For this purpose, "flying clinics" were established. For the flying eye clinic, a portable apparatus was devised, consisting of a small tent of dark material for a dark room, an ophthalmic lamp and a case of trial lenses. For dental defects, both flying clinics, working from school to school throughout a county, and clinics at a fixed center to which all the children in the given county were sent, were employed. Dr. Williams says it is now proved that flying clinics are both practical and useful, the cost being not great. He believes that the time is not far distant when these clinics will be looked on as an essential feature in every scheme of medical inspection.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

THE PRICE OF RADIUM ACTIVATORS

To the Editor:—The treatment of disease by radium emanations is being urged on the medical profession by interested purveyors of apparatus for producing these emanations. There is a certain mystery with reference to radium which, combined with its high price, leads the physician readily to accept the prices charged for these activators. Thus, one of the most widely advertised activators is priced at $200 for an apparatus which will produce 2,500 Mache units per day in ½ liter of water. Another firm advertises a similar apparatus at a price of $165. Still another firm claims to produce an apparatus of equal capacity for $15.

Being interested in this subject, I wrote to several companies asking prices and particularly the amount of radium which is necessary to produce this quantity of emanation. To the first firm I wrote as follows:

"Please quote me the price of a — — — activator capable of furnishing 2,500 Mache units per day. Will you kindly indicate to me the approximate amount of radium that is necessary to produce this strength of radium emanation?"

With reference to the amount of radium necessary, the reply of this firm is somewhat evasive:

"In answer to your question as to the approximate amount of radium required to produce a desired strength of emanation, we beg to reply that this depends entirely upon which salt of radium you use, its concentration and how you use it. Its full emanation is available when a soluble salt, as bromide or a chloride is dissolved in water, but this is only temporary, as its strong affinity for other salts soon causes it to precipitate, even attacking the silica of the glass; the emanation is then greatly reduced—in instances we have known it to fall within 2.5 per cent. of its original amount. If an insoluble salt like the sulphate or the carbonate be used, you can generally obtain from 5 to 8 and sometimes even 10 per cent. of its available emanation. Unless you are thoroughly familiar with radium, we would not advise you to attempt constructing your own apparatus, because in the end you would undoubtedly lose a considerable proportion of your radium, and the result would be much more expensive than if you purchased an activator at the start."

Of course, it is well known that the different radium salts differ in their radium activity, but it would have been no great task for the firm to indicate the amount of some one salt or of radium element.

To the second company I wrote as follows:

"Do you furnish an activator for producing radium emanations? If so, please quote me the price of an apparatus capable of producing a solution containing 2,500 Mache units per day. Would you kindly tell me the approximate amount of radium necessary for the production of a water containing 2,500 Mache units per day?"

In reply to this query, I received the following letter:

"In answer to your inquiry in your letter of September 25, we are obliged to advise that we cannot supply an apparatus for the production of so small an amount of radium emanation as 2,500 Mache units per day. The amount of radium necessary for the production of a water containing 2,500 Mache units per day would be 0.01 mg. of radium element."

The third firm advertises an apparatus at the low price of $15, but says in its letter:

"The price of our No. — — — is $25. This we guarantee to generate 2,700 Mache units. This guaranty is based on a generating capacity of from 500 to 1,000 Mache units more than the rating. The reason for this is that the emanation is three times as soluble in air as it is in water, and in spite of careful handling, a certain amount of the emanation will be lost."

In view of these varying prices, it is pertinent to ask, What is the reason for this enormous excess charged beyond the value of the radium contained? One one-hundredth mg. of radium element is worth approximately $1.25. If this is the value of the radium contained in the apparatus, is it possible that bottles and containers are worth from $164 to $199? A similar disparity between charges and value appears in the price for rental of these pieces of apparatus. Thus, the apparatus costing $200 rents for $80 for a period of six months. Is it possible that the credit of physicians is so poor that they must pay such enormous prices? Even the cheap apparatus costing $15 is rented for $22.50 for a period of six months.

I would be much interested in any comments which you may see fit to make on this situation.

J. H. S.

Answer.—In reply to the first question, regarding the amount of radium necessary to produce 2,500 Mache units of emanation daily, it may be said that the total amount of emanation from 1 microgram (that is one millionth of a gram) of radium (element) will correspond to 2,700 Mache units. The total amount of emanation produced by a given amount of radium is that which is obtained from material that has been kept in a sealed vessel for six weeks or more. If all emanation is removed from a sample of radium at the start, then at the end of twenty-four hours only about one-sixth of the maximum amount of emanation will have accumulated. If all of the emanation produced were effective, then it would require 6 micrograms of radium to yield 2,700

Mache units in twenty-four hours. At $120 a milligram this amount of radium would be worth 72 cents.

The answer to the second question is in fair agreement with the foregoing statement. It is there stated that 0.01 mg. (10 micrograms) of radium element will produce 2,500 Mache units per day. Doubtless the writer of that statement made allowance for some loss, as would be inevitable in the actual therapeutic use of radium. Actually 10 micrograms of radium would produce emanation corresponding to 2,500 Mache units in about fourteen hours; or in twenty-four hours with a 58 per cent. efficiency.

When it comes to the practical utilization of the emanation in the preparation of drinking water the statements in reply to the first question are in the main correct. A chemist familiar with the manipulation of radio-active substance could by use of a soluble radium salt get each day practically the whole of the emanation produced and bring it into solution in the water intended for drinking. But such work requires technical skill in manipulation; in the first place to avoid loss of the emanation and secondly to prevent ultimate loss of the valuable radium or its spontaneous conversion into an insoluble form as pointed out in the answer to the first question.

The practicing physician, or the patient using the active water, is not in general skilled in the handling of radium or its emanation, and so requires an apparatus with which he "pushes the button, and the machine does the rest." In the "activators" on the market the radium is practically always in the form of an insoluble salt, probably sulphate or carbonate. In this form only a small percentage of the emanation is given off. Suppose, however, that only 5 per cent. is available, as this is the lowest figure given in the answer to the first question: then to produce 2,500 Mache units daily with 5 per cent. efficiency would require twenty times as much radium as if all the emanation were available, namely, 120 micrograms (0.12 mg.), worth $14.40.

In regard to the third question, it would seem that it would be possible to supply an activator which would give 2,500 Mache units daily at the price stated, $25, and still leave a reasonable margin of profit.

ARTICLES ON INTRASPINAL INJECTIONS OF SALVARSAN IN PARESIS AND LOCOMOTOR ATAXIA

To the Editor:—Please inform me if any extensive work is being carried on with intraspinal injections of salvarsan in cases of paresis and locomotor ataxia. Who is doing this work? Can a detailed statement or a summary of it be obtained?

A. E. Conter, M.D., Chattahoochee, Fla.

Answer.—The following is a list of references to the work on this subject:

Arkansas May Report

Dr. W. S. Stewart, secretary of the State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock, May 12-13, 1914. The total number of subjects examined in was 12; total number of questions asked, 120; percentage required to pass, 75. The total number of candidates examined was 61, of whom 51 passed and 10 failed. The following colleges were represented:

University of Tennessee	(1914)	63.7

The following questions were asked:

ANATOMY

1. Name the bones of the upper extremity. 2. Describe the scapula. 3. Give the boundaries and contents of the axilla. 4. Give the origin, relations and branches of the femoral artery. 5. Describe the duodenum, giving nerve and blood supply. 6. Name the structures composing the larynx, with nerve and blood supply. 7. Give the origin, course and termination of thoracic duct. 8. Give the origin, course and distribution of the musculospiral nerve. 9. Describe the fourth ventricle. 10. Name the structures divided in an amputation at knee-joint.

PHYSIOLOGY

1. Give the origin and significance of urea. 2. What general conditions or factors influence blood-pressure and blood-velocity? 3. Describe and discuss hunger and thirst. 4. Name the veins which form the portal vein, and give its function. 5. Give the function of the lymphatic system. 6. Give the function and location of the gall-bladder and its connection with other organs. 7. Define osmosis, endosmosis and exosmosis. 8. Name and describe the salivary glands. 9. What digestive disturbances follow the removal of the pancreas? 10. How do the products of digestion find their way into the blood?

CHEMISTRY

1. Name seven elements, giving symbol, valence and atomic weight. 2. How is oxygen prepared for commercial use? 3. Define organic, inorganic and physiologic chemistry. 4. Give chemical name and formula of sugar of lead; Epsom salts; tartar emetic. 5. What are the chemical changes if you mix calomel and lime-water? 6. Give Heller's test for albumin and the bismuth test for sugar in urine. 7. Give test for blood in urine. 8. What are proteins and from what are they derived? 9. What is lunar caustic? Dose? Antidote? 10. What is salol and when administered what chemical changes take place?

HYGIENE

1. Define hygiene. 2. Describe the physiologic action of alcohol. 3. Describe the preparation of patient, surgeon, instrument and surroundings for a surgical operation. 4. What is antitetanic serum? Give its use. 5. Give an effective method for controlling an epidemic of diphtheria. 6. What are the most important factors in preserving health, and how best observed and applied? 7. Name some of the conditions that predispose to or cause disease. 8. State the value of disinfection

and isolation in contagious diseases and the disinfectant employed. 9. How does hookworm enter the human system, and what measures should be taken to prevent it? 10. What would be your instruction to prevent the spread of typhoid fever?

MATERIA MEDICA

1. Define an expectorant. (*b*) Into what classes are expectorants divided? (*c*) Give an example of a nauseating expectorant. 2. Where does the belladonna plant grow? (*b*) What is its physiologic action? (*c*) What is its active principle? 3. What is a vascular contractor? (*b*) Give an example. 4. How much morphin is there in 1 ounce of powdered opium U. S. P.? (*b*) How much opium is there in 1 ounce of tincture of opium? 5. Define a solvent and an excipient. Give an example of each. 6. Give dosage of the following drugs: strychnin sulphate; hydrargyri chloridum mite; liquor poatssi arsenitis; hydrargyri iodid rubrum; ammonium chlorid; ferri sulphate; acetanilid; sodium salicylate; F. E. nucis vomica; atropin sulphate; ipecacuanha; magnesia sulphate. 7. Criticize the following prescriptions:

(*a*) F. E. Nucis Vomica oz. I.
Aquae q. s. ad oz. IV.
M. Sig. Tablespoonful t. i. d.—p. c.
(*b*) Tinct. Digitalis dr. ss.
Spts. Aetheris Nitrosi dr. III.
Liq. Ammon. Acetat. oz. ss.
Aquae q. s. ad oz. VI.
M. S. One ounce every three (3) hours.
(*c*) Tr. Ferric Chlorid dr. ss.
Tr. Iodine dr. ss.
Tannic acid grs. xx.
Glycerine q. s. ad oz. IV.
M. S. Swab throat.

8. Give properties and physiologic action of potassium permanganate. 9. Give physiologic action of potassium bromid. 10. How does acetanilid reduce an elevated temperature?

THERAPEUTICS

1. Name two conditions in which you would use thymol and state how you would use it. 2. What is especially indicated in treating scrofulosis with glandular enlargement? 3. In collapse of pneumonia, name the most efficient remedy and mode of administration. 4. Name six routes by which we may introduce remedies into the circulation. 5. How would you combat opium poisoning? 6. Give therapeutic uses of salicylic acid. 7. How may we administer ipecac in large doses without causing nausea? 8. Name three official preparations of mercury and give therapeutic uses of each. 9. Describe the technic in the administration of diphtheritic antitoxin. How does it combat the disease? 10. What class of patients is it that does not bear chloral hydrate well?

SURGERY

1. Describe ligation of the radial artery in the upper third. 2. Give symptoms, diagnosis and treatment of tuberculosis of the kidney. 3. What are the symptoms of air embolism? Give treatment. In what regions are surgical operations most liable to be followed by this condition? 4. Name three forms of bowel obstruction. Give symptoms that are common to each. Outline a surgical operation that may be required in any one form selected. 5. Give differential diagnosis of luxation of the hip and fracture of the surgical neck of the femur. Give methods of management of each. 6. Describe in detail an amputation of a finger at the metacarpophalangeal joint. 7. Define hernia. Describe oblique inguinal hernia; give symptoms of strangulation and treatment. How measure and fit a truss in inguinal hernia? 8. What is shock? Give symptoms. Give the treatment and the precautions that may be taken for its prevention. 9. Define necrosis and give the causes and surgical treatment. 10. Name varieties of fistula in ano and give treatment. Describe an operation for removal of hemorrhoids. Give symptoms and treatment of ischiorectal abscess.

OBSTETRICS

1. Describe how you would conduct a normal labor. Give in detail asepsis in conection therewith. Also what attention would you give the child if Neisser infection is suspected with the mother? 2. Define abortion and miscarriage. State how you would manage a case of incomplete abortion. Also state some morbid conditions of mother that is a frequent cause of either occurring. 3. What are the more frequent morbid conditions of the breasts which occur in puerperium? Give prophylaxis and treatment for same. 4. Give the mechanism of normal labor in R. O. A. position. 5. State how you would apply forceps in R. O. P. position, and what emergencies and complications should you be prepared for at such a delivery? 6. Give the varieties of version, and give in detail method of doing same in any variety you may select. 7. What is accidental hemorrhage occurring in gestation? Give causes, varieties and treatment. 8. How would you manage a case of retained placenta associated with profuse hemorrhage? 9. Describe some of the more frequent etiologic factors in puerperal infection. 10. What is asphyxia neonatorum? Give causes and treatment. Describe Sylvester's method of artificial respiration.

PATHOLOGY

1. Explain the development of pus cells. 2. What general pathologic lesions characterize chronic alcoholism? 3. Describe the pathogenesis of gall-stones and the physical and chemical characteristics of one variety. 4. What is cretinism and with what is it associated? 5. Describe in detail the pathogenesis of pellagra. 6. What pathologic changes may cicatrices undergo? 7. What valve is most commonly involved in endocarditis? (*b*) What are the structural types of endocarditis and the common micro-organisms that produce these lesions? 8. What conditions may cause dropsical effusions in the abdomen and in the lower extremity? 9. What laboratory methods may be of service in the diagnosis of cancer of the stomach? 10. Name the varieties of urinary renal casts, describe the characteristics of each and state what forms of renal disease they are a part.

GYNECOLOGY

[illegible] What is pruritus vulvae? Give causes and treatment. 2. Name [illegible]erent forms of vaginitis, giving etiologic factor in each, and [illegible] where the gonococcus is the causative agent. 3. Define ure-[illegible]icle. Give symptoms and treatment. 4. Name causes and [illegible]nt for dysuria. 5. In the early stage of cancer of the [illegible] objective symptoms would you find to make you suspect same? How would you confirm the diagnosis, and what would be your treatment? 6. What anatomic changes will take place in order that a retroversion may occur? Give operative treatment for retroversion. 7. Give differential diagnostic points of salpingitis on the right side and appendicitis. 8. What are the more frequent causes of acute pelvic cellulitis? Give subjective and objective symptoms and your treatment. 9. What conditions would lead you to do a uterine curettement? Describe in detail your method of performing same. 10. Differentiate ascites, hydramnios and unilocular ovarian cyst.

THEORY AND PRACTICE OF MEDICINE

1. Give the physical signs, symptoms and treatment of pulmonary tuberculosis in the early stage of the disease. 2. Give differential diagnosis of variola and varicella. 3. Differentiate between chronic interstitial and chronic parenchymatous nephritis. Give prognosis of each. 4. Describe the physical signs of each stage of pneumonia and give treatment of each in robust subject. 5. Give symptoms and treatment of cerebrospinal meningitis. 6. Give etiology, symptoms, prognosis and treatment of rachitis. 7. Give normal location of apex beat of the heart and give diagnostic symptoms of its various displacements. 8. What are the more common causes of ascites and from what other abnormal conditions must it be differentiated? 9. Give differential diagnosis of measles and scarlet fever, and treatment of the latter. 10. What are the symptoms, prognosis and treatment of hysteria?

Book Notices

The Healthy Marriage. A Medical and Psychological Guide to Wives. By G. T. Wrench, M.D., B.S. Cloth. Price, $1.50 net. Pp. 300. New York: Paul B. Hoeber, 1914.

Sexual Ethics: A Study of Borderland Questions. By Robert Michels, Professor of Political Economy at the University of Basle. Cloth. Price, $1.50 net. Pp. 296. New York: Charles Scribner's Sons, 1914.

For Girls and the Mothers of Girls. A Book for the Home and School Concerning the Beginnings of Life. By Mary G. Hood, M.D., with an Introduction by Sarah Louise Arnold. Cloth. Price, $1 net. Pp. 157, with illustrations. Indianapolis: Bobbs-Merrill Company, 1914.

Ten Sex Talks to Boys (10 Years and Older). By Irving David Steinhardt, M.D., Instructor in Clinical Surgery, Cornell University Medical School. Cloth. Price, $1 net. Pp. 187. Philadelphia: J. B. Lippincott Company, 1914.

Ten Sex Talks to Girls (Fourteen Years and Older). By Irving David Steinhardt, M.D., Instructor in Clinical Surgery, Cornell University Medical School. Cloth. Price, $1 net. Pp. 193, with 6 illustrations. Philadelphia: J. B. Lippincott Company, 1914.

Women and Morality. By a Mother. Men and Morals. By a Father. The Sexes Again. By C. Gasquoine Hartley. Introduction by Wallace Rice. Cloth. Price, $1 net. Pp. 102. Chicago: The Laurentian Publishers, 1914.

Teaching Sex Hygiene in the Schools. By E. B. Lowry, M.D. Cloth. Price, 50 cents. Pp. 94. Chicago: Forbes & Co., 1914.

It is to be expected that the widespread discussion of sex questions and sex instruction that has been prevalent during the past two or three years would produce a considerable amount of literature. The books listed above represent a small portion of the recent output and are typical publications on this subject. The entire question of sex relations is so complicated by personal, religious and conventional prejudices and so modified by experience, temperament and point of view as to make dogmatic assertions on this subject particularly dangerous. What the outcome of the present agitation will be, as far as modification of our ideas as to sex relations, education of children and social conventions, it is impossible to say. Perhaps the wisest plan to follow is simply to chronicle the appearance of different books on this subject, leaving it to each individual to select the literature which comes nearest to meeting his needs.

"The Healthy Marriage" appears to be an earnest effort to supply the lay reader with a moderate, sane, practical book which will furnish the information needed without sensationalism or exaggeration. Besides advice on marriage, the book contains much valuable information on exercise, personal habits and the securing of sanitary surroundings. It can be safely recommended by the physician to the patient desiring reliable information.

Michels' book is a frankly philosophic discussion of the problems involved in sexual relations. The point of view is essentially Continental, and probably many of the author's assertions and conclusions would be unacceptable to the average American reader.—The book is one for the student rather than for the public.

Dr. Mary G. Hood's book "For Girls and the Mothers of Girls" is an elementary presentation for girls of the school age. There have been many efforts in this direction, each of which has had its merits and weaknesses. Each writer on this subject has her own conception of the manner in which it should be presented, and by the same token probably each writer finds readers who are particularly attracted by the manner of presentation. Perhaps in the future we may be able to standardize our ideas of instruction on these subjects. To-day the number of books in this field is the best evidence of diversity of opinion as to the best method of presentation.

Dr. I. D. Steinhardt has made two contributions to this field, one for girls and one for boys. The books originated in talks to audiences of Jewish boys and girls in New York. They are in the form of ten talks or lectures, each followed by ten review questions covering the subject matter.

The little volume on "Women and Morality" contains three essays, the first two being anonymous and the third by Mrs. Walter Gallichian. The three essays originally appeared in the *English Review* for July, August and September, 1913. The discussion, which is essentially from an English point of view, is interesting on account of the brilliancy of method rather than for any real contribution to the problems involved.

Dr. Lowry's "Teaching Sex Hygiene in the Public Schools" does not adhere closely to the title, but touches on many related questions such as "White Slavery," "The True Relations between Mothers and Daughters," "The Dangers to Boyhood," "Blindness of Parents," etc. Several of the chapters appeared first as separate articles in different medical journals. The book impresses the reader as being hastily and rather carelessly put together.

Practical Sanitation. A Handbook for Health Officers and Practitioners of Medicine. By Fletcher Gardner, M.D., Captain Medical Corps, Indiana National Guard, and James Persons Simonds, B.A., M.D., Professor of Preventive Medicine and Bacteriology, Medical Department, University of Texas. Cloth. Price, $4. Pp. 403, with 37 illustrations. St. Louis: C. V. Mosby Company, 1914.

The authors have endeavored to provide, within the confines of a single, moderate-priced volume, a plain, non-technical presentation of the duties of the local health officer and to furnish information for the health officer to meet any emergency which may arise. It is not intended for the specialist or the sanitarian who has access to a large library. The growing tendency of smaller towns and counties to provide for health supervision of some sort makes the need for such a work. The book is divided into three general parts, on epidemiology, general sanitation and laboratory methods. In the first part, after a general discussion of the nature of infection, chapters are given to the management of epidemics, isolation and quarantine, the construction and maintenance of isolation hospitals and camps, and disinfection. The different groups of diseases coming under the jurisdiction of the health officer are then discussed. Under the typhoid group, for instance, are considered typhoid, paratyphoid, mountain fever, amebic dysentery, bacillary dysentery and Asiatic cholera. The other groups discussed are the exanthemas group, the diphtheria group, the plague group, the yellow fever group, the septic group, the tuberculosis group, the typhus group, the meningitis group, the venereal group, the ringworm group, the conjunctivitis group and the animal parasites group. This method of grouping contagious diseases in classes of diseases requiring similar treatment and management has obvious advantages. Under each disease, the cause, pathology, method of transmission, diagnosis, quarantine and disinfection methods and methods for community prevention are considered. The section on general sanitation discusses the organization of sanitary forces, methods of keeping records, methods of inspecting schools, factories and institutions, methods for carrying on special campaigns against rats, flies, mosquitoes, etc., and methods for the disposal of sewage and garbage and for the inspection of water and milk. The third part of the book is devoted to a description of practical laboratory methods. The introduction is by Dr. J. N. Hurty, Health Commissioner of Indiana.

Miscellany

Foot-and-Mouth Disease

Foot-and-mouth disease (see editorial on same subject, this issue, page 1776) is also known as epizootic aphtha, aphthous fever, infectious aphtha, aphthae epizooticae; *Maul-und-Klauenseuche, Aphthenseuche, Mäulfaule,* by the Germans; as fièvre aphtheuse, cocotte, by the French; and as *afta epizootica, febbre aftosa,* by the Italians. The contagious nature of foot-and-mouth disease was recognized before 1764, but until the growth of bacteriology it was associated with spoiled feed, bad air and various climatic influences. Various organisms, including bacteria or protozoa, have been suggested as the cause of the disease. In 1897 Löffler and Frosch showed that the contagious material passed through porcelain filters, and therefore put it in the class of filterable viruses. Recently Siefel has connected with the disease certain cocci, which he found in the blood of infected animals, in the vesicles, in the plasma, and in the heart muscle, and his findings have been duplicated by others. The disease infected eastern Europe, and in various wars was spread to western and central Europe. It has occurred at periodic intervals, when it usually has spread over all the countries, and after two or four years subsided. Great Britain, Germany, France, the Netherlands, Austro-Hungary, Russia, all have in turn suffered from it. The loss from this disease in England in 1883 was estimated at $5,000,000. In an epidemic in Germany in 1890, about 500,000 cattle, 250,000 sheep and 150,000 swine were infected with it.

The disease reached Canada through an importation of cattle from England to Montreal in 1870; from this point it spread to the New England states, New York and New Jersey, when this large epidemic was effectively checked. In 1902 an outbreak threatened great danger, but following the destruction of all infected and exposed herds, together with proper quarantine measures, the disease was limited to four of the New England states. At various times there have been small outbreaks following the importation of infected animals. The last large outbreak to occur in the United States was in 1908. At this time the disease was discovered in some Pennsylvania cattle. Investigations by the government showed that cow-pox vaccine virus, imported from a foreign country, was contaminated with foot-and-mouth disease. This vaccine was employed for the production of vaccine in calves which then became infected with foot-and-mouth disease. Another concern purchased some of the contaminated vaccine and infected its own calves. The calves of the second firm were then sold in the open market and started the epidemic; those of the first firm having served their purpose for the production of vaccine had been killed. The government immediately had all the vaccine recalled, and using the usual vigorous measures, was able to check and eradicate the epidemic. This particular instance cost the federal government $300,000. There are no records which show transmission to man of foot-and-mouth disease by means of small-pox vaccine, and it is extremely doubtful if such transmission is possible by the ordinary method of vaccination.

In the epidemic of 1908 Michigan, Pennsylvania, New York and Maryland were affected. "Since that time," says Eichhorn, of the Bureau of Animal Industry, "this country has been free from the disease and with the quarantine prescribed by law for imported animals and the present requirements of testing all importations of vaccine lymph for possible contaminations of foot-and-mouth disease, there appears to be little danger of the introduction of the disease into this country" (Reference Handbook of the Medical Sciences, Iv, 504).

In the present epidemic of foot-and-mouth disease, which concerns practically the entire Mississippi Valley, the chief interest is centered in the outbreak in the large Chicago Stock Yards. Up to November 9—quarantine of the stock yards having been instituted November 7—912 head of cattle valued at $52,000 and 160 hogs valued at $2,000 were slaughtered and buried in quicklime in the stock yards. The work of disinfection consisted of a liberal use of creosote, lime and phenol (carbolic acid). Ten states are under federal quarantine and two others are about to be quarantined. It was found unnecessary to slaughter any of the prize stock in the exhibit at Chicago, all of them being quarantined and under treatment; none of them were affected with the disease in a severe form. The history of the epidemic as given by Secretary Houston is as follows: The disease appeared at Niles, Mich., about October 12, and went to the Chicago Stock Yards in a shipment of hogs. From the stock yards it was carried broadcast for over two weeks before steps were taken to limit it. The present epidemic covers five times as much territory as any other former epidemic. Railroads are disinfecting all stock cars. The embargo over the Chicago Stock Yards will cover a period of one week.

In many of the European countries the spread of the disease is checked by allowing all the animals in a single herd to be infected, holding them under quarantine and waiting for them all to die or to recover. More recently it has proved of advantage to destroy all animals of the infected herd and those that have been exposed, at the same time instituting a rigid quarantine and disinfecting the buildings in which the diseased animals have been kept.

The disease is rarely fatal in man, but has been known to be fatal to children. It is not carried by meats but may be transmitted by milk, butter or cheese. Milk that is not pasteurized and cheese that is not made from pasteurized milk may be carriers of the disease.

First Aid to Those Overcome by Mine Gases, Electric Shock, Etc.

The Bureau of Mines, in publishing the report of the Committee on Resuscitation from Mine Gases (Technical Paper 77), recommends the following procedure in giving first aid to those in need of artificial respiration:

"In case of gassing, remove victim at once from gaseous atmosphere. Carry him quickly to fresh air and immediately give manual artificial respiration. Do not stop to loosen clothing. Every moment of delay is serious.

"In case of electric shock, break electric current instantly. Free the patient from the current with a single quick motion, using any dry non-conductor, such as clothing, rope or board, to move patient or wire. Beware of using any metal or moist material. Meantime have every effort made to shut off current.

"Attend instantly to the victim's breathing. If the victim is not breathing, he should be given manual artificial respiration at once.

"If the patient is breathing slowly and regularly, do not give artificial respiration, but let Nature restore breathing unaided.

"In gas cases, give oxygen. If the patient has been gassed, give him pure oxygen, with manual artificial respiration.

"The oxygen may be given through a breathing bag from a cylinder having a reducing valve, with connecting tubes and face mask, and with an inspiratory and expiratory valve, of which the latter communicates directly with the atmosphere.

"No mechanical artificial resuscitating device should be used unless one operated by hand that has no suction effect on the lungs.

"Use the Schäfer or prone-pressure method of artificial respiration. Begin at once. A moment's delay is serious.

"Continue the artificial respiration. If necessary, continue two hours or longer without interruption until natural breathing is restored. If natural breathing stops after being restored, use artificial respiration again.

"Do not give the patient any liquid by mouth until he is fully conscious.

"Give him fresh air, but keep his body warm.

"Send for the nearest doctor as soon as accident is discovered."

A limited number of copies of the report may be obtained free from the Bureau of Mines, Washington, D. C.

Practicing Medicine Without a License Punishable Under Statute

(State vs. Nelson (La.), 65 So. R. 893)

The Supreme Court of Louisiana says that the bill of information filed against the defendant charged him with practicing medicine without a license. He filed a motion to quash the information on the ground that no provision is contained in the statute to punish those who practice without a license. The motion was granted and the Supreme Court affirmed the judgment of the lower court. A rehearing was obtained, and on the rehearing the judgment was reversed.

In its first decision the Supreme Court held that the defendant's contention that Act 49 of 1894 is unconstitutional because its title is not broad enough to cover a prosecution for practicing medicine without a license, was not well founded, as the title of the act recites that it is an act "to regulate the practice of medicine" and "to provide punishment by fine or imprisonment or both." But the court further held that an act, amending an act which has already been repealed, is absolutely without force as the amendment has no foundation on which to rest; and, as Section 14 of Act 49 of 1894 had been repealed by Act 13 of 1898, the attempt to amend Section 14 of Act 49 of 1894 by the passing of Act 244 of 1908 was abortive, and did not have the effect of giving any force to Section 14 of Act 49 of 1894. On the rehearing, however, the court holds that the objection that a statute, purporting to amend and reenact a section of an existing statute, is inoperative because the section in question has already been amended and reenacted by, and merged in, another statute, will not be sustained where the title of the amendatory statute not only declares the purpose to amend, but goes farther and specifically and affirmatively declares the object to be accomplished by the amendment. Act 244 of 1908 is not, therefore, obnoxious to the objection that its object is not declared in its title, or to the objection that it is an ineffectual attempt to amend a nonexistent provision of law, since its title gives it a status as independent legislation.

The title of Act 16 of 1912, at which, also, the defendant's motion to quash was directed, merely declares its object to be to "amend" Sections 5, 11 and 14 of Act 49 of 1894, entitled "An Act to regulate the practice of medicine," etc. The declaration is sufficient as to Sections 5 and 11, but insufficient as to Section 14, which had previously been amended and reenacted by Act 13 of 1896, and superseded by Act 244 of 1908. Another objection, in so far as Section 14 is concerned, is that the title of Act 16 of 1912 refers to criminal prosecutions only, whereas the body of the act provides also a civil proceeding by injunction.

Liability for Patient Under Own Physician Getting Poison in Hospital—Evidence

(Broz vs. Omaha Maternity & General Hospital Association (Neb.), 148 N. W. R. 575)

The Supreme Court of Nebraska affirms a judgment for $7,000 damages against the defendant hospital association for the death of a patient from poison. The patient, who suffered intermittent mental infirmities, was under the care of his own physician. In the absence of his physician, wife, relatives and friends, he found and took some mercuric chlorid tablets. The court says that the pleadings, evidence and circumstances justified a finding that the patient was admitted to the hospital under an implied obligation that he should receive such reasonable care and attention for his safety as his mental and physical condition required. The physician employed by him did not relieve the hospital of responsibility for negligence on its part, if any. The patient was under the personal observation of his physician only a small portion of the time. In the latter's absence and drug emergencies he was under the care of the nurses and the intern who were employees of the hospital. Within the scope of their employment their employer was legally responsible for their negligence to a patient. The patient's physician did not manage or control the hospital, and he was not liable for the negligence of hospital nurses and interns, if he had no connection with any negligent act.

At night, during the absence of the patient's physician, it was clearly the duty of the hospital intern, who was a physician, and the nurses in charge, to give such treatment and attention as the emergency demanded, when known. The defendant was prepared for such an exigency. One of the purposes of a hospital in assuming control of a patient, for private gain, is to furnish promptly modern equipment, facilities and treatment. To avail himself of these advantages the patient left his home and intrusted himself to the care of the defendant. The duties which such a hospital owes to a patient are commensurate with the responsibilities assumed. The approved rule is that a patient is generally admitted to a hospital, conducted for private gain, under an implied obligation that he shall receive such reasonable care and attention for his safety as his mental and physical condition, if known, may require.

It was said that the physician employed by the patient instructed the defendant to allow him the freedom of his room and the halls, that employees of the defendant did so, and that it was not chargeable with negligence for complying with instructions. The directions of the physician should be considered with the duty of the hospital to give the patient such reasonable care and attention for his safety as his mental and physical condition required. The defendant was not instructed to allow the patient, who had been suffering from a fitful mental disorder, access to a hospital sinkroom, where poison, in the form of medicine tablets, was kept. Whether there was negligence in allowing the patient access to such a place in the night, while unattended, was a question for the jury.

Where a hospital patient takes poison at night in the absence of his physician and friends, while he is under the exclusive care of nurses and interns, harsh and technical rules of evidence should not be enforced to exclude proper testimony tending to throw some light on material facts which, on account of the pecuniary interests and the reputation of the hospital, there might be a temptation to conceal.

In considering the reasonableness of the amount of damages awarded, it is held that a mere fitful or temporary mental disorder will not be presumed to continue.

What Constitute Communications to Physicians and Waivers of Privilege

(Ausdenmoore et al vs. Holzback (Ohio), 106 N. E. R. 41)

The Supreme Court of Ohio holds that there was no error in sustaining the objection of plaintiff Holzback to certain physicians testifying for the defendant as to a diagnosis they had made of the plaintiff's physical condition. Section 11494 of the General Code of Ohio provides: "The following persons shall not testify in certain respects: . . . Or a physician, concerning a communication made to him by his patient in that relation, or his advice to his patient." The court holds that a communication by the patient to the physician may be, not only by word of mouth, but also by exhibiting the body or any part thereof to the physician for his opinion, examination, or diagnosis, and that that sort of communication is quite as clearly within the statute as a communication by word of mouth. But the same section further provides that the physician may testify by express consent of the patient, and if the patient voluntarily testifies the physician may be compelled to testify on the same subject. This qualifying clause the court holds to mean that there cannot be a waiver except in two ways: First, by an express consent of the patient, or by the patient taking the stand and voluntarily testifying as to the things and matters communicated to his physician, the latter being held to be in effect an express waiver as to that physician. There was neither form of waiver in this case.

The President, Dr. D'Orsay Hecht, Chicago, in the Chair

Factors Which Determine the Advisability of Prostatectomy

Dr. William F. Braasch, Rochester, Minn.: With stone in the bladder it is usually advisable to remove the stone and drain the bladder for a time prior to prostatectomy. Stone in the bladder may cause temporary enlargement of the prostate. Pyelonephritis is a frequent complication of bladder drainage and a strong resistance should be established before attempting operation. The renal condition is better estimated prior to operation by clinical evidence than by laboratory tests. Cystoscopic examination, while valuable in certain conditions, may be the cause of harm if used as a routine procedure. Urethroscopic examination is occasionally of greater value than cystoscopic examination. It is particularly valuable with intra-urethral hypertrophy and with carcinoma.

DISCUSSION

Dr. William N. Wishard, Indianapolis: Twenty-four years ago I emphasized the importance of preliminary drainage in cases of prostatic obstruction where bladder infection existed and where kidney function was impaired.

Dr. French Cary, Chicago: Cystoscopic examination is of assistance in determining hypertrophy in different portions of the prostate. All cases should be given a functional test before operation and if the test is low, drainage should be instituted.

Dr. Charles E. Barnett, Fort Wayne, Ind.: In cases of malignant prostate, if the gland is very large and must be taken out, it is wrong to cystoscope the patient and traumatize the tissues, thus infecting the patient still more.

Dr. Bransford Lewis, St. Louis: Many cases of prostatic obstruction are not improved by operation. They are cases of acute, almost complete, obstruction from contracture which can be relieved by palliative measures.

Dr. Gustav Kolischer, Chicago: There are cases in which prostatectomy is indicated, although retention of urine may not be very acute, and there is no hyperdilatation of the bladder, and no infection. One condition which frequently is overlooked is an infiltrating cystitis that extends to the bladder wall from the mucosa and perivesical tissue. If we drain the bladder we are not going to influence the infiltration which is an infectious, inflammatory infiltration of the two coats of the bladder wall. There is only one way of relieving this condition, and that is to make an extensive incision, stripping this infiltrated tissue just as we deal with an infiltrating phlegmon in any other part of the body.

Hemolysis, Following Transfusion of Blood

Dr. Bertram B. Bernheim, Baltimore: In eight hundred reported transfusions there were fifteen instances of macroscopic hemolysis. In these fifteen cases there were eleven recoveries and four deaths. No hemolytic tests were made in three of the instances where death occurred. In the fourth case tests were made and it was known that the donor's cells were slightly agglutinated by the patient's serum, but since agglutination is an entirely different process from hemolysis, and since no other donor was available, it was considered fairly safe to use this donor, and a fatality occurred. Tests were made in eleven of the fifteen recoveries, and in nine instances hemolysis was prognosticated. The dangers of transfusion are immediate and delayed. The immediate is acute dilatation of the heart consequent on an inflow of blood of such force and rate that the recipient's heart is overwhelmed. The delayed danger is that of hemolysis, which can be prognosticated in practically every instance by careful tests prior to transfusion. In emergencies no thought should be given to hemolysis or anything else. Far better is it to transfuse immediately and save a patient from imminent death, running the slight risk of a late hemolysis, than to temporize with tests which require at least two hours for their proper performance. Where, however, there is time, and in the majority of instances such is the case, failure to have the tests made is an inexcusable blunder.

Radium in Treatment of Cancer of Uterus

Dr. J. Louis Ransohoff, Cincinnati: Radium is of undoubted value in cancer of the uterus to control hemorrhage, discharge and pain, and in causing the local disappearance of the disease. If possible, radium should be used in all cases of inoperable cancer of the uterus when the patient is not in the extreme stage of emaciation and cachexia.

Renal Infections from Bacteriologic Point of View

Dr. Irvin S. Koll, Chicago: The accepted three routes of infection are the lymphogenous, hematogenous and urogenous. Knowledge of the lymph channels draining from the intestinal tract into the kidney accounts for the frequency of infections of the kidney associated with acute and chronic gastro-intestinal disturbances. Infections through the ureter may be either extra- or intra-ureteral. Of particular importance is the pyelitis associated with pregnancy, the frequency of which is estimated as high as 20 per cent. Of late the hematogenous route seems to have been neglected in the consideration of the carriage of bacteria to the kidney. The circulatory system is a carrier of bacteria of as great importance as the lymph stream.

DISCUSSION

Dr. Hugh Cabot, Boston: The milder grades of infection of the kidney, commonly miscalled pyelitis, are extraordinarily more common in females than in males, even among children. This should not be regarded as accidental, and yet this has never been explained satisfactorily.

Dr. Edward C. Rosenow, Chicago: Primary pyelitis is rare. It is a pyelonephritis or nephritis infecting the pelvis of the kidney secondarily. The results I have had from the intravenous injections of streptococci make me feel strongly that given a case of acute pyelitis or pyelonephritis, no matter what the organism is primarily, it is a hematogenous infection that primarily infects the capillaries and secondarily infects the pelvis of the kidney.

Dr. Emil Ries, Chicago: Cases of so-called pyelitis said to have been cured were really not cases of pyelitis at all, but cases of pyelonephritis. Cases of so-called pyelitis of pregnancy came under my observation rather frequently in years gone by. They were treated on the conservative plan, and the vast majority of the patients got well.

Dr. Bransford Lewis, St. Louis: Lavage, using a fluid that has certain medicaments incorporated in it that have germicidal properties, will cure infections of the renal pelvis.

Gastric and Duodenal Ulcer

Dr. C. W. Dowden, West Baden, Ind.: Of 425 cases of gastric and duodenal ulcer, 170, or 40 per cent., bore a definite relation to some infection, and I conclude that this is the chief etiologic factor. Ulcers pass through a stage which is distinctly medical, and if diagnosed at this time are amenable to treatment. Surgical ulcers are those that have involved more than one coat of the gastric mucosa. Medical treatment at this time is worse than useless because the patient mistakes temporary relief for cure. An active ulcer in its early stage is best treated by absolute rest to the stomach, controlling painful peristalsis by antispasmodics, and by rectal feeding until the acute stage has passed. All foci of infection, no matter where located, should be removed.

DISCUSSION

Dr. Charles D. Aaron, Detroit: In the treatment of gastric ulcer, when it is complicated by vagotonia, the treatment of both conditions will give a better result than if we treat only the ulcer. We have all had cases of healed ulcer of the pylorus, with contraction or stenosis of the pylorus, dilatation of the stomach, visible peristalsis when the stomach was endeavoring to empty itself. We operate and what do we find? Not an ulcer but obstruction of the pylorus. A gastro-enterostomy is done and the patient recovers. Why in such cases do we not have chronic ulcer of the stomach?

Dr. Charles A. L. Reed, Cincinnati: Little regard has been paid to one of the most important etiologic factors, namely, chronic intestinal stasis. Too little attention is being given to the conditions within the stomach proper, to the nerve conditions back of the stomach action, and to the various distinctly local causes as they apply directly to the pylorus or to the duodenum. In the majority of cases the difficulty lies in favor of normal physiologic drainage of the duodenum and stomach, thus inducing infection which in turn induces ulceration. I have demonstrated this in a considerable number of cases. I have latterly tried to establish drainage in the lower segment of the intestinal tract, and with what results? The ulcer disappears.

Dr. C. W. Dowden: I am fully in accord with everything Dr. Reed said as to the important rôle intestinal stasis plays in the production of gastric and duodenal ulcer.

Colon Stasis

Dr. Joseph R. Eastman, Indianapolis: Treatment directed at the relief of chronic colitis will affect also the attendant ptosis and stasis and likewise the associated plastic peritonitis. Properly performed short-circuiting operations by the improved drainage which they provide relieve chronic colitis and indirectly affect favorably the other factors of stasis — ptosis and peritonitis. The feces are to a considerable extent made up of epithelial debris, intestinal secretions and dead and living bacteria, and these things mixed with food residue under the influence of contractions of the cecum rise in the ascending colon. But this contraction is not constant. The empty cecum is in repose; it does not contract. It is only awakened when the small intestine empties into the cecum its liquid contents. If contractions are not produced in this way, the feces have no tendency to be evacuated. The colon becomes lazy and atonic and obstipation is increased by antiperistalsis. It is for this reason that ileosigmoidostomy may be said to be conceived falsely. By this operation the liquid contents of the small intestine are not permitted to enter the cecum to bring about contraction. It is for this reason that Lane and others have been obliged to reoperate after ileosigmoidostomy and deal with an enormous fecal accumulation in the cecum and ascending colon. Typhlo-sigmoidostomy or typhlo-proctostomy are not open to the above criticisms, for in these operations the fluid contents of the small intestine are permitted to enter the cecum. In a case of simple constipation concerning only the left colon, ileosigmoidostomy may be of some benefit, but it is debatable whether such a condition is not better treated by non-surgical means. Bergmann first anastomosed the cecum to the sigmoid for volvulus of the ascending colon and the operation in cases of stasis is not indicated unless membranes or adhesions so fetter the colon as to make such an exclusion necessary because of incompetency or obstruction. If the colon is obstructed at the hepatic or splenic angles alone, then colocolostomy, as practiced by Payr, which excludes these flexures alone is of obvious use. Sigmoidoproctostomy for the exclusion of redundant sigmoid may often be employed with advantage to supplement the anastomosis of the caput coli to the rectum or the redundant sigmoid may be treated by the Troyanoff-Winiwarter anastomosis between the loops of the sigmoid or eventually the redundant colon may be resected. At any rate, after typhlo-proctostomy, coils of redundant sigmoid cannot with safety be left above the stoma. Montprofit's operation of dividing the terminal ileum and anastomosing both ends end-to-side with the sigmoid represents no improvement over simple typhlo-proctostomy. Here an attempt is made to drain the excluded cecum in defiance of the ileocecal valve through the short stump of the ileum, whereas this can be accomplished more simply and more completely by a large stoma in the floor of the cecum.

DISCUSSION

DR. JOSEPH RANSOHOFF, Cincinnati: Colon stasis does exist, but in a large number of individuals it produces no deleterious results whatever. In a very small number of cases colon stasis is followed by pathologic conditions. It has been said that idiopathic epilepsy may be brought on by colon stasis. It is a tremendously far cry from colon stasis to epilepsy. Idiopathic epilepsy is a condition which begins exceedingly early in life in the form of *petit mal*. I cannot believe that there is any possible connection between colon stasis and epilepsy.

DR. WILLIAM SEAMAN BAINBRIDGE, New York City: Lane emphasizes that nineteen cases out of twenty of intestinal stasis ought never to be operated, and yet men are saying that Lane performs colectomy, ileocolostomy, etc., on this class of patients. He does not.

DR. LOUIS J. HIRSCHMAN, Detroit: Postural treatment, special localized exercise, etc., will cure many cases of intestinal stasis. Give these patients Russian oil for months; it cures many of these patients. When they do not respond to these methods of treatment, operate.

DR. J. RAWSON PENNINGTON, Chicago: Colon stasis is a symptom, not a disease. The treatment for colon stasis is to remove the obstruction and then the stasis disappears. It does not make much difference what operation you do.

Use of Abderhalden Reaction with Normal and Pathologic Serums

DR. ELLISON L. ROSS and DR. H. DOUGLAS SINGER, Kankakee, Ill.: Our results, briefly, are as follows: 1. Paretic serum: With 2 washings 10 serums all gave positive results; with 3 washings 6 were all positive; with 5 washings 8 of 11 were positive; with 10 washings 1 of 3 was positive; with 11, 2 of 8; with 13, 14 and 15 washings none of 20 were positive. 2. Normal serum: With 2 washings 8 were all positive; with 3 washings 1 of 4 was positive; with 5, 8, 10, 11, 13, 14 and 15 washings a total of 34 serums all gave negative results. It was also demonstrated that the water used for the washing of substrates contained material which underwent lysis when mixed with blood serum. Hence, in order to determine whether there is any specific difference between the ferments present in general paresis and the normal state, the water used for the fifth and eighth washings was concentrated and used as a substrate. In spite of the failure of normal serum to digest brain substrate which had been washed 5 times or more, normal serum caused lysis of the material in this wash-water fully as markedly as did that from cases of general paralysis. From these facts it is evident that no interpretation of the results of Abderhalden tests with tissue substrates is justifiable unless the same (not merely similarly prepared) substrate has been proven to give negative results with a series of normal serums.

Modern Syphilis Therapy and the Central Nervous System from a Biologic Point of View

DR. CARL D. CAMP, Ann Arbor, Mich.: The treatment of tabes and paresis is probably the most important part of the treatment of syphilis of the nervous system. These diseases, while due to syphilis, have other determining factors. Intravenous injections of salvarsan have an effect in some cases. Intradural injections of salvarsan have greater effect on the spinal fluid findings but are distinctly dangerous. The Swift-Ellis treatment seems to vary in effectiveness with different observers; the more conservative do not find any greater improvement than with intravenous injections. The rationalé of this treatment is not very clear. The use of mercury by injections is probably as effective as any method of treatment and has less possibility of harm. Cases of tabes dorsalis frequently become stationary under mercurial treatment, the spinal fluid findings either showing improvement or else no change.

2. Hereditary Syphilis.—Jeans and Butler emphasize that as a social problem, hereditary syphilis assumes relatively large proportions, one patient often representing a number of individuals needing treatment. Parents are frequently indifferent and fail to continue treatment. They also frequently fail to see the importance of having Wassermann tests made on the other children of the family, who may seem perfectly well, but who may have syphilis. In the case of such parental indifference the authors suggest that such tests or treatment should be enforced.

Hereditary syphilis is more frequent in illegitimate than legitimate children. The mortality is higher in illegitimate syphilitic infants than legitimate syphilitic infants. Hereditary syphilis in St. Louis is from two to three times as frequent in the colored as in the white race. The frequency of hereditary syphilis is greater among the infants in our clinic than among the older children. The waste in potential life by miscarriages and deaths in syphilitic families is twice as great as in non-syphilitic children.

Thirty-three per cent. of the syphilitic children over 1 year examined by Jeans and Butler had permanent disabling damage. Eighteen per cent. of the syphilitic children over 1 year had long-continued temporary disabling damage. There is about five times as much feeble-mindedness in syphilitic families as in non-syphilitic families. The mortality for artificially fed syphilitic infants is five times as high as for breast-fed syphilitic infants, not including deaths due to intestinal disturbances.

5. Tuberculosis.—An analysis of 178 cases of tuberculosis occurring in children less than 5 years of age (75 per cent. under 2 years) was made by Wollstein and Bartlett. In five instances the tuberculous lesions were found to be limited to the bronchial lymph-nodes, only one node being involved in each of three cases, and two and three nodes in the other two cases, respectively. These children were between 17 and 27 months old. The lesion was an active one in every case. There were two children in whom the tuberculous lesions were limited to one lung and the adjacent bronchial lymph-nodes. One of these was a 4-months-old girl, the other a boy of 3 years. One child, 20 months old, had but one other tuberculous focus besides that in the bronchial lymph-nodes. In this case several fingers were the seat of a dactylitis, apparently tuberculous. As examples of pulmonary tuberculosis with beginning generalization through the blood-stream, was an 18-months-old child in which there was tuberculosis of the lungs, bronchial lymph-nodes and spleen, and another in which tubercles were found in the liver, spleen and pia mater, in addition to the lungs. The presence of recent tuberculous ulcers in the intestines in a boy 18 months old with an older infection in the lungs and bronchial glands suggested infection of the intestine through swallowing of tubercle-bacilli-laden sputum rather than blood generalization. By far the greater number of cases in this series fall into the group of primary pulmonary infection with markedly generalized tuberculosis by way of the blood. There were 134 cases of this kind, the lesions in the lungs and bronchial lymph-nodes being older than those in any other organ.

The lungs were free from tuberculosis in only 14 of the 178 cases. Calcareous degeneration was found in the lungs only five times. Pulmonary cavitation was present in forty-three children. One child presented cheesy tubercles in one mesenteric lymph-node, without any other tuberculous focus in the body. In one infant, 9 months old, the mesenteric and cervical nodes were equally large and cheesy, while one deep cervical node contained a calcareous area; one tuberculous ulcer was found in the jejunum. In two cases the cervical lymph-nodes showed as old a tuberculous focus as that found in the mesenteric nodes and intestines, while the liver and spleen and lungs contained but few young, miliary tubercles. Thirteen other cases presented the oldest lesion in the mesenteric lymph-nodes, whence more or less completely generalized infection had occurred. One child of 2 years, besides cheesy tubercles in several mesenteric glands, had miliary tubercles in the liver, peritoneum and pia mater. The involvement of the pia mater before that of the lungs and spleen is noteworthy. Six of the thirteen cases in which the mesenteric glands contained the oldest lesion were accompanied by tuberculous peritonitis. With one exception, a child of 7 months, all the cases of peritonitis occurred in children 21 months to 4 years of age.

There were only 14 cases in which the lungs were not involved. In the entire series of 178 cases there were only 9 in which the bronchial lymph-nodes contained no evidence of tuberculosis. In three the lungs were also free. In the remaining six there were tuberculous lesions in the lungs, but the primary focus was in the gastro-intestinal tract. The mesenteric lymph-nodes, on the other hand, were the seat of a tuberculous lesion in 113 of the 178 cases. In only 17 of these 178 cases were the mesenteric gland lesions the most advanced in the body, and in 4 of the 17 the intestines were not involved. Tuberculous meningitis occurred in 69, or 38 per cent., of these children. The distribution of the lesions in these cases shows that the younger infants tend to have a larger number of viscera involved in the tuberculous process, while in the older children meningitis may follow a limited infection. The younger infants have a more generalized tuberculosis and the older children have a more localized infection.

The most generalized cases had tubercles in the skin, myocardium, peritoneum, mesenteric glands, intestines, kidneys, liver, spleen, bronchial glands, lungs and pia mater. This occurred in two infants, 3 and 5 months of age. Of these sixty-nine cases of meningitis, three were of intestinal origin: The largest number of cases were of inhalation origin, as shown by the large percentage of cases in which the pulmonary lesions were the most advanced in the body. The absence of tuberculous lesions from the lungs in fourteen cases and the presence of tuberculous lesions in the bronchial lymph-nodes in seven of these seems to show that it is possible for the tubercle bacillus to pass through the lungs without localizing there.

7. **Scoliosis.**—With a child whose bony tissue is abnormally malleable, if the equilibrium of the forces of the spinal column is, from any cause, disrupted, Calve believes that the ensuing scoliotic deformation is perhaps readily explained. The rupture of the equilibrium is manifested by a curvature of the vertebral column. Because of the softness of the bony tissue, this curvature causes a deformation of the bodies of the vertebra, and this deformation makes the curvature permanent. The weight of the patient increases the curvature and rotation is started. The lateral deviation vertebra causes the bending of the rib, and this bending increases the rotation.

11. **Transverse Process of Fifth Lumbar Vertebra.**—Within the last two years, seventeen cases with bifurcation of the transverse process of the fifth lumbar vertebra have been recorded in the Mayo clinic. In this series there were three males, aged from 18 to 35, and fourteen females, aged from 9 to 45. Only three gave any symptoms which could be definitely attributed to the condition present. The remaining fourteen cases were discovered accidently in radiographing for other conditions such as lesions of the kidney and ureter, tuberculosis of the spine, congenital dislocation of the hip, etc. In four cases, the condition occurred on both side, seven on the right and six on the left. One case only was operated on; relief was but temporary.

28. **Pulmonary Anthracosis.**—Pulmonary anthracosis (not in coal miners) according to Klotz is distinctly an urban disease, and is proportionate to the smoke content of the air. The soot is inspired and lodges in the pulmonary alveoli, from which it carried by phagocytes into the lung tissue to become lodged in some portion of the pulmonary lymphatic system. Although small quantities of carbon deposit in the lung may remain without harm, yet the quantity accumulating in the dweller of the larger cities has an accompanying greater or less fibrosis, impairing the elasticity as well as altering the functional capacity of the organ. The distribution of carbon is fairly uniform in the parenchyma of the different lobes, but there is a considerable variation in the distribution of the pleural deposit. The interlobar diaphragmatic pleural surfaces show the least pigment. Moreover, less pigment is found in the grooves produced by the ribs of abnormal bands. Carbon tends to accumulate at the nodal points of junction of the lymphatic channels. The cellular migration of carbon may lead to unusual accumulations in certain areas, particularly well demonstrated in the deposit about chronic tuberculous lesions. Carbon deposits by inducing fibrosis tend to encapsulate chronic tuberculous foci. Pulmonary anthracosis by itself does not appear to stimulate the production of pleural adhesions. The actual amount of carbon present in the lungs of different individuals varies considerably and is dependent, in part at least, on the age, occupation, residence and condition of the lungs (emphysema, collapse, tuberculosis).

31. **Propagation of Amebic Dysentery in Animals.**—The inoculation of infective material from virulent and also from distinctly avirulent cases of amebic dysentery directly into the cecum of kittens has given practically 100 per cent. of infections as compared with the usual result of about 50 per cent. of positive infections when virulent material is fed or injected per rectum. Injections by intracecal methods has been of service in: (1) The continuous propagation of a strain of dysentery. (2) The determination of the etiology of some obscure diarrheas. (3) It also offers certain advantages in diagnosis and in the study of the morphology and biology of the entameba.

Continuous propagation of one strain of dysentery through eleven passages, with a definite increase in virulence and with retention of the typical morphology, has been obtained. Especial attention was given to the following points: (1) Avoidance, as far as possible, of the accompanying bacteria by selection of mucus and blood practically free from fecal matter. (2) Inoculation of ameba obtained during the first day or two of symptoms. (3) Avoidance of diluting agents. (4) Avoidance of degenerated ameba by sacrificing animals, if necessary, and obtaining material from the lesions in the mucosa.

Sellards and Baetjer state that degenerative changes described by Hartmann and by Darling do occur in infected animals, especially in spontaneous stools and in autopsy material, but by sacrificing the animals they were able to demonstrate, in addition to these degenerated forms, an abundance of typical virulent ameba in the lesions in the mucosa. A careful consideration of the possibilities for the loss of a strain of ameba by accident during subpassage in animals leads them to feel definitely that the view, accepted at present, that the subpassage of amebic infection is self-limited, is definitely erroneous.

The clinical course of the disease in animals is strikingly similar to that of human infections: (1) The following features occur both in man and animals: (a) Acute fatal infections; (b) chronic infections with relapses and liver abscess; (c) development of the carrier state. (2) Certain features have not been reproduced in kittens; (a) intestinal amebiasis with extensive lesions without dysentery; (b) rare complications, such as brain and splenic abscess. (3) One important feature, bacterial septicemia, is common in animals, but has not been rigidly established in man. (4) The pathology in man and animals is similar in its fundamental characteristics, but differs in the exact distribution of the lesions. Some obscure diarrheas were investigated by Sellards and Baetjer which were characterized by continuous watery discharges without periods of intermission and with the presence of a few atypical ameba in the stools. From a morphologic standpoint, no etiologic importance could be attached to these ameba. Animal inoculations proved definitely, however, that these organisms were responsible for the symptoms.

34. **Bubonic Plague.**—Given a case in which there is a sudden onset with marked prostration, severe headache, vomiting, high temperature and early delirium, in which there is found a focus of lymphatic enlargement and tenderness, Wade and Staring urge that the possibility of *B. pestis* infection should be considered. The diagnosis of a case cannot, as a rule, be made positive without a bacteriologic study. This is to be carried out on material secured by gland aspiration, smears of which usually show numerous typical bacilli. The rather characteristic growth on different media, with the usual involution forms on salt agar, together with the demonstration of lack of motility and of the habit of producing acid without gas in dextrose media, make the diagnosis so certain that the death of guinea-pigs inoculated with gland material is merely confirmatory. The essential features of sections of the tissues in this infection are acute inflammatory infiltrations, dissolution of connective tissue, hemorrhage, edema and the presence of great numbers of the bacilli in the tissues along the invasion tract.

42. **Influence of Diet on Tumors.**—Rous' experiments show that large growths of certain transplanted rat and mouse tumors are checked in their development by underfeeding the host on a special diet. (Sweet's modification of one of Mendel and Osborne's foods) or in some cases by simple underfeeding. Two metastasizing mouse tumors are instances in point. They stopped growing or grew very slowly in hosts underfed on the special diet. The Flexner-Jobling rat carcinoma, on the other hand, was unaffected by the most rigorous and underfeeding on a mixed diet when this was begun after the tumor had been growing for a short period. Experiments to test the influence of underfeeding on recurrence of this tumor gave results that varied, but the findings strongly indicate that generalizations from work with transplanted tumors as regards the effects of diet on spontaneous growths are unwarranted.

By underfeeding on Sweet's food mice with spontaneous tumors, beginning some days prior to operation, it proved possible in most cases to delay for a relatively long period the development of recurrences and the growth of tumor bits (grafts) disseminated at the time of surgical interference. The treatment entailed great loss of weight. Tumor mice kept on ordinary diet previous to operation, but put thereafter on an abundant ration of Sweet's food, developed recurrences as early as the tumor mice on ordinary diet; whereas the growth of auto-implants was much delayed. These results seem attributable rather to a gradual malnutrition induced by the special food than to the circumstance that it lacked a growth principle. In none of the dieted mice was a definite cure obtained. Ordinarily a recurrence appeared and the grafts began to grow soon after the host, again on ordinary food, had regained weight. A few spontaneous tumors seem absolutely unaffected by the most rigorous dieting.

Rous thinks that it is conceivable that recurrences of certain human tumors and the development of metastases may be delayed or prevented for a period by methods somewhat similar to those employed against spontaneous mouse tumors in the present investigation. But generally speaking only the more malignant human tumors would require such palliative measures, and these are precisely the ones that would prove—if experience with mice is an index—least amenable to alterations in the nutrition of the host.

in both instances by infected lymph, which spread by the same path and therefore attacked the same cells. There is no doubt in their minds that if the capsules in the second series of experiments had not burst the reaction would have been of the plasma-cell type, namely, the type of cells characteristic of the subacute inflammations; but as the capsules had burst and the organisms had grown among the tissues, the reaction was of the polyblast type, namely, the type of the acute inflammations. These cells were the direct product of the action of the disease-producing agent and therefore the conditions corresponded to the primary inflammations of Schmaus. But there were small collections of Körnchenzellen, and the authors are convinced that if the animals had lived a little longer and the nerve elements had broken down under the influence of the more prolonged action of the irritant, the tissues would have been infiltrated by these cells and the conditions would have corresponded to the secondary inflammations of Schmaus.

2. **Hereditary Disease of Nervous System.**—The disease described by Batten and Wilkinson is a familial and hereditary one, having its onset in the first three months of life, even if it is not actually congenital. It presents symptoms which in many respects are similar to those seen in cases of disseminated sclerosis, cerebellar disease, and, in its later stages, to Friedrich's disease. It is very slowly, if at all progressive, affects chiefly males, and is transmitted by healthy females. In the family described by them males only are affected. It corresponds to none of the commonly recognized types of familial affection, but the symptomatology so closely resembles that presented by the family recorded by Pelizaeus and Merzbacher that Batten and Wilkinson believe the disease to be of the same nature, although no pathologic examination has been made in any member of the family here described.

When the children were first seen Batten and Wilkinson were inclined to associate the condition with some congenital defect in the development of the cerebellum such as occurs in litters of cats and puppies, and have been recorded by Herringham, Andrewes, Risien, Russell and others, but after studying the pathologic anatomy as put forward in Merzbacher's paper, they have come to the conclusion that their cases probably belong to that group. Six males at least were affected in two generations. Those affected were either congenitally diseased or exhibited symptoms in the first months of life, the progress of the disease being very slow. They were mentally defective and ataxic, showed nystagmus, speech defect, and defective development, with weakness and spasticity of the lower limbs.

3. **Study of Posterior Longitudinal Bundle.**—The study by Muskens of the physiologic phenomena observed after lesions of different parts of the vestibulary system demonstrates that there is a far-reaching differentiation of function in the primary end-stations of the vestibulary nerve. Further, it also shows that the different strands of fibers which connect the vestibular nuclei with the various nuclei in the midbrain and with the region of the posterior commissure in a cerebropetal direction may be more accurately analyzed. The starting point of this analysis is the fact that an ascending degeneration of the crossed vestibulomesencephalic bundle, which forms the bulk of the mesial part of the posterior longitudinal bundle till near the nucleus of the posterior commissure, is always found associated with circus movements to the side of the intact posterior longitudinal bundle. The degeneration of an ascending tract lying immediately lateral to the crossed vestibulomesencephalic tract in the posterior longitudinal bundle formation appears to be equally associated with a circus movement (or rather conjugate deviation) to the side of the normal posterior longitudinal bundle. This tract is further shown to be a homolateral tract originating exclusively in the nucleus of Bechterew, at least in the oral parts of the vestibular region, and terminating in the region of the posterior commissural nucleus. This bundle is styled the homolateral vestibulomesencephalic fasciculus. Both the circus movements observed after lesion of the homolateral or crossed vestibulomesencephalic tracts are associated with conjugate deviation of the head and eyes to the side of the movement, or with loss of lateral deviation of the eyeballs to the opposite side.

From experimental data furnished by Muskens' investigation, it is seen that after a direct lesion in the region of the posterior commissure of the cat on one side, in which the resulting circus movements were directed to the side of the lesion, a descending tract degenerates which lies at the innermost part of the posterior longitudinal bundle of the same side. This tract probably originates in the posterior commissural nucleus. As it stops short in the medulla it is suggested that it may be termed the fasciculus commissuromedullaris. Like the circus movements the rolling movements may serve as a guide in working out the anatomophysiologic analysis of the vestibular complex and the posterior longitudinal bundle formation. After a direct lesion of the complicated nerve fibers, which help to form the vestibular root, a rolling movement toward the injured side is constantly observed, mostly associated with a skew deviation and conjugate rotation of the eyeballs around their anteroposterior axis.

In three cases of lesion of the descending branch of the nucleus vestibularis rolling movements toward the normal side were seen lasting over several days. Lesion of Deiters' nucleus proper was found in two cases associated with rolling movements, moderate in character, toward the side of the lesion. From this nucleus the degeneration spread upward along a tract which lies in the outermost part of the lateral horn of the posterior longitudinal bundle. A direct lesion of this ascending tract or connection is also associated with a tendency to roll toward the side of the lesion. This was demonstrated in five cases. The fibers of this tract appear to end mostly in the tegmentum, although some may be traced to the caudal part of the posterior commissure, in which the fibers appear to lose their medullary sheath; it is therefore suggested that it should be styled the tractus vestibulotegmentalis lateralis. Its origin is apparently in the medium-sized cells of Deiters' nucleus proper, its termination probably in the interstitial nucleus. A comparison of the cases in which the lesion is situated in the region of the posterior commissure leads Muskens to postulate in that region a center, probably the nucleus interstitialis, injury of which (or of its afferent tracts from other parts) in the cat is constantly followed by rolling movements to the normal side. If the descending connections of the vestibular structures which control the circus and rolling movements and those of the superimposed mesencephalic structures be compared, the conclusion seems warranted that the descending connections are far more important in the case of the rolling movements. Relatively few descending fibers which originate in the structures associated with circus movements pass beyond the sixth nucleus.

5. **Aphasia Due to Atrophy of Cerebral Convolutions.**—In the period between 1907 and 1909, Mingazzini's patient showed disturbances in his speech, which gradually increased and consisted in the use of unusual words in ordinary conversation (paraphasia and echolalia). He also experienced difficulty in understanding many questions. After two years (March, 1907, to August, 1909), the examination of the patient revealed true partial sensory aphasia (with automatic echolalia and perseveration), associated with paralexia and almost complete agraphia. In February, 1910, the sensory aphasia had become almost complete and some dysarthria was noticed in his repetition of words. The understanding of words was extremely limited; further, a condition of advanced dementia showed itself, accompanied by symptoms of agnosia. In October, 1910, the speech disturbances had become still more serious; the word deafness, the alexia and the agraphia were complete, while voluntary speech was almost entirely absent. Parallel with these progressive disturbances of speech a condition of mental weakness gradually developed, which at last became a true dementia and was attended with symptoms of agnostic apraxia, and psychial blindness. Two months later (four years after the beginning of the disease) the patient died. The post mortem revealed

severe atrophy of the prefrontal and temporal convolutions, the left side being the most affected, while the histologic examination showed severe alterations in the nerve-cells and medullary fibers of the convolutions belonging to the Broca region (*in sensu lato*) and to T, these changes being greatest on the left side.

6. **Satellite Cells in Mental Disease.**—The analysis by Orton of the relative numerical occurrence of satellite cells in ten cases, each of five psychoses, seems to him to warrant the conclusion that satellitosis cannot be considered in any sense indicative of the type of psychosis, although it has in this series appeared with more consistent intensity in the maniacal depressive cases and has been of very much less prominence in dementia praecox. The reaction elects the deeper cell layers both in regard to frequence of occurrence and degree of reaction. The cortices of the dome, precentral, postcentral and frontal, seems to show the reaction with greater intensity than do the temporal and occipital regions. Age at the time of death seems to play some part in the occurrence of severe reactions, but cannot be considered the only factor. The duration of the psychosis bears no demonstrable relation to satellitosis.

9. **Pinewood Sawdust as Surgical Dressing.**—Sawdust is used by Cathcart as a surgical dressing not only for operation wounds but also for septic cases of all sorts. It has also been much appreciated as a dressing for the shell wounds of the wounded German sailors in Edinburgh Castle, and it is valuable for cases of incontinence of urine. As to the wood, the sawdust from various kinds of pinewood has given good results. The softer kinds are the best, being more absorbent, while the harder kinds although less absorbent, have the advantage of containing more resinous material. Commercial hard woods like mahogany or oak should be excluded if pinewood can be obtained. A simple method of testing the absorbant property of a sample piece of planed wood is to draw a stroke across it with a pen full of ink. If the ink spreads laterally, and dries in quickly as it would on blotting paper, the fiber of the wood is good for surgical purposes. If the ink remains on the surface, as on writing paper, the absorbent power is deficient. Apart from the wood itself, however, a good deal of absorption will take place between the individual particles of the wood.

The method of preparation Cathcart has found useful is the following: Two large standard wire sieves are required —No. 8, that is, eight threads per inch, and No. 40, that is, forty threads per inch. In order to reject the coarse fragments the sawdust as obtained from the sawmill, is passed through No. 8, sieve and allowed to fall on to No. 40. It is then well shaken and rubbed on No. 40, and the very fine particles which pass through are discarded, because they would escape too readily from the prepared pads and cause an inconvenient dust. The sawdust which remains on No. 40 sieve is put into a box or sack and sent to the surgical nurse. The bags are made of butter muslin, and the sizes may be regulated according to requirement. The nurse fills the bag about two-thirds full with the sifted sawdust, and then closes it with colored thread. The filled bags or pads are sterilized by steam in the same manner as other dressings. After use the colored thread is withdrawn, the sawdust thrown away and the bag washed, boiled and dried for future use.

26. **Incontinence of Urine in Women.**—The operation Newman has performed successfully in a considerable number of cases during the last fifteen years is described as follows: The patient may be placed either in the lithotomy or in the elbow-knee position. The posterior wall of the vagina is fully depressed, so as to expose the anterior wall fully in view. The bladder is distended with 12 ounces of boric solution. A straight steel bougie No. 14, with a knob of the size and shape of a horse-bean half an inch from its point, is introduced into the bladder, at first fully and then partly withdrawn, so that the knob comes down to and locates the neck, and by elevating the handle of the bougie the knob is made to throw out the posterior wall of the bladder immediately above the sphincter, and so project it backward and downward. Three sutures, one anterior and two lateral, are now passed through the lips of the os, and the uterus is dragged downward so as to give a clear view of the anterior wall of the vagina.

A median vertical incision is now made from the uppermost point of the knob of the bougie downward over the knob and along the middle of the stem for a distance of 1½ to 2 inches. With blunt pointed scissors cutting on the flat the mucous membrane and muscular coat of the vagina are carefully separated on both sides of the median incision. Down to the submucous tissue of the bladder and urethra, without exposing the vesical mucous membrane itself. The vaginal mucous membrane is removed over a lozenge-shaped area, the center of which corresponds with the position of the most prominent part of the knob of the bougie; the upper angle is just over the point of the instrument. The lower angle corresponds with the stem, while the two other angles point outward one on either side. Incisions are now made to join the apices, and a lozenge-shaped portion of vaginal mucous membrane is removed, exposing a corresponding area of raw surface, the floor of which covers the neck of the bladder and the first half inch of the urethra. The next step of the operation consists in building up a dam to prevent the too easy escape of urine. The successful construction of this mechanical obstruction depends on heaping up a bank of mucous membrane on the vesical side of the septum and supporting it by tightening the structures behind—those on the vaginal side.

The sutures are chromic catgut and are introduced as follows: On the left lip of the wound the needle is passed from left to right; it enters immediately under the vaginal mucous membrane to come out one-eighth of an inch to the left side of the center line of the bougie; it is then carried over the rawed surface to one-eighth of an inch beyond the right side of the bougie, in which it penetrates the tissue, to be brought out on the right lip of the wound. Six sutures are passed in this way. The bougie is now withdrawn, and the sutures are tied, cut and buried. A second row of fine gut sutures is applied to unite the margins of the wound in the vaginal mucous membrane, and the operation is completed. No special after treatment is required, except that it is well to retain a small sized rubber catheter for the first six to eight days, and to cleanse gently the parts twice daily.

31. **Tetanus.**—Walther states that twenty cases of tetanus he has encountered among the wounded in his charge all came from a certain district along the Marne where tetanus has long been known to be frequent. It developed only among men wounded by shrapnel, and he thinks only when the exploding pieces hit the ground first or the explosion drove dirt from the ground into the wound. None of the bullet wounds was followed by tetanus. Hence he urges the necessity for prophylactic injection of antitetanus serum as a routine measure after a shrapnel injury. The Académie passed a resolution appealing to the authorities to have an ample supply of the serum on the firing line.

32. **Disturbances Liable to Follow Reduction of Obesity.**—Fiessinger thinks that there is much to sustain the assumption that the fat serves as a kind of filter to hold back certain toxic substances. When the fat is thrown off, these toxic substances make their presence felt, and the patient may develop rheumatism, sciatica, eczema, gout, interstitial *nephritis, or neurasthenia. "The connection between the loss of fat and the development of these troubles is conclusively* shown by their subsidence as the patient puts on a few pounds more of fat." His treatment of obesity is mainly dietetic, having the patient eat lightly seven times a day, so he never gets very hungry. He has had some disturbance like the above in fifteen of his 145 patients with obesity and heart disease, and in three the disturbance took the form of neurasthenia. In all the disturbances ceased as soon as the patients had gained 10 or 12 pounds again after they had previously thrown off from 22 to 45 pounds in a few months. As the fat recedes it seems to leave exposed the morbid taint which then exerts its injurious influence. The amount of reduction permitted should be carefully individualized and not be calculated for the height. See also Paris Letter, p. 1684.

40 Wounded Prisoners in Berlin. (Kriegsgefangenenlazarett Alexandrinenstrasse.) Brettner. (Die ersten Wochen kriegschirurgischer Tätigkeit.) W. Levy. (Schussverletzungen von Gehirnnerven.) *E. Froehlich.*

36. **Schizothymia.**—Kohnstamm's "schyzothymia" is best defined by an example of it. He cites, for instance, the paralysis suggested during hypnosis and persisting afterward. It is an interruption in the psychic continuity, and search for and removal of the cause in such a condition may realize a cure when otherwise the trouble would seem to be incurable cyclic insanity or the like. He compares it to a sand bank in a level desert of sand, and discusses it from various points of view.

39. **Dysentery.**—Göppert has had extensive experience with dysentery in children in the last few years and thinks that the lessons learned with them can apply also to adults, especially the necessity for feeding with mineral elements which have been lost in such amounts, also albumin in the most easily assimilated form and carbohydrates, but not too exclusively the latter. Whey and buttermilk supply the needed minerals for infants, and with this can be combined meat juice or soup. At first the fasting must be complete, but later hunger is liable to aggravate the course of the disease, but the digestive organs are left very sensitive so that motor insufficiency of the stomach is frequent. Fruit juices are also useful in the later course. The tenesmus and diarrhea are sometimes benefited by rectal injection of bolus alba, a handful to a liter of water, with a teaspoonful of salt. Its use internally is lauded by some, but Göppert thinks that the mild cases will get well without it and in the severest cases he says that it is impossible to influence with it the number of bowel movements or the general condition. Castor oil at first is the main reliance, and combination with opium may render good service. Biermer's mixture of krameria, cinnamon and logwood hastens the subsidence of the disease already on the wane, and he advocates it as a valuable aid even with this restriction.

41. **Supply of Food in Germany.**—Rubner says that Germany now leads all other European nations in the amount of meat consumed per capita, namely, 52.3 kilograms per year (1912). The figure for England was 47.6; for France, 33.6; for Austria, 29; Russia, 21.8, and Italy, 10.4. He states that Germany does not import meat and hence the supply will not be cut off by the war. "The only loss will be the eggs and poultry from Russia and sea fish, but these can probably be obtained from neutral countries in sufficient amounts." Only about three-fourths of the wheat used in Germany is raised there, but there is an overabundance of rye, and this will more than compensate the loss of wheat and of rice. Only 28 per cent. of the potato crop has been used for the table; the distillers took 4.6 per cent., the starch factories nearly as much, and nearly 50 per cent. was used for fodder. A large proportion of the potatoes usually rot before spring, and here a change must be made to prevent this waste. Desiccated potatoes can be used to advantage in soups, purées, etc.

Germany has been in the habit of exporting its rye and importing cheaper fodder from Russia. The loss of this 3,500,000 tons of cheap fodder can be made up from the surplus of other grains. Parliament has regulated the matter so there can be no wholesale slaughtering of cattle for pecuniary reasons. He reiterates that the stock of cows must be maintained at all hazards, and that the supply of milk can be rendered more plentiful by a little more economy in consumption of butter. He figures that if each person would stint himself just a little (1 gm.) butter each day this would be equivalent to releasing the milk of 300,000 cows for other purposes. He continues, "When the man of the house is away, the family table is usually much simpler. It is of the greatest importance that the army is now living in and off the enemy's country and that many accumulated stores of provisions have fallen into our hands."

43. **Dysentery.**—Grober states: "In the present epidemic there have been 19 deaths in 400 cases, and there were 23 house infections. The bacilli alone do not cause dysentery; there are probably many healthy carriers by this time. Some

error in diet throws down the barriers by inducing irritation in the bowel. The first symptoms generally appear about three or four hours after ingesting too young beer, soggy bread or unripe fruit or drinking much contaminated water. They range from slight discomfort to the severest toxemic conditions in a few hours but intense tenesmus and blood in the stools are the rule. The pains are sometimes ascribed to the stomach; the transverse colon is probably responsible for this." He has one patient who for six weeks has had fifteen or twenty thin, bloody stools daily, but as long as the heart keeps strong, hope should not be given up. Convalescence is very slow and for weeks the patients seem apathetic and dull. Even in the mildest cases, recovery takes about two weeks, and relapses are not uncommon. In treatment, serotherapy is the main reliance. A dose of castor oil is given next, but he never saw much benefit from tannin preparations. Light red wine, boiled and with cinnamon, seemed to give great subjective relief. Tincture of opium is reliable but such large doses are necessary that the effect on the heart may be detrimental. In many severe cases the distress was so extreme that morphin had to be given. Singultus was hard to control; sometimes it yielded to a narcotic after scraps of ice with a few drops of some fruit juice had been dissolved in the mouth. Opium suppositories occasionally, but not always, relieved the tenesmus; bolus alba did not seem to display any efficacy in the severer cases in which alone it was used. His experience confirms the necessity for heart stimulants if the circulation weakens. He did not try ipecac. Moist heat to the abdomen gave great relief as a rule. The patients were kept on gruel, tea, cocoa and light red wine as long as the stools contained blood and mucus, but henceforth he is going to try a little more nourishing food. (The *Berlin. klin. Wchnschr.* of October 12, reports 924 cases of dysentery at over forty scattered points in Germany, including Cologne, Breslau, Kattowitz and Kreuzburg, mostly among the prisoners.)

Prophylactic measures are simple, refraining from touching the face with the hands (smoking) and cleanliness in eating, but above all refraining from errors in diet. "Medical men in the tropics have found it an aid in prevention to take five drops of dilute hydrochloric acid in some beverage at each of the principal meals. The dysentery bacillus is extremely susceptible to hydrochloric acid." "Transmission of the disease by flies has been abundantly demonstrated anew in the present epidemic, and it is impossible to overestimate this danger."

44. **Venereal Disease in Wartime.**—Blaschko remarks that down into the eighteenth century an army of prostitutes regularly accompanied every army in active service, sometimes outnumbering the troops. "But this army of female camp-followers," he continues, "did not become a hygienic danger until at the end of the sixteenth century syphilis swooped down on the troops and has been at home throughout Europe ever since. The introduction of the system of compulsory military service altered all this, but even Napoleon was unable to prevent hordes of female camp-followers from accompanying his army in the campaign into Russia, and in the recent Russo-Japanese War the Russians, especially the officers, were accompanied by some."

"Although the present war is far graver than any of the wars in previous centuries, yet we must accept the possibility of a great increase in venereal diseases. The men left in charge of a conquered city are particularly exposed to this danger. In some the brothels have been closed, but in other cities, where people still believe in the hygienic efficacy of these institutions, they are flourishing more than ever. But conditions are not much safer even where there are no brothels. I have seen here in Berlin a number of cases of recently acquired gonorrhea and syphilis among the troops and the number of reservists who were found healthy on joining the colors and who already have been sent back from the front for treatment of gonorrhea acquired since is larger than is generally supposed."

"During the last half of the Franco-Prussian War, venereal diseases formed 9 per cent. of all the morbidity. It is self-evident that men with fresh gonorrhea are unable to go on marching or fighting."

"In peace, regulation of prostitution does not accomplish much, but the strict measures that can be enforced under exceptional conditions, as during a campaign, may be of the greatest utility. Absolute prohibition of public dances, and the early or total closing of saloons will help, and extreme care must be taken to weed out any loose women that may attach themselves to the army in the guise of nurses, etc. This sifting out must be done chiefly in the base stations. The hygienist accompanying the corps must have previously informed himself as to the conditions regarding prostitution in each district the corps enters."

"Many physicians regard it as impossible to prohibit entirely to the troops all intercourse with prostitutes. But this is absolutely false, according to my opinion" . . . "Keeping secret a beginning venereal disease justifies punishment." Blaschko remarks in conclusion that the many women deprived of their livelihood now by the shutting down of factories, etc., present a particularly serious danger, and it behooves the authorities to provide employment for them in some way or at least food and shelter. Well-to-do women who serve gratuitously from patriotic motives in preparing articles to be sent to the soldiers, etc., had better ponder whether it would not be better to set some of the unemployed at the task and pay them for it. He protests against the exclusion of cases of venereal disease from the hospitals, to make room for wounded soldiers as has been done in some quarters, calling it a very short-sighted policy which will bring retribution later.

52. **Care of the Feet.**—This is only one of the points touched on in Pinkus' article on the importance of skin lesions and disease among the troops. He says "Every soldier is trained in the care of his feet, from the very beginning of his military service. The troops are trained to stand the longest marches by combating sweating of the feet, by the use of suitable shoes and inner covering for the feet, and by systematic exercise of the muscles during the exacting drill. The foot-cloths used instead of stockings are of great service in protecting the feet against getting sore. They are easily changed, easily cleansed, as they dry rapidly after washing, and if they shrink during washing this does no harm. Washing and drying are much harder with woolen socks, and they are liable to shrink and squeeze the toes, while the spots worn thin or in holes come always at the same points on the foot, and where there is greatest danger of abrasion. With the foot-cloth, on the other hand, fresh parts each time can be drawn over the heel, etc., thus protecting them against injury. Those unaccustomed to these foot-cloths may not like them, and for such the next best is to draw on a second sock over the first, both amply large. The woolen double sock forms an extraordinarily elastic foundation for the foot, keeps it

warm, and protects it against wet and against pressure from the stiff and shrinking leather when it gets wet. The double socks also absorb perspiration well and enable the socks to be changed about, putting on first one and then the other." He warns that sweat and dirt invite eczema in folds in the skin, and also annoying and tenacious *mycosis*, especially around the anus and genitals—all of which can be warded off by systematic cleanliness, especially sponging off with alcohol.

53. **Infectious Diseases Liable to be Encountered During the War.**—Eichhorst says that no means of protection against exanthematous typhus, "war typhus," like vaccination against small-pox, is known, and it is liable to be brought into Germany by Russian prisoners of war. Bacteriologic differentiation of it is not on a sure footing as yet. "With salvarsan we can cope with relapsing fever; plague is not near enough to cause alarm, and cholera can be kept out by scrupulous hygiene, but tropical dysentery is liable to be encountered as troops from Africa and India are fighting with the Allies."

54. **Foot Swellings in Soldiers.**—Müller remarks that the Roentgen rays have explained this trouble, first described in the middle of the last century as peculiar to soldiers obliged to march long distances. The rays revealed it to be a fracture or periostitis of a metatarsal bone. About 22.5 per thousand of the troops develop this trouble each year, with or without contributing trauma. It generally can be cured in fifteen to thirty days; only about 0.5 per thousand have any disturbance left, from pains or too exuberant callus. It appears as a white, doughy swelling on the dorsum of the foot. If the tenderness is limited to one point, the trouble is probably a fracture. In a few days walking becomes impossible. By strapping the foot with plaster the man can continue to use it, applying massage, warm baths and moist heat, renewing the plaster each time. If he can be kept in bed, stasis hyperemia and superheated air are effectual; but a plaster cast or extension may be necessary if there is dislocation of the fractured stumps. The adhesive plaster is applied with the foot standing flat on a stool, the heel at the edge. The strip of plaster is applied to the back of the foot, at the tubercle of the fifth metatarsal bone, drawn tight straight down over the outer edge of the foot and around under the sole while, with the other hand, distally, the metatarsal bones are squeezed together and their dorsal convex arch exaggerated. The plaster is then brought up on the dorsum above the first cuneiform bone. The plaster thus serves to hold the middle part of the foot firm and acts as a splint for the broken bone while strengthening the arch. Other conditions that may be confounded with it are acute articular rheumatism, flat-foot and inflammation in the joints, cellular tissue, tendon sheaths, or bursae.

68 Return to the Front of the Slightly Wounded. (Rückkehr Leichtverwundeter an die *Front*.) G. Herhold.

59. **Roentgen Treatment of Surgical Affections.**—Oehler calls attention to the fine results he has obtained with deep Roentgen treatment of accessible surgical affections, even when there was mixed infection. Subsidence of pain and improvement of function were particularly evident with incipient processes in the knee and head of the humerus, but it was difficult to influence the hip joint. The method is peculiarly advantageous for tuberculous lymph-glands in the neck, spina ventosa, and tuberculous processes in the smaller bones and joints, in the ribs, sternoclavicular joint, and tendon sheaths. Lymphoid tissue is peculiarly susceptible to Roentgen treatment, and "scrofulous" glands in particular, but goiter does not seem to respond well. In the exceptional cases in which benefit was observed, it was only transient. In one case Basedow symptoms came on for the first time after the third exposure of the thyroid.

65. **Tetanus.**—Kreuter says that reports from the various hospitals harboring the wounded from the front almost without exception mention the development of tetanus in more or less numerous cases. Injuries from shrapnel, from being run over and from being kicked by a horse expose to special danger of tetanus. "The tetanus bacillus," he continues, "does not induce suppuration so that the aspect of the wound does not even hint at its presence." "Disturbance in swallowing, with no cause for it evident in the throat, is characteristic and trismus may be early apparent." In the hospital in his charge (Erlangen) he has had a number of cases of local tetanus, the cramps restricted to the part directly injured. The mortality averaged 80 or 90 per cent. when the incubation period was less than eight or ten days; immediate amputation of the injured limb failed to arrest the tetanus in the two cases in which this was done. He warns that we must not look for improvement after injection of antitetanus serum; all it can do is to cut off the further supply of the toxin to the nervous system. Other measures must be called on to arrest the convulsions, as death comes usually from exhaustion or suffocation. He gives morphin every two or three hours, with a rectal injection of chloral at night. Antitoxin serum, according to Permin's statistics, has reduced the mortality from 95 to 73 per cent. with incubation of less than ten days, and from 70 to 40 per cent. with longer incubation. He gave magnesium sulphate according to Meltzer and Auer's technic and found that it modified the convulsions almost instantaneously but caused such serious disturbance in breathing that artificial respiration had to be kept up for hours. To combat this, he suggests that Kocher's method of tracheotomy and insufflation of oxygen might be tried or Arnd's method of rinsing out the lumbar sac. Baccelli's phenol method has no curative action and as a sedative it is far surpassed by other drugs. The brilliant statistics in regard to its use that come from Italy are explained by the mild course of tetanus in that country. The mortality is said to have averaged only 20 per cent. even before tetanus serum was introduced.

66. **Cutting Both Phrenic Nerves in Tetanus.**—Jehn reports from Sauerbruch's clinic at Zurich a case of extremely severe tetanus in a boy of 8 who was suffocating from recurring spasms of the respiratory apparatus, each lasting three or four minutes with cyanosis and unconsciousness. The rigid thorax and spasm of the diaphragm rendered artificial respiration impossible. After the third spasm of the kind Sauerbruch severed the phrenic nerve on each side through an incision along the posterior margin of the sternocleidomastoid, under ether. The type of breathing altered at once and artificial respiration became possible. The boy had thirty-five severe convulsions afterward, but with oxygen, artificial respiration and a temporary gastrostomy he was tided along to final recovery. The boy shows no ill effects now, four months later; the diaphragm rises and falls mechanically with the breathing. Expectoration proceeds even better than under normal conditions.

67. **Bolus Alba in Dysentery and Cholera.**—Stumpf reiterates his advocacy of bolus alba—kaolin—as an effectual and harmless method of treating intestinal diarrheic troubles. It acts mechanically, burying the germs under the insoluble powder and protecting the inflamed mucosa. His method has been repeatedly referred to in The Journal. He says that the authorities have laid in large supplies of bolus alba to combat dysentery and cholera, and adds, "If ever a method

of treatment had a scientific basis, it is this one. I got my enthusiasm for it from the microscopic findings." A smaller dose by the mouth than the suspension of 300 gm. is inadequate.

80 Undescribed Fungus Found in Pus in Chronic Upper Jaw Process. C. L. Rusca.

74. **Laryngectomy for Cancer.**—Bevacqua adds two new cases to the four previously published in which the entire larynx was removed by Durante's technic, and ten other cases have also been published by others. These bring to ninety-nine the number of cases of total laryngectomy on record in Italy. Bevacqua's first patient survived the operation for nearly two years before succumbing to metastasis. The second patient died of pneumonia ten days after the operation. Durante's technic thus does not guarantee against postoperative pneumonia but wards it off better than other methods, as a rule. The flap starting at the angle of the jaw on each side, skirts the anterior margin of the sternocleidomastoid and reaches down to 3 cm. from the upper end of the manubrium. This flap is turned back on a level with the hyoid bone. The cannula is introduced into the trachea after incising the thyrohyoid membrane, and then the larynx is excised from above down to the second ring of the trachea. The flap is then turned back and sutured to the edges of the mucosa of the pharynx and esophagus so that the lower point of the flap rests on the stump of the trachea and is sutured here. Of all the raw surfaces nothing is left exposed but two strips at the side which are packed with gauze. The patient can swallow by the end of the first day.

75. **Papilloma in Kidney Pelvis.**—In the first of the two cases reported the kidney was removed on account of the pains, hematuria and other findings indicating a tumor in the kidney pelvis. After three years of health, symptoms developed suggesting a similar growth in the remaining kidney. This patient was a man of 40. The other was an elderly woman with hydronephrosis and papillomatous growths in the kidney pelvis. The shell of kidney left was cleared out and sutured to the skin and the patient recovered.

76. **Operative Treatment of Exophthalmic Goiter.**—Scalone reviews the literature of the last three years on this subject, his conclusions being all in favor of operative measures in suitable cases, and he urges practitioners to insist on it before irreparable lesions become installed.

77. **Cholecystectomy for Infected Gall-Bladder without Stone.**—The two cases reported by Cignozzi confirm the harmlessness and various advantages of removing the gallbladder when it is the seat of chronic or subacute inflammation. One patient had suffered from recurring colic for three years, the other for six weeks.

78. **Effect of Conservative Operations on the Kidneys.**—Poggiolini gives illustrations of the findings in the kidneys of twenty rabbits and a number of controls after a kidney had been subjected to various experiences resembling those commonly encountered in clinical work.

79. **Hot Air Treatment of Granulating Surfaces.**—Stoppato noticed that after a burn the parts left exposed to the air healed more rapidly than regions dressed with various salves, etc., or merely shut off from the air. This suggested that keeping the surface dry would be beneficial and to promote this he applies a jet of hot air. A number of illustrations are shown of the way in which rebellious burns promptly healed under fifteen to thirty applications of the jet of hot air. Heat evidently stimulates repair of epithelium by the hyperemia which it induces.

81 *Conglutination by Karvonen's Technic as Substitute for the Wassermann Reaction. W. Leschly and H. Boas.
82 *Tumor of the Acoustic Nerve; Six Operative Cases. A. Wimmer. Commenced in No. 38.

81. **Conglutination Test Not as Reliable as Wassermann's.**—Leschly and Boas applied Karvonen's technic in 456 cases, including 278 known syphilitics, but found the results less instructive than the Wassermann, positive results being obtained in a number of non-syphilitics, and vice versa.

82. **Tumors in Acoustic Nerve.**—In Wimmer's six cases the outcome of the operations was not very encouraging. The first patient, a woman of 35, died from infection of the wound. She had been deaf for several years on the side of the tumor before other signs of a brain lesion became apparent. No such "free interval" was apparent in the second case, a man of 51, who for eighteen months had had headache, vertigo, vomiting and other symptoms of a brain tumor. Deafness on that side developed suddenly after a few months. He died about six hours after removal of the large sarcoma. In the third case there was a free interval of seven years between the initial deafness and the other symptoms of a brain tumor. Intervals of blindness on this side were the next symptoms. He died the third day after the sarcoma had been shelled out. The fourth patient referred all his symptoms to the effects of a lighting stroke in 1908, which had left him paralyzed and deaf on one side, but this could not actually have been the case as it seems improbable that a gliosarcoma could have developed so rapidly in consequence of the man's being struck by lightning. The tumor must have been growing at the time and the lightning stroke induced hyperemia in it and an apoplectic attack. This subsided as the extravasated blood was absorbed, leaving the symptoms of merely the brain tumor. He died suddenly five hours after the operation. The fifth patient was a woman of 55. Four years before she noticed that she had suddenly become deaf in the right ear. During the following years disturbances in gait gradually developed and finally vision became impaired and then intense pain developed suddenly in the left side of the face. The left side of the tongue felt as if she had burnt it and her speech was thick, but there was no headache, no vomiting or psychic torpor as in some of the above cases. Other signs confirmed the diagnosis of a tumor involving the acoustic nerve, and it was successfully removed. In a sixth case intervention had to be restricted to a decompressive trephining, leaving a safety-valve opening which was of great benefit.

88 Tests for Estimation of Functional Capacity of Lacrimal Apparatus. (Fluorescein og argyrol til undersøkelse av taareledningen.) H. Lystad.

85. **Adhesive Pericarditis.**—Holst found evidences of adhesions in the pericardium in about 4 per cent. of a series of 1,586 necropsies. In 30 of the 61 cases there was no valvular defect. In the other 31 cases there was tuberculosis in 10, chronic nephritis in 6 and only 3 cases of "pure" adhesive pericarditis. The details of 2 in this last group are reported in full. The patients were men of 22 and 30. The younger man developed pericarditis after diphtheria at 14 and the symptoms from adhesion gradually became manifest in the course of eight years. The other patient had always been healthy. Both were treated by resection of three ribs over the apex region to reduce the resistance opposed by the rigid wall to which the pericardium had become attached. The effect was strikingly good in the first case and the young man was able to resume his work as a clerk. Later some ascites and edema returned, and the liver enlarged again, but the general condition has kept good during the five years to date. Before the cardiolysis there had been cyanosis, difficulty in breathing and so much dropsy that the patient was confined to bed at times. The heart was not enlarged and the sounds were pure. No apex beat was perceptible and the fourth and fifth ribs and interspaces were dragged inward at each systole. There was no albuminuria, no paradoxic pulse and no diastolic collapse of the veins. The operation gave immediate relief.

Conditions were about the same in the other case except that the apex beat was perceptible and there was diastolic vein collapse. Roentgenoscopy showed an irregular shadow supposed to be a strip of calcification, as also shadows suggesting adhesions running from the heart to the right diaphragm. Gradual improvement followed the operation, but the ascites returned later and it has had to be tapped several times during the nearly two years since, so that the operation was but a dubious success.

He discusses the differentiating points, with curves from various cases, and emphasizes that cardiolysis acts exclusively on the symptoms which result from the parts having been connected by adhesions. Complicating "iced peritonitis" or stasis peritonitis, or cirrhosis of the liver, or myocarditis may modify the clinical picture, but the symptoms from these are not influenced by any operation on the chest wall.

86. **Homotransplantation of Kidneys.**—Ingebrigtsen states that some of his experiments on dogs and cats proved technically successful but still the transplanted kidney lost its vitality. He thinks that there is little hope of clinical transplantation of these organs, on account of the individual differences between the donor and the recipient. This will not be possible until means are discovered to estimate beforehand the serologic and biologic properties of each party and thus select those that fit together.

87. **Diabetes and Pregnancy.**—Geelmuyden comments on the connection between the functioning of the female internal genital organs and carbohydrate metabolism, saying that glycosuria develops regularly in about 10 or 12 per cent. of all pregnancies. Some have encountered it in 40 per cent. Usually lactose is the sugar in the urine in this benign pregnancy glycosuria, but it may be grape sugar or both. The proportion of sugar in the urine may be so large as to suggest severe diabetes with acidosis. Differential points are its onset first during the pregnancy, its independence of carbohydrates in the diet, and the absence of polyuria and excessive thirst. He has known instances of these latter symptoms, polyuria, thirst and pruritus occurring with unmistakable pregnancy glycosuria. Knowledge that the urine before the pregnancy was free from sugar is a great help. Also the findings that the acidosis does not fluctuate with the intake of carbohydrates. Normal or subnormal proportion of sugar in the blood sustains the assumption of the benign form. In case actual diabetes is suspected, the diet must be regulated very cautiously as there seems to be a special liability to acidosis and coma in pregnant women. Carbohydrates must be cut down very cautiously, taking a couple of weeks for it, and always under constant control of the urine. Bicarbonate may also be required and "oatmeal cures."

Opinions are divided as to the necessity for terminating the pregnancy; cases are on record in which evacuation of the uterus arrested incipient coma and undoubtedly saved the woman. Waiting to save also the child, has often resulted in the loss of both lives. Even in the cases of apparently mild diabetes, the outcome for both may be disastrous. If the woman was under observation for some time before the pregnancy, it is usually possible to tell whether it now is of a progressive or stationary type; if not, study of the case over a sufficient period may throw light on this. It is a question of general internal medicine and not gynecologic alone, and strict individualization is indispensable. If the pregnancy is to be terminated, we must bear in mind that diabetics do not stand well general anesthesia and cutting operations. Geelmuyden has known chloroform to bring on coma in diabetics. He thinks it is not always necessary to forbid pregnancy for diabetics. They must be warned, however, of the danger they run. It is more threatening the younger the patient, so that quite young women with diabetes should be emphatically warned against possible conception. His long bibliography on the subject does not include any American names.

89 *Typhoid Bacilli in the Blood Revealed by Microscope. (Den direkte, mikroscopiske Paavisning af Tyfusbacillen i Patientens Blod og denne Undersøgelses Betydning for Diagnose og Behandling.) V. A. Wille.

90 *Cancer Disappears after Intercurrent Erysipelas; Three Cases. Strandgaard.

89. **Typhoid Bacilli in the Blood Under the Microscope.**—Wille writes from Java that the microscope revealed the typhoid bacilli in the blood at every one of his 160 examinations in sixteen cases. After an error in the diet the number of bacilli in the fields was materially increased, even before there was any rise in temperature. As soon as the error in diet was corrected, the number of bacilli dropped off. In this way it was learned that fresh milk was not a suitable food for typhoid patients. They thrived much better on unsweetened condensed milk. The microscope was also a guide to know how much milk could be assimilated by the different patients. When the individual limit was overstepped, the bacilli in the field ran up from 30 to 250 as also after large doses of drugs. One of the patients was thus proved unable to eat meat; far into convalescence, any meat or fish at once sent up the number of bacilli. Wille's experience further demonstrated that the finding of typhoid bacilli in the blood does not necessarily imply existing typhoid; they may be relics of typhoid infection years before. In nearly all his cases bacilli were still to be found in the blood months after recovery from the disease. In a later series he examined the blood of fifty healthy persons in Denmark and found scanty typhoid bacilli in the blood in 50 per cent. while the proportion had been over 78 per cent. in sixty-six healthy Javanese examined and the bacilli were much more numerous. He believes that a person can have typhoid bacilli abounding in his blood without his being what is called a bacilli-carrier. Burri's technic was found practical and reliable for showing up typhoid bacilli under the microscope.

90. **Cancer and Erysipelas.**—Strandgaard reports three new cases in which severe wandering erysipelas developed in three elderly persons with a palpable cancer in the colon or breast, primary or a recurrence. The tumors rapidly subsided during and after the erysipelas, and striking improvement in the general health followed. The mammary cancer retrogressed completely. The intestinal cancers likewise retrogressed but one soon returned and proved fatal. In the other case the bladder became infected and the man died. The infection probably was from the breaking-up cancer.

THE WET NURSE IN HOSPITAL PRACTICE*

FRANK SPOONER CHURCHILL, M.D.
Attending Physician, Children's Memorial Hospital
CHICAGO

The high death-rate during the first year of human life is a phenomenon now attracting the attention of all civilized peoples. It is a condition peculiar to no one nationality, city or community, but prevails everywhere the world over. Broadly speaking, this mortality is due to ignorance and poverty. Hence most of these deaths occur in the homes of the poor and ignorant, both in cities and rural districts. A large proportion, however, is contributed by infant asylums, institutions and hospitals. It is with the high death-rate in the last named institution—babies' hospitals—together with measures taken to combat it, that this paper deals.

It is somewhat startling to note the high death-rate which prevails in even our best infant hospitals. It ranges from 30 to 40 per cent. in different institutions in different years. The reason is not far to seek; the babies are brought to the hospital invariably in a state of chronic malnutrition, often suffering from some acute disease. Their resisting power is low. Their progress is slow, necessitating a long stay in the hospital, thereby exposing them to the danger of communicable disease, of the respiratory tract in winter, and of the intestinal tract in summer. All of these factors result in a high death-rate.

Modern methods of substitute feeding, so successful in private practice, are not attended with the same beneficial results when applied in hospital practice. One baby dying out of every three admitted is hardly a satisfactory record. It is undoubtedly this unsatisfactory result with substitute feeding which is giving rise to the tendency to revert to the more widespread use of human milk in the management of these hospital cases. The superiority of breast milk to all other foods for babies in health is universally acknowledged. It would seem as if its use among sick babies also ought to be attended with results better than those attained by any other food. In accordance with this view the staff of the Children's Memorial Hospital have, for a period of five years, resorted to the use of human milk in their management of the hospital infants. During the first two years of this period, 1909-1910, breast milk was used irregularly; during the last three years, 1911, 1912 and 1913, more regularly and constantly.

It is to a discussion of the methods used and the results there obtained that I now invite attention.

METHODS AT CHILDREN'S MEMORIAL HOSPITAL

We have kept on hand two or three wet-nurses at a time. They come from the Salvation Army headquarters. Each nurse brings her own baby; both mother and baby are examined before engagement, the examination of the mother including a Wassermann test. The nurse is paid $30 per month, room and board, and in addition to her duties as foster mother, does general work about the hospital.

The mother nurses her own baby every four hours, usually on one breast. The other breast is pumped the alternate four hours, the mammae thus being stimulated to activity every two hours. The milk is fed by bottle to the ward babies, none of the latter being put to the breast for fear of infecting the woman, for example, with a latent syphilis. This method has the further advantage of allowing us to feed definite amounts of breast milk to a given baby. Except for the prematures, few of the babies receive exclusively breast milk, but are on "mixed" feeding—part human milk, part bovine milk. The feedings of the latter are gradually increased as the infant improves preparatory to sending it home on a simple milk formula. As a rule the milk from all nurses is mixed and fed thus to the ward babies; in some cases, however, babies with a particularly weak digestion receive the milk from a single nurse, which milk analysis has shown to be a "poor" milk; or such a baby is given the "foremilk." In several instances one of these proceedings has seemed to improve a faulty digestion.

The amount of breast milk furnished by each nurse of course varies in the different women. During the first few days they each average 8 to 10 ounces daily in addition to that given their own babies. This increases quite rapidly under the use of proper hygiene and the two hourly stimulation of the breasts, until the maximum is reached, this maximum ranging from 16 to 60 ounces per day. We do not consider a wet-nurse a good one unless she furnishes at least a pint of milk daily for the ward babies.

The average "life" of a wet-nurse has been nine to ten months; the maximum has been thirteen months. They come to us when their own babies are about a month old.

It is evident that, by the method thus briefly outlined, many babies can receive a certain amount of breast milk daily, especially as most of these infants, below par, with a correspondingly weak digestive capacity, can take only small amounts at a feeding. We averaged, for example, during the year 1913, 58 ounces of breast milk per day; with feedings averaging in amounts 2 to 3 ounces, twenty to thirty feedings of breast milk are available, enabling us to give three to four feedings to each one of eight or ten babies daily.

---

* Chairman's address, read before the Section on Diseases of Children at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

RESULTS

What results have been obtained by this method of treatment of our hospital infants? Have those fed on breast milk done better than those fed on some modification of cow's milk? Has the infant mortality of the hospital decreased since the systematic use of breast milk was begun? To determine these points, I have studied the records of a large number of babies treated at the hospital during the last three years. The records have been divided into two parts, the first consisting of all babies fed on breast milk either exclusively or in combination with some modification of cow's milk; the second, of all babies fed on some modification of cow's milk alone.

The total number of cases studied is 715, of which 165 fall into the breast-fed and 550 into the cow's milk group. They range in age from 1 day to 1 year, in weight from 5 to 20 pounds. They include the types of cases usually seen in an infants' hospital, of varying degrees of severity, from mild cases of disturbed feeding to severe types of ileocolitis and severe degrees of "intoxication." The mortality among the 715 cases as a whole is 36.7 per cent.; among the breast-fed babies, Group 1, it is 36.3 per cent., among the cow's milk fed babies, Group 2, it is 36.9 per cent. Thus the mortality in both groups is practically the same.

MORTALITY IN GROUPS 1 AND 2

All members of Group 1 received as part of their diet a food universally acknowledged to be the best for infants. The members of Group 2, on the contrary, received no such food and were, to this extent, handicapped in the race for life. Yet even with this handicap in a matter of such vital importance, the group loses no more cases in proportion than does Group 1. What is the reason? Obviously the members of the second group must possess some advantage of their own to offset that enjoyed by Group 1 in the matter of diet. This advantage must consist either in some superiority of general management or in some condition of physique indicative of greater vigor and vitality.

The general management was the same in both groups: the cow's milk group did not enjoy the advantage, for example, of living in private homes. All the members of both groups lived (or died) in the same hospital, attended by the same physicians and nurses, exposed to the same atmosphere, to the same communicable diseases; in all respects the general environment was the same for both groups. Any advantage enjoyed by Group 2 could not, therefore, consist in its management. It must consist rather in some physical condition of members of the group, by virtue of which they possessed greater resisting power to disease.

The best index to the vigor and resisting power of an infant is his weight at a given age. In order to compare the vigor and physical condition of the two groups, therefore, the average weight and age on admission were determined, with the following results:

Average weight of 165 infants in Group 1 was 7.6 pounds
Average weight of 503 infants in Group 2 was 9.3 pounds
Average age of 165 infants in Group 1 was 3.8 months
Average age of 503 infants in Group 2 was 5.3 months

Thus it appears that the members of Group 2 were, on an average, 1¾ pounds heavier and 1½ months older, than those of Group 1; and in this superiority of weight and age lies the advantage possessed by the former group, and the explanation of its relatively low mortality.

We are discussing, however, not primarily the effect of physique and natural vigor on infant mortality, but the effect of one kind of feeding on this mortality as compared with another kind.

Obviously the comparative value of two methods of feeding cannot be gauged by applying these two methods to groups of infants with different degrees of vigor. Such values can be determined only by carrying out the two methods on groups of infants of equal vigor and living under the same conditions of general hygiene. In order to do this in the present study, the following plan was pursued.

It was observed that the weight of the great majority of the infants in Group 1 fell within the limits of 6 and 9 pounds. From Group 2 were now selected all the cases ranging in weight between 6 and 9 pounds, and the average weight determined. They constitute Group 2a. They numbered 234, of whom 131 recovered and 103 died. They averaged in weight 7.7 pounds, in age 3.9 months, the averages, it will be noted, of Group 1. To test the relative influence of breast milk and cow's milk in their effect on mortality, we now compared the death-rate of Group 1 with the death-rate of Group 2a, both groups consisting of babies approximately equal in vigor and resisting power but receiving different foods. The mortality rate of Group 2a was determined and found to be 44 per cent.[1] as compared with 36 per cent. in Group 1.

Thus of two groups of infants equal in weight and age, living under identically the same hygienic conditions, the one group receiving *some* breast milk, the second group *none*, a larger proportion of those receiving breast milk survive. It seems reasonable to attribute the lower mortality of this group to the breast milk received.

But while these figures are in favor of breast milk, as was to be expected, the difference is by no means striking, only 8 per cent., and the mortality of the favored group still remains high. There are two possible explanations for this continued high death-rate: the desperate nature of the cases involved; indiscriminate use of a limited supply of breast milk.

The serious condition of hospital infants on admission has already been mentioned. Many come in practically moribund, improve under no treatment at present known to us, sink steadily and die. Such are many of the cases of "intoxication" with or without some complication, for example, bronchopneumonia. The manipulation of proteins yesterday, of fats to-day, of sugar and salts to-morrow, does not save these babies. At present they are out of our reach. We have much yet to learn as to their proper management. To some of these we have fed breast milk whole, skimmed, diluted; to some, modified cow's milk, using the term "modified" in its proper comprehensive sense to include any modification or manipulation of cow's milk, whether it be a simple dilution of whole milk, or the complicated *"Eiweissmilch"* with or without the addition of maltose. It is not at all improbable that breast milk is not the proper food for many of these babies; it is entirely within reason to believe that some combination of water, fat, protein, sugar and salts other than that present in any breast milk will be found to be better adapted to the conditions existing in these infants. At present, however, we must frankly accept and face our ignorance concerning them. In spite of human endeavor they raise the infantile death-rate.

---

[1] Recoveries 131; deaths 103.

Consideration of the second point, the proper distribution of a limited supply of breast milk, presents a more hopeful outlook. It is generally believed that the giving of one or two feedings of breast milk to a bottle-baby during the twenty-four hours is beneficial and enables that baby to digest and assimilate higher percentages of the ingredients of cow's milk than he could do without this human milk. As far as healthy infants are concerned, this is undoubtedly true. To what extent this applies to sick infants, I have sought to learn from further study of the present cases.

The records of the breast-fed group have now been regrouped into three subdivisions, A, B and C: those receiving exclusively breast milk, those receiving at least half breast milk for a limited critical period, those receiving less than half breast milk for such a period. The mortality-rate has been estimated in each of these subdivisions, giving the following results:

A. Of 17 infants exclusively on breast milk, 10 died; mortality, 59 per cent.

B. Of 62 infants on at least half breast milk, 2 died; mortality, 3 per cent.

C. Of 58 infants on less than half breast milk, 29 died; mortality, 50 per cent.

Division A consists of desperate cases. We assumed, rightly or wrongly, that breast milk would give them the best chance for life; hence their diets consisted exclusively of breast milk. How unsuccessful we were the high mortality shows.

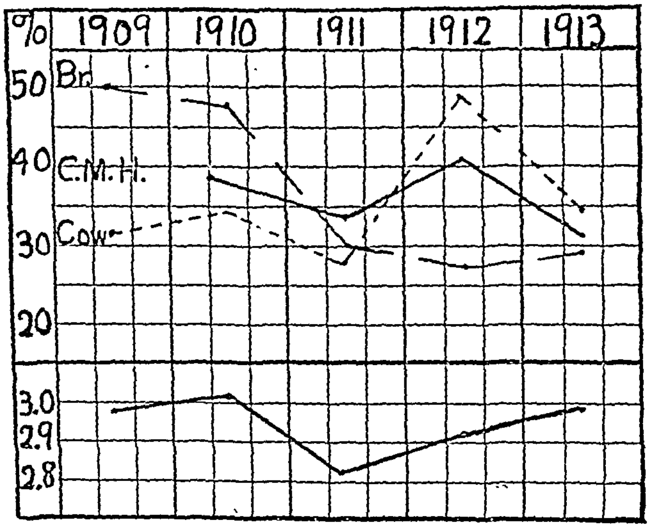

Chart showing infant mortality rates for the years 1909 to 1913, inclusive: Above, the solid black line shows the general hospital infant mortality; the broken line the rate among breast-fed infants; the dash line the rate among infants fed on cow's milk.

Below, the curve shows the deaths in the city of Chicago among infants 1 year old or under per thousand of population for the corresponding years.

The infants in division B seemed less serious, as a whole, than those in A, but more serious than those in C. They were accordingly given, not exclusively breast milk, but comparatively large amounts, to tide them over a critical period. The change for the better and the upward progress of most of these infants took place coincidently with the change to, and administration of, breast milk, and I believe the low mortality among them to be due to the considerable amounts of this milk received.

The infants in division C seemed somewhat less serious than those in either A or B; accordingly they received less breast milk and had a high mortality rate, half of them dying.

The high mortality in division A emphasizes the fact that human milk is not a panacea for all the ills of infancy, but in many cases is of no avail. Intensive study of such cases, by clinical and laboratory methods, will probably show that some combination of water and solids other than that found in breast milk is better adapted to correct the chemicophysical condition in which these infants enter the hospital.

The low and high mortality of divisions B and C, respectively, is significant: the one group received breast milk in abundance and suffered a mortality of only 3 per cent.; the other was "skimped" on breast milk and half died. The lesson is obvious.

MORTALITY BY YEARS

We have seen that the mortality rate of a group of babies fed partly on breast milk and partly on cow's milk is somewhat lower than that of a group of equal vigor fed on cow's milk alone, the investigation covering a period of three years. What has been the effect on the hospital infant death-rate as a whole? Is this lower on an average than it was before breast milk was used so extensively? Is the number of recoveries among the breast-fed babies sufficiently large to influence the general mortality?

The hospital infant mortality-rate as a whole has been ascertained for the years 1910 to 1913, inclusive; the mortality-rate in Groups 1 and 2 has been estimated yearly; finally, as an infant's hospital is apt to reflect in the severity of its cases, the severity of the same diseases prevailing in the community at large, figures of the infantile death-rate in Chicago, during the same period, are introduced for purposes of comparison. Curves have then been plotted, based on these figures in the accompanying chart.

Analysis of the curves as a whole is interesting. All show a drop from 1910 to 1911, the hospital curves reflecting the general drop seen in the city curve; from 1911 to 1912 there is a sharp rise in the cow-milk group, carrying up the general hospital rate, a reflection again of the increased city mortality; from 1912 to 1913 we see a marked drop in the cow-milk group, carrying down the general hospital rate, in spite of a continued rise in the city at large.

In the breast-milk curve, the high figures seen in 1909 and 1910 have already been explained. They are due to the scanty, irregular use of breast milk. They are of little significance but serve as a background and contrast to the marked decrease in the following two years, during which breast milk was used extensively. Especially interesting is the drop in 1912 coincidently with the rise in all the other curves, both of hospital and of city. Notwithstanding a season of severe intestinal troubles, we were able to save an increased number of babies taking breast milk, while the number of deaths of those taking cow's milk markedly increased, from 27 per cent. to 48 per cent.

There is a rise in the curve in 1913; it is, however, slight, only 2 per cent., and may well be due to the presence of an unusual number of well nigh hopeless cases, there being on the list two cases of pyloric stenosis, one of erysipelas and ten of bronchopneumonia in a total of fifty-seven cases for the year.

In the curve based on the hospital infant mortality as a whole, we see that the mortality for 1910, before the extensive use of breast milk, was 36 per cent., and that it was 33 per cent., 42 per cent. and 32 per cent. for 1911, 1912 and 1913, respectively. Two of these last three years thus show a decreased death-rate, but in the third year, 1912, the rate was so high that the average for the whole period was 35.6 per cent., practically the same as in 1910, before the extensive use of breast milk was begun. Thus the average general rate has not been lowered by the use of breast milk. We have undoubtedly saved lives by its use, but not in numbers sufficient to lower the general infant death-rate. The time covered by the study, however, three years, is too short to warrant final conclusions and the figures are introduced only as a preliminary report.

DURATION AND COMPLICATIONS

One of the unfortunate factors in the management of hospital babies and one contributing largely to the high mortality is their prolonged stay in hospital. It seemed desirable in the present study to ascertain whether or not the breast-fed babies made more rapid progress than the others; whether or not, also, they were less apt to contract communicable disease. Accordingly Groups 1 and 2a were analyzed from these points of view. The average length of stay of all recoveries was estimated, likewise the number of complications among both the recoveries and the fatal cases. The results are as follows:

Average stay of Group 1 was 54 days
Average stay of Group 2a was 34 days
37 per cent. of Group 1 developed complications
24 per cent. of Group 2a developed complications

The more protracted stay of the breast-fed infants is striking. The greater proportion of complications among them follows as a natural result of this long stay; of the sixty-two cases with complications, only six had a complication on admission. Furthermore, the complications are more fatal among the breast-fed infants, 37 per cent. of these dying, as compared with 27 per cent. in the other group.

It is probable that in our desire to give the babies every possible chance we have kept them on breast milk too long, thereby delaying their discharge from the hospital. It apparently has not been possible to furnish them breast milk at home, and they have stayed until they have been "switched" to an exclusively cow-milk diet on which they could be sent home.

The problem is difficult, though not insurmountable. On the one hand is the necessity of feeding to a weak baby the food which in all probability will give him the best chance for life; namely, breast milk. On the other hand is the continued exposure to communicable disease—exposure of a baby with an already lowered resisting power. The solution of the problem lies in the earlier discharge from hospital and the continued use of breast milk from the hospital wet-nurse, oversight of the patient at home being continued through the out-patient and social service departments.

CONCLUSIONS

Comparative study of two groups of infants of unequal age and weight, the older and heavier group fed exclusively on cow's milk, the lighter and younger group on part human and part bovine milk, shows that the mortality-rate in both groups is the same.

Study of two groups of the same age and weight, fed as above, shows a mortality lower by 8 per cent. in the group fed partly on breast milk.

Infants seriously but not hopelessly ill, whose diet consisted of at least half breast milk over a critical period, show a mortality of but 3 per cent.

Infants somewhat less seriously sick, whose diet consisted of less than half breast milk, over a similar period show a mortality of 50 per cent.

Whenever possible, therefore, the diet of such seriously ill babies should consist of at least half breast milk throughout the critical period of their illness.

The use of a limited supply of breast milk in a large infant hospital, over a period of three years, has not reduced the infant mortality of that hospital during that period. The mortality, however, has not risen, notwithstanding the fact that during the same period there has been a steadily rising infant mortality in the city in which the hospital is located and from the infant population of which the hospital draws its patients.

Breast milk is not a panacea for all the ills of infancy, desperately ill infants showing a high mortality even when fed exclusively this kind of food.

URINARY ANALYSIS IN THE DIAGNOSIS AND TREATMENT OF DISEASES OF INFANCY AND CHILDHOOD *

ROWLAND GODFREY FREEMAN, M.D.
NEW YORK

It is the design of this paper to point out the importance of fairly complete urinary examinations in disorders of infancy and the value of certain tests infrequently made which may furnish important information. The urinary analysis recommended may be run through in ten or fifteen minutes by a competent man in any properly equipped laboratory.

I am aware, of course, of the ordinary office examinations of busy physicians, the tests for albumin and for sugar, and also of the fact that commercial laboratories are used by many physicians to obtain more complete examinations without trouble to the physician himself. But it is not often that office examinations or laboratory examinations supply the physician with the most important facts to be elicited from the urine in the diagnosis of diseases of infancy and childhood, while in the case of infants where the procuring of a specimen is difficult, urinary analysis is often completely neglected. This neglect is in sharp contrast to the frequency of blood examinations in such cases, blood being readily procured by a prick.

The examination of a specimen of urine in a child acutely sick, especially if the diagnosis is obscure, is usually much more important than an examination of the blood or any other examination excepting the general physical examination by the physician.

The obtaining of a specimen of urine, while often difficult, especially in female children, is not really so difficult as is generally supposed. One difficulty is that infants pass a little urine very often. Accurate obser-

---

* Read before the Section on Diseases of Children at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

vations on the urination of infants have recently been made by Engle[1] who placed an infant over a receptacle for the urine so arranged that an electric current was formed which rang a bell whenever the child moistened the receptacle with urine. He found that an average infant taking about 800 c.c. (27 ounces) of food urinates from twenty-five to thirty times in twenty-four hours, or oftener than once an hour, and when the food was increased to 1,600 c.c. (54 ounces) the child would urinate from fifty to sixty times or more in twenty-four hours; that is, every twenty or thirty minutes. He also found that a young infant voided urine at regular intervals whether awake or asleep, while after 6 months of age they usually urinate only while awake.

While cribs have been made with receptacles for saving all the urine, for ordinary clinical purposes this is not necessary. In a male infant a bottle with a mouth sufficiently large for the insertion of the penis may be fastened to the child with plaster with full assurance that a specimen will be obtained within an hour if the child is awake. In a female infant the procuring of a specimen is more difficult, but a small cup placed under the infant whenever she wakes with a dry diaper, especially if pressure is made over the bladder, which at this age is an abdominal organ, will usually procure a specimen. If it does not, the next opportunity will be when a bottle is given, for during the time when a baby sucks at a bottle urine is apt to be excreted. In cases of pyelitis in female infants I have had no trouble, where there has been intelligent supervision, in securing several specimens a day without the use of any apparatus.

Of the conditions to be looked for in the urine we may note in order:

1. Dilution
2. Evidences of nephritis
3. Evidences of diabetes
4. Evidences of acidity
5. Evidences of acidosis
6. Evidences of intestinal intoxication
7. Evidences of pyelitis

But it is the acidosis, intestinal intoxication and pyelitis that I wish to emphasize, these being the important conditions to be constantly looked for in the disorders of childhood.

URINALYSIS

Before considering these abnormal conditions found in the urine of children I will review briefly the sort of urinalysis which I believe is essential to the intelligent diagnosis and treatment of disorders of children. This analysis, when the materials are ready, may be run through in a few moments.

The specific gravity is taken in the ordinary way with a urinometer.

A qualitative reaction may be obtained by the use of litmus paper, but for a quantitative reaction, which is quite important in treatment, a more accurate test with phenolphthalein is of advantage. For this purpose a phenolphthalein solution, a buret containing a decinormal sodium solution and a few grains of potassium oxalate are necessary. Twenty-five cubic centimeters of urine and a few grains of potassium oxalate are put into a test-tube and shaken. Two drops of phenolphthalein solution are added, and then drop by drop the normal sodium solution until the reaction occurs which is read off in cubic centimeters on the buret.

Albumin may be detected by the use of strong nitrate acid in cold urine or by boiling the urine and adding a few drops of acetic acid.

Glucose is detected by Fehling's solution, and if positive, is confirmed by a fermentation test with yeast.

To obtain acetone the urine is shaken up with a few drops of a freshly prepared sodium-nitroprussid solution. To this 2 c.c. of glacial acetic acid are added and over this a layer of 10 per cent. ammonia water. After standing three minutes a red ring indicates the presence of acetone.

For diacetic acid a 10 per cent. ferric chlorid solution is added to 5 c.c. of urine until the mixture clears. A Burgundy red-color indicates diacetic acid, the amount varying with the saturation of the color.

For indican, to 5 c.c. of urine 5 c.c. of strong hydrochloric acid are added. To this a drop of sodium hypochlorite solution and a few drops of chloroform are added. The test tube is inverted five or six times and allowed to stand for five minutes. A violet color indicates indican, while a red color indicates potassium iodid.

For phenol 5 c.c. of Millon's reagent are added to 1 c.c. of urine. This is boiled and a salmon pink color indicates the presence of phenol.

These tests are only a few readily made tests to indicate certain conditions. Acetone and diacetic acid are only two of the products of acidosis. Beta-oxybutyric acid, a third and earlier form of acidosis, is more difficult to test for and of less consequence.

Other substances that give evidence of intestinal intoxication likewise may be tested for, but these two, indican and phenol, are good representatives of the class and give one readily an indication of what one is dealing with, and I believe that these tests together with the test for bile, if necessary, and thorough microscopic examination of the sediment are all that are necessary for routine work.

The dilution of urine is indicated by its specific gravity. The specific gravity of the urine may give one a good clew to the amount of fluid taken, and while in those who are largely on a fluid diet the specific gravity is low, it is not uncommon in children of 3 or 4 years of age to find a very high specific gravity, and these children are usually those who take very little milk or other fluid.

ALBUMIN

The presence of albumin in the urine of children who have general disorders is not, to my mind, a necessary source of concern. Traces of albumin are very frequently found and unless this albumin occurs in a child with a nephritic history or is associated with or preceded by acute nephritic disorder, one may assume that it will disappear with an amelioration in the general condition of the child. The same may be said of hyaline casts in the urine, which in some children will occur in large numbers, and sometimes without the presence of albumin, and these casts may not signify any grave disorder.

Sugar is rarely found in the urine of children even in cases of marked acidoses. If it is found the possibility of a physiologic glycosuria due to overindulgence in sugar should be borne in mind, but the persistence of sugar in a normally fed child is one of the gravest indications, diabetes in these young patients being almost universally fatal.

---

[1] Engle: Rev. in Therap. Monatsch., 1912, xxvi, No. 5, p. 318.

Intense acidity of the urine unaccompanied by the products which we call an acidosis may produce such symptoms as intertrigo and frequent micturition, which are readily relieved by a neutralization of the urine by the internal administration of alkalies.

ACIDOSES

To attempt to give a review of the theories of the cause and significance of acidoses would take more time than we have, and would not lead us probably to any definite conclusions. Acidoses have been mostly studied as they occur during the disturbances of pregnancy, particularly as they occur in diabetes, in acute yellow atrophy of the liver and after chloroform anesthesia.

All this literature, however, we will lay aside to consider the association of acidoses in the common ailments in children and their treatment.

By acidosis I mean a condition associated with a considerable amount of acetone and diacetic acid in the urine. In any urine that is very markedly acid in children the presence of these substances should be suspected and looked for. A fairly regular accompaniment of these attacks of acidoses is the flavor of acetone in the breath of the child, and on this alone a diagnosis can often be made. Acetone may, however, occur in the urine unaccompanied by acetone breath, and acetone and diacetic acid may be present in a urine that gives an alkaline reaction. An acidosis occurring in very early life is that found in breast fed babies who are taking and retaining more breast milk than they can properly digest. They have frequent movements that are markedly acid. They become irritated under the diaper and if the food is not cut down will soon break out in an acute general eczema. In such cases the remedy is easy of application. By weighing before and after nursing one may ascertain the amount of milk the child is getting at each nursing, and this is often 5 to 6 ounces in a child 6 weeks old, and when the breast feeding is cut down to a suitable amount the eczema rapidly disappears and the child recovers.

Almost all intertrigo in babies is caused by an acid urine and this may be associated with the presence of acetone and diacetic acid. This condition is most successfully combated by a neutralization of the urine in addition to the use of external applications. In neutralizing the urine care must be taken that it is not made strongly alkaline, for I believe it may then be as irritating as before.

Most of the attacks of vomiting in children are accompaniments of acidoses, excepting those caused by an overloaded stomach, while in persistent attacks of vomiting the condition of acidosis is usually very marked. Those cases known as cyclic vomiting, where children from 3 to 10 years of age have repeated attacks of vomiting with a markedly acetone breath which last for a number of days, while not necessarily due entirely to acidosis—for in these cases there is a large nervous element—are usually preceded and accompanied by acidoses and are best treated by alkalies and elimination. These attacks are best controlled by excluding nervous irritation, by watching the tongue of the child and on the slightest indication of a recurrence of an attack, putting it to bed, relaxing it with a warm bath, and administering alkalies and laxatives. By these methods, promptly and vigorously applied, the habit of recurring attacks may best be broken.

INTESTINAL INTOXICATION

In addition to these attacks of acidoses we have another class of cases called intestinal intoxication which may or may not be associated with acidoses. Attacks of intestinal intoxication are characterized by the presence of indican and phenol in the urine. Such attacks are common in young children and an appreciation of their nature is an aid in intelligent treatment. One of the earliest accompaniments of this condition is seen in marasmic babies during the first months of life, who after a stationary weight or a gradual loss in weight, show in one day a gain of from ½ to ¾ pound, and on examination it is found that there is an edema of the hands and feet or of the face. These are usually severe cases and often terminate fatally, and this edema is often associated with intestinal intoxication, while the stimulating cause may be the administration of too much sodium chlorid.

Another group of cases are those that have urticaria with localized edema. It is not very uncommon that a child who has been doing pretty well, except possibly for a coated tongue, is found one morning with one eye entirely closed from swelling. He has little or no fever, is less active than usual, and may have no other swelling, but sooner or later other evidences of urticaria appear. If with these attacks the child vomits, we usually find an acidosis associated with the intestinal intoxication. Examination of the urine in these cases is very important in eliminating a diagnosis of a much more serious condition. As these children improve under treatment the evidences of acidosis and intestinal intoxication disappear.

The eczema of childhood which is often resistant to the treatment administered is usually curable if the food is carefully regulated on a basis of required calories, the intestinal intoxication eliminated and the surface kept well covered with appropriate ointment. The treatment of these intestinal intoxication cases is very similar to that used in acidoses—free elimination from the intestinal tract and the administration of alkalies. In the administration of alkalies, however, both in acidoses and in intestinal toxemias, careful control of the reaction of the urine must be had by the use of litmus paper or phenolphthalein, so that when a neutral or slightly alkaline reaction is reached the alkalies may be reduced in dose or discontinued. The alkalies that are most valuable for this purpose, as being in no way irritating and well taken by children, are the bicarbonate and citrate of soda, while milk of magnesia, which is strongly alkaline, makes a good laxative to use in combination with the bicarbonate and citrate of soda. Lacto-bacillary cultures may also be administered with benefit in cases with offensive stools, or with abdominal distention from gas formation.

The growing pains of children are often associated with acidoses and intestinal intoxications and may be relieved by treatment which rectifies these irregularities.

PYELITIS

The third condition in the urine which should be carefully looked for in every case of unexplained fever is pyelitis. Cases of pyelitis, many of which are readily curable, are more commonly allowed to run on unrecognized than any other disease of infancy, not excepting otitis and scurvy; for pyelitis may give no evident clew to diagnosis unless the urine is examined.

The laboratory diagnosis is made by finding in the precipitate of a centrifugalized specimen of urine a material number of leukocytes. One or two leukocytes in a D-field (Zeiss) of precipitate of a female baby does not indicate a pyelitis, but only the washing from the vulva. That number, however, in a male baby or more in a female baby should render the diagnosis suspicious, and then other specimens obtained so as to avoid contamination should be examined for both leukocytes and bacteria.

A clean sample may be obtained by using a bottle and cork that have been in boiling water, by rinsing the chamber with boiling water and washing thoroughly the urethral orifice in a male baby and the urethral orifice and vulva in the female. With these precautions taken one usually obtains almost a pure culture of the infecting organism. Or in pyelitis cases the specimen may be obtained by a sterile catheter into a boiled bottle or sterilized test-tube.

The pyelitis of infancy is an acute infection which may or may not be accompanied by fever, but which, in any event, should be promptly cured, for cases that have not been cured and have gone on to a fatal termination have shown suppurative processes in the kidney tissue. The diagnosis of pyelitis is often fairly sure before the urinary examination is made, if one is accustomed to the type of symptoms that accompany it. The temperature is usually of a marked remittent type and in severe cases is apt to reach more than 105 F. and sometimes 106 F. It occurs usually in children near the end of the first year, and far more often in female children than in male. On this account pediatricians are apt to feel that the infection has come from the outside through the smearing of the colon-bearing stools over the buttocks of the child, thus reaching the vulva, and the infection traveling up the urethra. The inside infection through the lymphatics is, of course, possible, and may frequently occur, but the greater incidence of pyelitis in female children can best be explained on the theory of external contamination. This likelihood of external contamination is one of the strongest arguments for the early control of defecation in children. Children with intelligent nurses may be trained by the aid of glycerin suppositories to have a morning movement in a bowl when not more than 2 or 3 months old. The formation of such a habit in early life should not be neglected.

Pyelitis is likely to be preceded by a disturbance of the bowels, usually not an acute colitis, but a condition in which the movements are a little green and perhaps slightly more numerous than normal. The attack of pyelitis is usually ushered in by a slight rise of temperature, which most often quickly subsides on the administration of sufficient alkalies to neutralize the urine, and many authorities believe that this administration of alkalies should be the main reliance in pyelitis.

Although cases of pyelitis are almost all colon infections, the reaction to treatment varies materially, and while most children are cured by neutralization of the urine by alkalies, there remain many children in whom this treatment has apparently no effect, and for these cases other methods of treatment must be sought. Perhaps the best treatment in many cases for the cure of the constitutional symptoms is the administration of colon vaccines which produce a reduction in the temperature; but so far as I know, the vaccines do not cure the disease, though they apparently cure it. The child loses its fever and will increase in weight and seem perfectly well, but when the urine is examined one finds the same pus and bacteria that existed before. We fortunately have now the first internal antiseptic that has ever proved efficient for any part of the body, and hexamethylenamin is certainly an absolute antiseptic for certain infections of the urinary tract. It, however, is a drug that should be given with care to infants:

I have seen marked cyanosis follow the administration of one-half grain of hexamethylenamin in a child 8 months old, and a similar attack follow the second administration of the same dose. So in no infant should doses be begun of more than ½ grain; but if the infant and its urine can be carefully watched and no reaction follows the administration of ½ grain, the dose can be rapidly increased. I have, however, administered a dram a day of hexamethylenamin to two babies of 6 months with colon cystitis and acid urine, neither weighing more than 12 pounds, without causing any evident irritation of the kidneys and without curing the cystitis. Such large doses if given should be continued only a few days, during which time the child and its urine should be under close daily observation for evidences of kidney irritation.

CONCLUSIONS

In every urinary analysis in children, whether with fever or without, careful tests for acidity, for acidosis and intestinal intoxication should be made, and also an accurate computation of the number of leukocytes present. Should these leukocytes be constantly present in any considerably increased amount an examination for bacteria in a fresh specimen procured in such a manner as to avoid contamination or drawn by a catheter, should be made and if present should be grown on culture media for identification. By neglecting to make these tests many failures to properly diagnose and promptly cure disorders in childhood may occur.

211 West Fifty-Seventh Street.

ABSTRACT OF DISCUSSION

Dr. J. P. Sedgwick, Minneapolis: At the St. Louis meeting of this section I was able to report that in recurrent vomiting we have a greatly increased amount of creatin and creatinin, especially creatinin. At Chicago a year or two later I was able to show that increased creatin and creatinin excretion accompanies the attack. In the meantime Mellanby had reported that the creatin and creatinin excretion and acidosis increase with attacks of recurrent vomiting. It has been shown by physiologists that acidosis is produced and occurs with the withdrawal of food, especially with the withdrawal of carbohydrates, and creatin and creatinin excretion also increase under the same conditions. I think we should be careful not to mistake the acidosis for the cause or the fundamental part of recurrent vomiting, when we do know that the withdrawal of food, especially carbohydrates, or an increase in the amount of fat ingested, will produce these acids. I think many have made the mistake of considering the effect to be the cause. Based on the fact that infections of the urinary tract occur more frequently in female children, we think it must be due to infection through the urethra. We have not been able to find any experimental proof. Dr. Huenekens worked with me, trying to cause ascending infection in guinea-pigs, but we were not able to accomplish it.

Dr. S. M. Hamill, Philadelphia: Will Dr. Sedgwick say what relation creatin and creatinin bear to these attacks? Is elimination increased before the attack? In other words, is it a premonitory symptom?

Dr. Sedgwick: Mellanby's report shows that he found an increase of creatin and creatinin as well as acidosis just before the attack. I reported one case in which a child having repeated attacks of recurrent vomiting, also had fever and appeared to be coming down with an attack of recurrent vomiting, and creatin and creatinin did increase without the typical vomiting. In many cases when we had recurrent vomiting, I did not get much increase in creatin and creatinin before vomiting. Of course acidosis and acid bodies come up at the same time—I believe in many cases owing to the withdrawal of carbohydrates.

Dr. Joseph I. Linde, New Haven, Conn.: It is important to get complete specimens of urine, or at least several specimens during the day. Pus is not present in all specimens during the day, and if several specimens are not examined one may easily fail on the diagnosis.

Dr. Henry F. Helmholz, Chicago: I wish to emphasize a point made by Dr. Linde, not only to take several specimens on one day, but specimens for several days running, especially in those chronic cases, in which one may find no pus for several days. In recurring cases, in which the symptoms are indefinite, one sometimes gets a sudden gush of pus after practically negative urinary examinations covering a period of several days. With regard to the finding of albumin in the urine in older children, one case is well recognized, namely, orthostatic albuminuria, which should be considered, because, by means of exercises, this condition can be cured. Whether or not it is of any great harm to the child to be excreting albumin, is not for me to decide. In this well-defined group of orthostatic albuminuria we have an explanation of why the child is passing albumin. Dr. Freeman called attention to overfeeding; it seems to me just as important to recognize cases of acidoses caused by underfeeding. As Dr. Sedgwick has said, the withdrawal of carbohydrates gives rise to this condition, and in children who are underfed a very good indication of this is the presence of diacetic acid in the urine.

Dr. W. W. Butterworth, New Orleans: If, through Dr. Freeman's paper the attention of the general practitioner can be called to the great need of examining the urine of infants and children more frequently than is generally done, we will have accomplished a great deal. It is easy to secure a specimen of urine from infants—especially female infants. Apart from albumin and sugar examination, the test for indican, acetone bodies and the presence of pus is important. Another thing which should be mentioned is the frequency of pyelitis occurring in boys as well as in girls. At the last meeting of the International Medical Association, Dr. Thompson of Edinburgh reported twenty-seven cases of pyelitis occurring in boys. I, as well as others, had lost sight of the fact that it occurs more frequently in girls than boys. My fatalities have occurred in boys instead of girls. Just why is not clear to me. I believe we are apt to overestimate the importance of acetone and diacetic bodies in the urine. Almost any febrile disturbance will cause their presence. The simple finding of them does not mean acidosis.

Dr. Henry Heiman, New York: First in importance is the examination of the urine at various times. In orthostatic albuminuria, if we examine the first specimen before the patient is out of bed, we will find it negative. As soon as he is up and around the albuminuria will be present. We know this is probably due to pressure on the venous system of the kidneys. It is better to take morning and evening specimens in cases of suspected orthostatic albuminuria. In infectious diseases, when we examine the first twenty-four-hour specimen we find it as a rule containing albumin, but we all know that real nephritis occurs later, as in the third week in scarlet fever. With regard to obtaining urine in children, I have been fairly successful with Dr. Chapin's receptacle. In females I never hesitate to catheterize when necessary with a small ureteral catheter. This is thoroughly sterilized, of course. There is no difficulty in obtaining urine. With regard to types of pyelitis, we all believe we have ascending, descending and transparietal types. My experience has been that they are much more frequent, in New York, in females than in males. We should state specifically with what type of pyelitis we are dealing. The majority are due to the *Bacillus coli communis*. I have one case in the hospital of the pyocyaneus type. I believe the majority are of the ascending type. The colon bacillus has been found in the blood, but in rare instances. With regard to the treatment of these patients, I must say if they do not get well in ten or twelve days with or without urotropin, they become chronic. The Germans believe, in such cases as have been mentioned, in which there is free urine for several days and a relapse, that it is due to punctate abscesses in the cortex of the kidney. For the diagnosis of these cases Dr. Edwin Beer has given an excellent test—methylene blue. For a few days the urine will be green, then it becomes normal, then when an abscess bursts, it will be green again. This test is a very useful one.

Dr. Kate C. Meade, Middletown, Conn.: Is it possible, by regulating the urine, to control the eczema which these children sometimes have?

Dr. R. G. Freeman, New York: A variation in the amount of pus in the urine at different times in the day does of course occur. As to using the urine from a squeezed diaper, that is better than nothing, but one never knows what the diaper may contain, and what it does contain will appear in the urine. It is perfectly simple to obtain a specimen in a clean vessel in all cases. I think modifying the urine aids much, but diet is the main factor in eczema.

AMEBIC DYSENTERY IN CHILDREN*

L. R. DeBUYS, M.D.
Assistant Professor Diseases of Children, Tulane University of Louisiana
NEW ORLEANS

Amebic dysentery is a relatively rare disease in children, not because children are not susceptible to the infection but because they are less exposed to the etiologic factors which cause the infection in the adult. It is possible that in children it may exist much more often than is believed but may escape detection. The four cases reported below are instances of this.

In the Charity Hospital in New Orleans where there have been seen in the out-patient department for the last eight and a half years an average of 20,543 new cases annually, and where there have been admitted annually an average of 11,077 cases, or where 94,161 cases have been admitted, only 313 were cases of amebic dysentery, and of these four occurred in children under 12 years. Two of these were in my service.

At the Touro Infirmary in my service in over 3,000 children there were four cases of amebic dysentery. Two of these children were admitted to the Charity Hospital, because the Touro beds were filled, and are included in the four cases in the Charity Hospital. Besides my four cases at the Touro Infirmary there were two others, making a total of six cases at this institution.

Of the eight cases, one, after the condition was diagnosed, deserted.

Amebic dysentery is more prevalent in the male than in the female, due, it is generally believed, to the more active life of the male with the incident greater exposure; and so it might be argued, the lesser exposure may hold good for the relative infrequency in children. The younger the child the less often is the disease found. This is in accord with our belief of the sources of infection, more particularly water and green vegetables, as the smaller babies have boiled water, as a rule, and do not yet have vegetables. As they grow older the exposure, and consequent liability to infection is greater.

The symptoms of amebic dysentery in children do not differ from those in the adult. The abdominal pain, the frequent stools containing mucus, blood and, at times pus, the tenesmus, anorexia, indigestion, anemia, emaciation and low temperature, loss of weight, flabbiness of muscles, dry skin and sallow complexion are more or less constantly found, depending on the severity of the disease. The blood picture is one of secondary anemia.

---

* Read before the Section on Diseases of Children at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

The diagnosis is not difficult to make if a microscopic examination of the warm, liquid stool, free from urine, is made; or better still, if a rectal tube is passed and the bloody mucus or small pieces of necrotic tissue thereon are examined on warm slides. The ameba will be most readily found in this way. The condition from which amebic dysentery is to be differentiated in children is bacillary dysentery. In the latter condition the onset is usually more acute, temperature higher, systemic disturbance greater, the child is more toxic and less sallow, and the agglutination test *may be positive, and the dysentery bacilli but no* amebas are found in the stools. The facies in the two dysenteries are different and characteristic in each.

† Inactive.

The prognosis depends on the severity of the disease and the complications, more particularly abscess of the liver, terminal infection, exhaustion in protracted cases, and intercurrent diseases.

Conclusions cannot be drawn from a few cases but in a condition as infrequent as is amebic dysentery in children, it is excusable to venture some suggestions from the study of a few cases.

The treatment of the seven cases (because one of the eight patients deserted after the diagnosis was made) referred to in the beginning of this paper consisted of ipecac in two cases and emetin in five cases. The two patients who were given the ipecac in the form of pills were 11 years and 6 years and they received 380 grains in 27 days and 243 grains in 25 days, respectively. In a third case ipecac was attempted but because of the inability of the patient to swallow the ipecac pills emetin was given with, I am told, satisfactory results. The four remaining patients, aged 8 5/12, 7, 4 and 4 years, respectively were given emetin. The 7-year-old child was given 4⅔ grains in five days, being given ⅓ grain three times a day. The amebas disappeared from the stools on the fourth day. The plan adopted in the treatment of my three patients was to pass the tube daily, and as long as amebas were found to give 1 grain emetin hypodermatically at one dose daily. When the amebas were no longer found the tube was passed every other day for two or three observations; then the interval of passing the tube was lengthened. The passing of the tube was not discontinued until after magnesium sulphate or castor oil was given and no amebas found.

The diet should be liquid until the blood and mucus disappear, when soft food may be given. Rest is absolutely essential, not only to the individual, but to the bowel. Emetin seems to provide rest to the latter.

CASE REPORTS

CASE 1.—F. A., white male, 1 year and 11 months old, native of Louisiana and resident of Donner, La., was brought to my clinic at Touro Infirmary, Nov. 8, 1912, because of loose, bloody stools.

His family history was negative, except that there had been two miscarriages. There were three well children and no bowel trouble in the family. He was a full-term child and born after a difficult labor. He was breast-fed and after his fourteenth month ate everything. His development was normal. He had had no other illnesses.

In June, 1912, his present trouble began with frequent stools, twelve to fifteen a day, containing slime and much blood, and accompanied with pain and straining. In August there appeared a lump in the left inguinal region which disappeared from time to time. During the present illness the patient has had slight fever.

Physical examination showed a fairly developed child weighing 21 pounds. He had a small left inguinal hernia. A rectal tube was passed and amebas were found. Otherwise his examination was negative. He was given an admission card but was not seen again. This is the patient that has been alluded to as having deserted.

CASE 2.—W. O., white male, 4 years old, native of Louisiana, was brought to me July 25, 1913, from Baton Rouge, La., with a complaint of frequent and bloody stools.

His father and mother were both living and healthy as were also his two sisters and one brother. There was no other member in the household with bowel trouble.

He was a full-term child delivered normally. He was fed exclusively on the breast for nine months, after which cereals and a proprietary food were given until his eleventh month when he was gradually put on a full diet, eating everything at the age of three. When 2 years old he had fever for four days which was called "malaria." The diagnosis, however, was not confirmed microscopically.

The patient lived in the suburbs of the city but used the water furnished by the city's waterworks. He was very fond of green vegetables, which he frequently stole and ate.

In November, 1912, he ate a great number of green pecans and within a week afterward his stools became loose, there being two or three movements daily. About one month later his stools became worse and the movements were accompanied by severe straining. They contained a great deal of blood and mucus. His stools were very frequent—from twelve to twenty-six daily. He was relieved somewhat after a consultation was held by two physicians, but this relief was only temporary. He had experienced periods of relief followed by relapses intermittently since the onset of the disease. The patient had lost much weight from December, 1912, to March, 1913.

He was admitted into Touro Infirmary on the evening of July 25, 1913, with a temperature of 98.6 F., pulse 102, respiration 24. He had no stool during the night.

On the morning of July 26 a rectal tube was passed and amebas were found. He was given emetin, ⅔ grain, by needle, was kept in bed and was put on liquid diet. In the next twenty-four hours he had six stools which were loose, dark brown and contained mucus and blood. He complained of pain in his abdomen and strained much at stool. The next day the tube was passed again, amebas found, and emetin, 1 grain by needle was given. He continued to complain of pain in the abdomen, but straining at stool was not so marked. During the next twenty-four hours he had only four stools which were of the same character as during the previous twenty-four hours. His urine examination was negative, except that it contained much indican.

On July 28 the tube was passed, amebas found, though not so many, and another hypodermic of emetin, 1 grain, was given. There were no stools in the twenty-four hours following and the patient was fairly comfortable.

On July 29 the tube was passed and a few amebas (inactive) were found. Emetin, 1 grain, by needle was again administered. As before there were no stools in the twenty-four hours, but the patient remained in a perfectly comfortable condition.

* Urine negative except for indican.

‡ Few encysted; non-active.

§ Red blood-corpuscles.

On the morning of July 30 the passing of the tube showed no amebas. No emetin was administered but magnesium sulphate ʒii was given, from the effect of which he had three stools which were liquid and yellow and contained no blood and no mucus.

The tube was passed on the morning of July 31, twenty-two hours after the magnesium sulphate was given and no amebas were found. He was allowed to have soft food and continued to improve in every way. There was a tendency toward constipation which was met by the administration of milk of magnesia. The tube was passed every other day until Aug. 4, 1913, with negative findings. On August 4 he was again given magnesium sulphate and again the passing of the tube twenty-four hours afterward was negative. He was then placed on full diet and was hungry between meals. On August 8, after a negative finding on passing the tube, he was discharged as cured. The patient weighed 32 pounds, 11 ounces on July 27, 1913, and 34 pounds, 2 ounces on Aug. 4, 1913. Wassermann made on admission, July 26, 1913, was negative.

On August 24 he was brought back for observation. His parents stated that the previous week he had had as many as five stools daily and that the day before (August 23) he had vomited after drinking pop, had high fever and complained of pain in his stomach. While at home he had eaten everything. He had had a cold for the past week. He was readmitted into Touro Infirmary. He had a cough but examination was otherwise negative. His bowels were constipated. Physical examination was negative. On passing the tube no amebas were found. His urine examination was negative except for a small amount of indican. His blood showed a total white count of 9,300, small lymphocytes 35 per cent., large mononuclears 8 per cent., polymorphonuclear neutrophils 57 per cent.

* Urine negative except for indican.

The tube was passed again on August 26 with negative findings. There were no ova found at any time in his stools. Frequent reports have been received about the patient's condition and up to the present time, eleven months afterward, he has remained cured.

Case 3.—A. M., white male, 4 years old, native of Louisiana and resident of New Orleans, came to my clinic at Touro Infirmary on Sept. 2, 1913, because of frequent and bloody stools.

His father and mother and brother were all living and healthy. There was no dysentery in the family.

The patient was a full term child of normal delivery. He was breast fed exclusively for twelve months after which table food was added to his diet and at 21 months the breast was discontinued. His development was normal. At 18 months he had measles and whooping-cough, when he was ill for about four or five weeks.

He had used only city water but ate a considerable amount of candy from different stores, and he also ate some green fruit.

The present illness began fifteen weeks previous to this report, when patient complained of pain in his stomach and passed blood and mucus in his stools. He was taken to one of the hospitals where he was treated for two weeks without any results. Some time afterward he was taken to a physician who gave him a white medicine (presumably bismuth) which had a transient beneficial effect. In a week, however, the condition reappeared and the patient was brought to me. During the attacks of dysentery he had from twelve to twenty-four stools daily and complained of pain in the abdomen and much straining at stool.

He was brought to the out-patient department of Touro Infirmary Sept. 4, 1913. A rectal tube was passed, amebas found, and he was given emetin, ⅔ grain. The following day his mother reported that though the stools were liquid and there were four in the twenty-four hours she had noticed no blood, but some mucus. The passing of the tube showed amebas and he was given 1 grain emetin.

Sept. 6, 1913, there was a tendency toward constipation. The tube again showed amebas and he was given emetin, 1 grain. After this the mother did not return for the treatment and the patient was recorded as having deserted. Five days later she returned and the examination after passing the tube was negative. She brought the patient back on two occasions convenient for herself, and then again discontinued reporting.

Oct. 2, 1913, the patient was brought back to the clinic complaining that on September 27 blood reappeared in his stools and had continued daily since then. The stools were yellowish, the blood being passed mostly at the end of the stool. October 2, however, the stool was blackish. The patient had a good appetite and had eaten everything he wanted. On passing the tube amebas were found and the patient was given emetin, 1 grain. The next day the patient did not return. On the third day amebas were found again and emetin, 1 grain, was given. The mother then took it on herself not to return with the patient for further treatment as the child had improved, and the patient was again recorded as having deserted.

November 4 the patient was brought to the Touro out-patient department for the treatment of the same condition (frequent, bloody stools). The mother hesitated a long time before returning because she had discontinued of her own accord on the previous occasions. As there were no empty beds at Touro Infirmary and as it was believed best to treat the child in hospital, he was admitted into my service at Charity Hospital.

On admission he was given a dose of castor-oil. The next day the tube showed amebas in great numbers. He was given emetin, 1 grain daily, as long as amebas were found and for two days longer because of his previous unsatisfactory treatment. After the first twenty-four hours no active amebas were found and likewise after the second twenty-four hours. No amebas were seen for two consecutive days thereafter. The tube was then passed every other day for four days and finally twice weekly so that observations were carried over a period of three weeks. During his stay in the hospital it was extremely difficult to keep the patient in bed and whenever he saw the opportunity he would get up and play about in the ward.

His stools became a little loose and contained a small amount of mucus, but his mother took him away without his being discharged.

He returned again on Feb. 11, 1914, for the same condition. The treatment was again instituted and after four doses of emetin, 1 grain daily, it was discontinued as amebas were no longer found. After the first dose his bowels did not move but when they did move after the third dose there was no blood. On passing the tube three days after the last dose of emetin the presence of a few red blood-corpuscles caused the treatment to be begun again. Though no amebas were found he was given 5 grains of emetin in six days, one day being omitted through error. The tube was passed regularly after this and no further positive or suspicious findings were made. His mother took the patient away, after he had contracted a slight bronchitis on March 2, 1914, before he was discharged.

Since the last attack, which was treated under more favorable conditions than the previous ones, the patient remained well up to a report of one week before this was written.

Case 4.—M. R., white male, $8\frac{5}{12}$ years old, native of Louisiana and resident of Donaldsonville, La., was brought to my clinic at Touro Infirmary, May 26, 1914, for frequent stools containing blood.

He is the fifth child of eight, all of whom are healthy, as are the parents. His mother had four miscarriages and one stillbirth. An aunt died of tuberculosis five years ago. He was a full-term child of normal delivery and was breast fed for three months, after which he was given the bottle with milk and sweetened water.

Aside from the present illness he had never been sick. He usually drank cistern water and never well water. Three years ago a short time after eating of peanuts he passed much gas and later blood appeared in his stools. There were intervals when the dysentery would be much better, but recently he had become much worse. During the attacks he had much pain in his abdomen and strained a great deal at stool. The pain was more severe during the first three months of the illness. He had never had much fever. Four physicians were consulted at various times but none had ever made the diagnosis. One advised bringing him to the hospital. His mother thought that he was gradually becoming worse. He had never been confined to bed before he was admitted on May 26, 1914.

His stools were large, brown and contained mucus and blood. The tube was passed, amebas found and emetin, 1 grain, given. In all he was given 2 grains of emetin by needle after which the amebas were no longer found and the blood stopped. The tube was passed every day for four days after the first negative finding, then two days later with the same result. He was given castor-oil twice and magnesium sulphate twice and no amebas were found on passing the tube following the administration of the purgatives. Not much time has elapsed since this case was first treated but the patient is improving nicely.

DISCUSSION

Case 1 came from a district low and swampy and is of interest from a diagnostic point of view and because of the age of the patient.

Case 2 was given $3\frac{2}{3}$ grains emetin in four days. There was no blood after the second dose of emetin and no amebas were found after the fourth dose of emetin. This case is of especial interest because of the small amount of medication used; the prompt effect of the emetin in a case of such long duration (8 months); and the results of the treatment, eleven months having elapsed with no return of the illness.

Case 3 cannot be considered a fair test of any treatment, because (1) the first two attacks were treated without rest owing to the refusal of the parents to permit the patient to be admitted into the hospital; (2) the first two treatments were not completed; (3) during the third attack the patient was not kept in bed, and just at the time he should have been more closely observed, he deserted; (4) the fourth attack may have been due to no rest; and because (5) of the lack of intelligence and cooperation on the part of the parents, who gave the child all sorts of food when visiting him.

It must be borne in mind that there is a possibility of reinfection in this case, especially when the hygiene and habits (which were unfavorable) of the patient are considered.

The vomiting must be mentioned, as it is possible, though hardly probable, that the emetin alone caused it, because he did not vomit after each dose.

This case is of particular interest because of the relapses which may be accounted for as already mentioned. Also because it demonstrates the promptness of the effect of emetin in controlling the symptoms and the harmlessness of its large and continued dosage, and of its ultimate effect in the treatment.

It is too early yet to venture much in Case 4; suffice it to say, however, that the prompt effect of emetin was again demonstrated, since after the administration of 2 grains of emetin given in two days the blood disappeared and no amebas were found in the stools, and the effect was so prompt in a case of such long standing, (3 years).

All three patients were given 1 grain doses of emetin hypodermatically, and though it might be considered a large dose, no harmful effects resulted even in Case 3, in which the patient was given the drug on so many occasions and during one attack 5 grains in six days.

From the study of the foregoing cases and the literature I believe that emetin is the specific for amebic dysentery. There are some observers who have recorded cases treated satisfactorily and which have remained cured. There are others who have not reported such satisfactory results.

In the foregoing cases the effect of emetin was spectacular. After its administration the blood in the stools disappeared as if by magic; the amebas were soon no longer found, the stools were promptly diminished in frequency, and there was a tendency toward checking the bowels altogether and giving the necessary rest. Is there anything more to be desired? Undoubtedly it is the drug for children with amebic dysentery, as it may be given to them while quite young, its effect is rapid, and there are no disadvantages experienced as in endeavoring to have the child swallow ipecac pills or the inconvenience and struggle incident to colonic irrigation, and its effect is *certain.*

Maison Blanche Building.

ABSTRACT OF DISCUSSION

Dr. Thomas S. Southworth, New York: We of the North are prone to look on amebic dysentery as a matter of warm climates and the tropics. We see few cases, even in adults, unless the persons have been in some other portion of the country. Yet I doubt whether cases of dysentery have been sufficiently investigated for the presence of the ameba. Last summer I had an opportunity of seeing a woman of nearly 80 who had traveled only between Ohio and Maine, yet she had amebic dysentery which was promptly checked by the use of emetin hypodermatically. In these days when so much of our garden produce and fruit comes to us from the southern states, it is perfectly possible that the origin of this infection can be brought to us, and we should be more on the outlook for these cases in children. I believe we shall find more of them if we are watchful.

Dr. Henry Dwight Chapin, New York: This disease does occur rarely in New York. Every year we have one or two cases in the babies' ward of the Post Graduate Hospital. These patients have not been out of New York. Perhaps the disease is more common than we think, and we have not looked with sufficient diligence for the ameba.

Dr. J. W. Amesse, Denver: Any contribution to our knowledge of amebic dysentery should be welcomed, not only by this Section, but by the entire Association. It was a matter of common observation and comment among those who served in the Philippines during the early days of our occupation, that while amebic dysentery in adults was the *bête noire* of our daily life, few if any cases were found in children. I believe there is a relative age immunity to this disease, as there is to yellow fever, just as we find a relative race immunity among certain peoples to typhoid, hookworm disease, etc. So far as emetin is concerned, reports from every quarter warrant us in asserting that this powerful remedy is a specific for amebiasis comparable with quinin in malaria and antitoxin in diphtheria. I have seen amazing results follow its use in the practice of a colleague. Soldiers and civilians invalided home years ago and suffering periodic recrudescences of dysentery, have become practically transformed, and have again taken up their work as productive members of society.

Dr. W. W. Butterworth, New Orleans: The amebas in this country are wide-spread and not confined to the South. Neither are all amebas pathogenic. It is only when we have recurring attacks of dysentery, bloody mucus and straining, which pass away in a few days if not treated, to recur again, that our attention is called to the pathogenic amebic dysentery. Therein lies the important diagnostic point between pathogenic amebic dysentery and ordinary dysentery. I had an interesting experience in New Orleans, with a soldier who returned from the Philippines. He had barely escaped death in those islands; he was a married man, with a family of four children, the youngest of whom was 13 months old. This child was partially breast-fed. It was found to have amebic dysentery. Two of his other children, his wife and himself suffered from the same disease. It seems fairly reasonable that the infection occurred through the person of this returned soldier. I heartily concur in the value of emetin. It is the best agent we have in the treatment of this disease. Treatment by ipecac and flushing is most distressing and most annoying, and is frequently foregone by the patient. They will not subject themselves or their child to such a treatment. Emetin is far and away the best treatment we have of this condition.

Farmers Being Paid for Milk on Score-Card Basis.—For the past year or two the larger milk companies selling milk in this city have purchased milk from dairy farmers on the score-card basis. In general the contract provides for a premium of 10 cents per hundredweight for a score above 68, particular attention being given to methods of operation. That this is an effective incentive to the dairy farmer to produce milk according to modern standards is not open to question.—*Weekly Bull. Dept Health, City of New York.*

A YEAR'S EXPERIENCE WITH CONTAGIOUS-DISEASE NURSES*

WM. H. PRICE, M.D.

DETROIT

This paper assumes as established the fact that the taking of wholesome ways and reasonable precautions for the benefit of the public health may be expected to result in the prevention of disease, a healthier community, and more efficient individuals with lengthened lives. The truth of such a statement has come to be a matter of common knowledge. If evidence of it were needed, however, it is available in abundance, as witnessed by those spectacular sanitary reforms with which the world, lay as well as professional, is familiar.

With the prospect of such a reward, of disease prevented, dependents and public charges eliminated, and individual and community resources conserved, it is a source of wonderment that the preventable waste of disease and physical deficiencies continues to be endured. The explanation can only be in a lack of appreciation of these facts by laymen, by many physicians, and especially by those having in charge the appropriation of the public funds, when the principle of disease prevention is applied to their own household or community. It has therefore followed in natural sequence that education of the public has come to be a fundamental recourse for all activities having for their aim the protection and promotion of the public health. Some authorities even go so far as to state that efficient health measures are 80 per cent. educational.

Control of contagious disease is a rudimentary principle to be observed by all authorized public-health agencies. There are two reasons for this:

First, the problems of the control of communicable diseases are reduced to scientific exactness, and therefore greater results may be expected from the time, money and effort expended.

Secondly, public education regarding the possibility and advisability of reducing these diseases has progressed to such a point that the public demands their suppression as a prerequisite to the granting of further support, both moral and financial, for measures directed at more obscure diseases and defects in which all progressive health departments are interested, namely, housing, occupational, industrial and hereditary.

When, therefore, we embark on any program for the protection of the public health, it follows as a natural corollary that the suppression of contagious diseases is a prime requisite, and that the method of personal education directed at the known foci of infection is of greatest importance.

Previous to July 1, 1913, the following custom prevailed in Detroit relative to contagious diseases: The house was placarded immediately after the disease was reported. The next day a quarantine inspector visited the premises; his mission was to furnish fuel and groceries in needful cases, and to warn isolated persons against breaking quarantine. He called again as time and necessity indicated, and at the termination of the illness disinfected the house and removed the placard. Three inspectors were so employed at a salary of $1,000 per year each. They were faithful, reliable men with no pretense of hygienic training. Release cultures for diphtheria were taken by the tuberculosis nurses, thus involving a duplication of work by health-board employees.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

July 1, 1913, the quarantine inspection service was discontinued. Twelve contagious-disease nurses were appointed; tuberculosis, being a contagious disease, is included within the scope of their activities. These nurses are graduates and registered, or qualified for registration, and are each paid $1,000 per year. Districts are assigned according to density of population and facilities for transportation. A case of communicable disease being reported, the house is placarded, as formerly, by the police department. The same day, or at latest the next morning, a nurse visits the premies. A certain proportion of the patients go to the hospital, whereupon she immediately disinfects the house. Otherwise, she determines the advisability of isolating one room to permit the wage-earner to work and sleep at home. A card type history of the case and family is made out. Grocery supplies are furnished if necessary. The nurse's real mission, however, is to read over with the quarantined family the prophylactic literature published by the health board, which is similar to that furnished by other cities, referring to the particular disease in question, and also to give a practical demonstration of its application. Typhoid fever is a typical example. The nurse carries a half-pound can of chlorid of lime, a 6-ounce bottle of phenol (carbolic acid) and mosquito netting. A jug, a crock or other receptacle of two gallons' capacity is found and the chlorid is dissolved in two gallons of water, a basin of the solution is prepared and placed ready for the attendant's hands, disinfection of stools and urine are explained in detail, the phenol is made into a 5 per cent. solution with 1 gallon of water for disinfection of bedclothes and body linen. Antityphoid vaccination is urged. The windows and door of the sick-room are screened with mosquito netting, free if necessary. Return visits are made frequently and the supply of disinfectants is renewed. Account is kept of milk bottles to see that none are diverted to improper uses.

If subsequent infections take place in the family or neighborhood through the medium of flies or otherwise, it seems reasonable to assume that this must now be due to the wilfulness of the afflicted household. On termination of the illness, the house is disinfected by the same nurse.

Similar routine, varying with the character of the disease, applies to small-pox, diphtheria and scarlet fever. Perhaps a majority of the scarlet-fever cases are not seen by the doctor after the first week. At the end of the minimum period of quarantine it is the custom for the parent to call up the physician and notify him of that fact. He thereupon reports the patient as recovered. As a result of the careful examination of the patient before release, the average period of quarantine has been materially lengthened. The development of additional cases in the household is better reported.

Diphtheria cultures, both from schoolchildren, for release, and from suspicious cases at the request of physicians, are satisfactorily taken by the nurses. Reports are also returned to the main office of the progress of the illness and of the quantity of antitoxin used, thereby enabling the health officer to suggest, as diplomatically as possible, to the attending physician that doses of 2,000, 3,000 and 4,000 units for curative purposes are entirely inadequate and well calculated to perpetuate the disease and raise the death rate.

Objections on the part of the profession and the public to this system have been few and entirely out of proportion to the commendation it has received. The few objections have proceeded from two sources: First, the tradition on the part of certain physicians that disease is an individual affair of physician and patient. Such a contention is manifestly false. Contagious disease especially is not the personal affair of the individual, household or profession—the public is as much interested.

Secondly, there is a natural disposition on the part of the household to pump the nurse, as well as gossip with the neighbors and quiz the physician with the resulting information. Few practitioners have escaped the irritation of uncomplimentary remarks attributed to friends or other physicians before the introduction of the contagious-disease nurse, and in a few instances the nurses have been accused of talking too much. The nurse's training fits her perhaps better than any other individual to accomplish her purpose without suspicion of preempting the physician's field.

The following is a report of the contagious-disease situation in Detroit for the months of January, February, March, April and May, 1913, preceding the introduction of the contagious-disease-nurse system, as compared with the corresponding period in 1914, when that system was fully established:

COMPARISON OF FIRST FIVE MONTHS OF 1913 WITH SAME PERIOD IN 1914, WITH REGARD TO DEATHS FROM CONTAGIOUS DISEASES

	Deaths 1913	Deaths 1914	Reduction in 1914	Percentage of Reduction in 1914
Diphtheria	128	71	57	44
Scarlet fever	89	27	62	70
Typhoid fever	53	19	34	64

It is not sought to establish the conclusion that the contagious-disease nurse is alone responsible for the reduction shown above. The conclusion is drawn that she is a most valuable field agent of the health officer and the one best calculated to instil into the minds of quarantined persons the necessity for the taking of wholesome ways and reasonable preventive precautions. Also that the acquisition of obvious sanitary information by such persons is of the greatest importance in safeguarding the public health for two reasons; first, every infected person is a possible or even probable source of subsequent infections which should be guarded against at their source, and the attending physician has not as yet given sufficient attention to imparting this information; secondly, quarantined persons of the present will constitute themselves the professed authorities of the future in matters relating to communicable disease, and it is of the greatest importance that their views be definite and correct.

Pathology.—Pathologic anatomy which in other fields of pathology yields fundamental conceptions even on naked-eye inspection, in the case of mental diseases can neither provide clear data for clinical application nor be itself established without minute and painstaking microscopical research. And very often the latter demonstrates to us, in agreement with experimental data, that certain slight and transient influences, though not going the length of imprinting any sign of their passage on even such a delicate structure as the anatomical network, are still capable of inducing very grave functional disturbance.—Lugaro, Problems in Psychiatry.

CEREBELLAR SYMPTOMS AND CEREBELLAR LOCALIZATION

INCLUDING KINEMATOGRAPHIC OBSERVATIONS ON CEREBELLAR PHENOMENA [*]

RECENT ADVANCES IN CEREBELLAR SYMPTOMATOLOGY

In recent years, and especially under the lead of Babinški and Rothmann, some features of the old cerebellar symptomatology have come to be looked on in a different light and some of the symptoms regarded as elementary have been subjected to considerable dissection. The so-called cerebellar ataxia, now regarded as a symptom complex rather than as a pure symptom, has been more clearly differentiated from the ataxia of tabetics. Luciani's astasia, asthenia and atonia are acquiring a new interpretation.

Our studies emphasize the fact that asynergy is the fundamental symptom of cerebellar disease.

Cerebellar tremor and the new symptoms, hypermetry and adiadokocinesis, all now recognized as important cerebellar disorders, when reduced to their symptomatic elements, are seen to be dependent in large part if not entirely on loss or disturbance in the power of performing more or less complex movements together for the accomplishment of a definite end.

Luciani's asthenia, atonia and astasia are to be regarded not so much as special manifestations of asynergy as derivatives or resultants of asynergic effort. Asthenia is due to the exhaustion which results from efforts to perform movements which cannot be properly grouped and directed. Cerebellar atonia, which is very irregular in its expression, is a relaxation dependent on the fact that tonectic stimuli from the cerebral cortex cannot rhythmically combine with unsynergized movements. Primarily, tone is a cerebral, not a cerebellar attribute.

Attention may be fixed on the views just expressed by the following tabular statement:

Fundamental Symptom in Cerebellar Disease:
  Asynergy.
Special Symptomatic Manifestations of Asynergy:
  Hypermetry.
  Adiadokocinesis.
  Tremor.
Symptoms Resulting from Asynergic Efforts:
  Asthenia.
  Atonia.
  Ataxia.

Whether vertigo and nystagmus, which are so often present in disease of the cerebellum, are ever true cerebellar symptoms is a question which has been much discussed. From the time of Flourens' early experiments, physiologists and clinicians have concerned themselves with the relations between labyrinthine or vestibular nerve phenomena, and those dependent on pure cerebellar activity. Comparisons and parallels have been drawn and the extraordinary similarity in some instances and even the identity between the results of experiments on the vestibular nerve apparatus and the cerebellum have been shown by many competent investigators. The decision whether vertigo and nystagmus are cerebellar or vestibular symptoms must be largely determined by a thorough study of each case.

From the position of the cerebellum and its peduncles, the cranial nerves and particularly those from the fifth to the twelfth are frequently implicated in cerebellar affections, the complex resulting being compounded of true cerebellar symptoms and those referable to such of these nerves as may be involved. To this type of case Stewart and Holmes have given the name of "extracerebellar." The well-known and much-studied affections of the cerebellopontile angle belong in this category, although extracerebellar symptoms are not limited to the phenomena of lesions of this angle.

Besides the cranial nerves, the nuclei and the tracts of the neuraxis are not infrequently invaded in cerebellar lesions, and we have still another combination of symptoms, cerebelloneuraxial, which requires close scrutiny in the process of diagnosis.

The clinician is indebted to Babinski for the fixation of his attention on cerebellar asynergy. Ferrier, however, recognized the fact that synergic control was the particular rôle of the cerebellum. Discussing the mechanism of cerebellar coordination and the relative development of the cerebellum, he says:[1]

> Every form of active muscular exertion necessitates the simultaneous cooperation of an immense assemblage of synergic movements throughout the body to secure steadiness and maintain the general equilibrium; and on the hypothesis that the cerebellum is the center of these unconscious adjustments we would expect the cerebellum to be developed in proportion to the variety and complexity of the motor activities of which the animal is capable. The facts of comparative anatomy and development are entirely in harmony with this hypothesis.

Synergy or synergia is the power or faculty by which movements more or less complex, but functionally definite, are associated in a special act or acts. In a broad sense it is motor association, this association being carried out in movements of different parts of the same limb or in synchronous movements of the trunk and limbs, or of the head and trunk and limbs, etc.

Movements are mismeasured, giving dysmetry or hypermetry because the patient with cerebellar disease is unable motorially to associate the different elements of such movements. Adiadokocinesis, as illustrated for example by the impossibility of correctly and rapidly pronating and supinating the hand on the forearm, is due fundamentally to the inability to carry out fine motor associations of an antagonistic kind.

The method usually employed in clinical study or class instruction of demonstrating hypermetry is the well-known finger-to-nose test; for adiadokocinesis, partly flexing the forearm or forearms on the elbow and then rapidly pronating and supinating the hand, the movement being largely one from the wrist. Adiadokocinesis and hypermetry are both demonstrated by the rapid pronation and supination of the hand on the knee. Tremor is exemplified by the finger-to-nose test and by efforts to grasp an object or by writing. Hypermetry is shown by the finger which usually is able to touch the end of the nose overshooting to one side, or in the hand-knee test by the hand not keeping within the normal range of movement.

[*] On account of lack of space this paper has been abbreviated for The Journal. It will appear in full in the Transactions of the Section and in the authors' reprints.

[1] Ferrier, David: Functions of the Brain, Ed. 2, 1883, p. 200.

The phases of asynergy described as dysmetry or hypermetry are discoverable, however, in cerebellar cases in the abnormal attitude or movements of the head, in the bending of the trunk, in the abduction, sprawling, overstepping or understepping in walking, in the spreading of the limbs in standing and in much else that is done by the patient, and these dysmetric phenomena are frequently accompanied by tremor and adiadokocinesis, all of which are well defined in kinematographic observations.

KINEMATOGRAPHIC OBSERVATIONS

Our kinematographic investigations indicate the necessity of some revision of views both as regards the methods of describing and the intrinsic characteristics of cerebellar symptoms. Some new points in cerebellar symptomatology were elicited by these investigations.

The *gait* of a cerebellar patient in the majority of cases is chiefly trunkal. The trunk may go backward, or forward, forward and to one side, or simply to one side. The inclination may be total or partial. In every attempt on the part of the patient to walk, for example, the trunk from the first leans backward, forward or to one side, it being impossible for him to stand for any length of time in the erect posture. He may be able, however, for a short time to stand erect, or to walk either with the trunk erect or leaning, but even when this is possible he is likely soon to lurch forward or backward or to one side. In this type of case the movement of the trunk is predominant and forms the most impressive part of the picture, the legs seeming to act simply as props for the trunk. The trunk leads, and whatever way it goes, the legs follow. If, for example, the trunk leans forward and to the left, the swing of the left leg is shorter than that of the right, or if the trunk goes forward and to the right, the swing of the right leg is less than that of the left, the legs accommodating themselves to the movements of the trunk.

Our observations on pelvic girdle and shoulder girdle movements in locomotion, both when the patient is standing and when on all fours, are especially instructive. In some of the cases the asynergy is just as marked in the shoulder girdle as in the pelvic girdle. In those cases, however, in which the asynergy is more marked in the pelvic girdle, even if both girdles are affected, the gait is entirely different. Here the legs are held farther apart and the arms are nearly always held partly outstretched and semiflexed at the elbows. If the asynergy is shown alone in the pelvic girdle movements, the trunk assumes a different relation to the legs than in the cases just described. Here the trunk is held rigidly erect and the legs are pushed forward from the pelvis, giving the impression that the trunk goes after the legs. In the extreme pelvic girdle cases, it is impossible for the patient to walk without help, but when assisted, the trunk is very rigid, the legs being thrown out in almost any direction.

The cerebellar gait is often described as drunken or reeling, but from our observations, the gait is not like that of one who is drunk. A drunken man will reel in any direction, but he does this largely because of his mental, that is, of his cerebral reduction. A slightly drunken man simply reels forward or to one side, while one who is very drunk is unable even to stand up and any attempt on his part to do so brings on a sort of crumpling of the whole body. In such attempts the legs give way and the man falls because of this and not because his trunk forced him in a given direction. Besides, there is no attempt on the part of a drunken person to hold his arms outstretched for protection, whereas, the cerebellar patient is always careful as to how he walks, and knowing that he tends to stagger, makes efforts to obviate this and assumes as far as he can protective positions. He not only uses his cerebrum, which is largely out of commission in the case of the drunken man, but he even compensates in some degree for his cerebellar impairment by the forced or overuse of his cerebrum.

As has already been mentioned, when a cerebellar patient walks, the whole trunk may be projected in a given direction or one shoulder or one side may be moved more than the other, as for example, when a patient walks forward and to the left, in which case the left shoulder and left trunk are forward, the right side of the body lagging. The same thing will be true no matter what other position the body assumes, as when the patient changes to a sitting or standing from a recumbent posture. If the case is left-sided, then the left shoulder and trunk move first and more than the right; if right-sided, the right shoulder and trunk are more in the picture. If the case is bilateral or central, that is entirely trunkal, no difference in the movement of either side is detectable.

In the pelvic girdle cases when the patient attempts to get up from a recumbent posture and temporarily assumes in doing this a position on his hands and feet, the sway of the pelvis is very marked and may be chiefly to one side, but is nearly always to both sides. It is noticeable that in this position, the taking of which is one of the best methods of showing the relative degrees of pelvic girdle and shoulder girdle asynergy, if the pelvis only is involved, the trunk will not sway and whatever trunkal movements are present, are compensatory. These cases are much more common than those of the shoulder girdle. The methods thus indicated of demonstrating pelvic girdle and shoulder girdle asynergy have not, we think, been described before.

Turning now to some of our observations regarding *the movements of the limbs,* we are convinced that in testing for hypermetry, for example, it does not matter very much whether the finger goes beyond the nose, for many patients because of being repeatedly asked to do this learn to put their fingers to their noses quite well. The important thing is that if there is an asynergy of the upper limb when the patient attempts to place his finger to his nose, the movement being of wide range as when it starts with the hand on the knee, the whole arm including the shoulder takes part in the movement. The circle described by the hand is greater than it should be and in the majority of cases the movement is quicker than normal, although in some it is the contrary. In some cases when the patient is asked to put his finger to his nose the arm is swung inward; in some cases, outward and in some directly to the nose. The more marked the dysmetry the greater is the tendency for the sweep to be inward, that is, toward the body, and the greater is the involvement of the shoulder.

In testing hypermetry in the legs, if the patient is in a recumbent position and asked to put his heels to his knees or his heel to any point indicated, there is first an overflexion of the thigh on the abdomen and the heel nearly always overshoots the desired point. The nearer the pelvis is the point to be touched, the greater the sway of the leg, but the heel is usually placed on the desired point.

An equally good way to test hypermetry is by asking the patient to put the heel to the buttock. In this the movement is nearly always quick, the thighs are much more flexed on the abdomen than they should be and in the height of the excursion, with the heel approximating the buttock, there is always a to-and-fro sway of the limb, the degree of this depending on the severity of the symptom.

In testing for adiadokocinesis the attempts at alternate pronation and supination of the forearm and hand quickly show the degree of asynergy of the limbs. Adiadokocinesis may be tested in the lower limbs as well as the upper by alternate rotations or adductions and abductions. The defect is readily observed. The excessive movement may be either inward, outward, upward or downward in the upper limb and inward or outward in the lower limb. This is best brought out if only one side is involved, for then it is possible to compare the movements with those of the limbs of the other side. In some cases the movements are slow, but the important thing to look for is the overmovement.

In a case recently placed on record by one of us there was a *loss of emotional expression* on the right side of the face although the patient could use this side for every other purpose. The loss of emotional expression, while evident to ordinary observation, was emphasized by the kinematograph. In other cases, as for example, in paralysis agitans, disseminated sclerosis and focal lesions of the pons, we have been able to study changes in emotional expression more thoroughly than by the ordinary clinical method.

Not only can unilateral loss of emotional expression be exhibited, but a loss of all or almost all expression. One of our patients who could not be made to laugh or cry talked in a slow, monotonous, stupid manner with drooling of saliva. The moving pictures show not only the loss of emotional expression, but also the manner of speech. It is interesting that in this patient the movements of the limbs and body are of the same character as those of speech.

We believe in a true *cerebellar speech*, one type of which is shown in the patient described above. In another case which was for a long time in the nervous wards of the Philadelphia General Hospital the history was such as to indicate that the patient had had a hemorrhage into the anterosuperior portion of his cerebellum. He had most exquisite asynergy in his tongue, facial and laryngeal movements. His speech might be described as jerky and crackling. In this patient and in one other whom we recall, not only was the speech affected in the manner described, but mastication and deglutition were almost impossible because of the asynergy of the involved musculature.

In most of our cases examined kinematographically there were no asynergic *movements of the head and neck*. The head in these cases usually maintains the same plane as the trunk. In one case, however, shown in the series of pictures, the head is carried distinctly to one side. While the cases seemed to be relatively limited the fact that we have had a few speaks for the localization of movements of articulation, phonation, mastication and deglutition.

So far as our kinematographic observations are concerned, we showed, in one case, previously mentioned, of cerebellar agenesis, what we regard as true *asynergia of the eyeballs*. The eyes are never at rest. They move upward, downward, to either side, and in a rotary direction and combined, with the nodding of the head, give a furtive appearance, as if the patient were constantly dodging something. No two successive movements of the eyeballs are alike and it is with difficulty that the movements can be followed with the naked eye, although with the kinematograph this becomes easy.

In one of our patients vertical nystagmus was always present, and this occurred no matter in what direction the patient attempted to look. We believe because of the symptomatology that this patient had a lesion of the upper cervical cord and inferior cerebellar peduncles. We regard the nystagmus as due to involvement of the vestibulocerebellar apparatus, probably of the parts connecting the vestibular nuclei with the deep nuclei of the cerebellum.

In one of our patients in whom an exposure of the cerebellum was made, the cerebellum was incised to about the depth of half an inch at about the junction of the left superior semilunar lobe with the vermis. Directly after the operation and ever since, marked lateral jerkings of both eyeballs have been constant, but these have been more marked on the left. If the patient looks to the right the nystagmic movements are not so forcible, but on looking to the left they are strikingly exhibited. It is not that the left eyeball moves without the right, but that the excursion in the left eye is more marked than in the right and gives one the impression that the left eyeball alone is moving. It will be remembered that the incision was on the left. As these movements were not present before the operation it is apparent that they were the direct result of the incision into the cerebellum.

Babinski has described catalepsy as a new cerebellar symptom. In demonstrating this the patient is placed on his back, the thighs semiflexed on the abdomen, the legs on the thighs. After a few oscillations, according to Babinski, the legs become stationary and maintain their position for a longer than normal period. These phenomena in one patient were shown by Babinski by means of a moving picture at a meeting of the International Congress, 1913.

We found that most of our patients were too asynergic and asthenic to maintain their legs in the above-described position for more than a few moments. In other patients in whom the asynergy was not so marked, and particularly in the unilateral cases, we tested both the upper and lower limbs at the same time. The upper limbs in this test were first placed in a vertically extended position. The limbs on the affected side slowly drooped and reached the level of the body sooner than those of the unaffected side. In not a single patient did we find true catalepsy and we therefore do not look on it as a manifestation of pure cerebellar disease. In one of our patients, a very powerful man, one of our chief illustrations in the series of moving pictures, the man placed on his back was able to maintain his legs and arms in a set position—that of semiflexion of the lower limbs and vertical extension of the upper—but in this case there was no preliminary swaying and we regard the exhibition as pseudocataleptic and simply due to the great strength of the individual. The case was one in which the asynergic phenomena were expressed bilaterally, although the abnormal movements were more marked on the left and especially in the pelvic girdle.

CEREBELLAR LOCALIZATION—FOCAL SYMPTOMATOLOGY

In studying the focal symptomatology of cerebellar disease, hypermetry, adiadokocinesis and tremor at times indicate not only the presence of cerebellar asynergy, but give the clue to the part of the cerebellum most involved, as when these phenomena are most markedly exhibited in a special part of the body—the trunk, the upper or lower extremity, the head, face or eyes. These facts of localization are, we believe, emphasized by kinematographic investigations, as we have just tried to show.

The clinician soon finds that the focal symptomatology of cerebellar disease is not so easily comprehended as cerebral focal symptomatology. He recalls, however, from his experience, observations which have a bearing on this question. He has had cerebellar cases with marked unilaterality in their manifestations, indicating that one-half of this organ exerts its influence with marked predominance on one side of the body. In other cases, not on the whole numerous, ocular movements have been disordered in a way not explicable by limited lesions of parts of the brain other than cerebellum. In other instances, also not numerous, the speech of the patient is affected in a manner not to be explained merely by bulbar or cerebral involvement, while in many instances both ocular movements and speech disturbances are wanting. He has noted that in different cerebellar patients the disordered movements of the trunk differ from each other in ways which can be definitely discriminated. Shoulder girdle movements in one instance, and pelvic girdle movements in another, are more affected. The changes in emotional expression sometimes observed differ in different cases. The head takes a special attitude in a few cases; in many others this not occurring. Extraordinary combinations of abnormalities of movement may be discoverable on casual observation or elaborate investigation.

The cerebellum as a whole and all of its parts are concerned with the function of synergia. When, however, a particular part or parts of the body are the seat of abnormal motor phenomena of cerebellar origin, such manifestations are focal and more or less capable of localization. If these focal symptoms were arranged in tabular form, we would have a list something like the following:

Focal Symptoms Indicated by Localized Asynergic Movements:

Eye movements.
Attitude and movements of head.
Movements of jaw, face, tongue, larynx, etc.
(Disturbances of speech, emotional expression, etc.).
Position and movements of trunk.
Special movements of upper extremity.
(Disturbances in fine movements including writing).
Movements of trunk and upper extremity (shoulder-girdle movements).
Special movements of lower extremity.
Movements of trunk and lower extremity (pelvic-girdle movements).

CEREBELLAR LOCALIZATION—COMPARATIVE ANATOMY AND EXPERIMENTATION

Some of the results of embryologic and morphologic investigation of mammalian cerebella indicate the development and elaboration of function in this organ. Among those who have contributed work of great value in this direction we find some of the most distinguished names in the field of neuro-anatomy: Kölliker, Schwalbe, Elliot Smith, Bolk, Van Rynberk, Charnock Bradley and others. To the results of the investigations of some of these, Rothmann has appealed in corroboration of his own experimental and pathologic findings.

Studying the mammalian cerebellum from the lowest types to man, certain facts of paramount interest regarding the development of fissures, folia, lobules and lobes attract attention. The methods in which fissures appear, extend, recede and disappear and the horizontal and sagittal expansion of cerebellar substance go hand in hand, as in the development of the cerebrum with additions and intensifications of function.

In the lower mammals like the squirrel, the ox, the dog and the monkey, the cerebellum has a less marked subdivision into a middle lobe and lateral lobes than in man. Such subdivision appears and becomes more definite as the evolutionary series approaches man. Glancing, for example, at the dorsal aspect of a series of the cerebella of apes or their semidiagrammatic representation as given by Bolk, one deep somewhat anterior fissure usually called the *sulcus primarius* is uniformly observed traversing the entire width of the cerebellum, while above and below this are distinct fissures shallower and of varying lateral extent, only one, much more posterior than the primary fissure mentioned above, crossing the full width of the cerebellum. In the cerebella of these animals a vermis of moderate extent is distinctly to be seen in the posterior region of the cerebellum. In *Lemur albifrons* the deep transverse fissure is seen with shallower fissures anterior and posterior to it. In its posterior median portion is a well-defined middle lobe, to the right and left of which are lobes traversed by a short fissure with radiations. This intercrural fissure separates two crura or limbs of a cerebellar lobe, the *crus primum* and *crus secundum*. Many of the references to the experiments on lower animals, as on dogs and monkeys, are to the effects produced by extirpation or irritation of these parts.

Bolk, Elliot Smith and Bradley have made schema of the mammalian cerebellum. Von Bechterew adapted the schema of Bolk so as to give a general view of the functions of the cerebellum (Fig. 1).

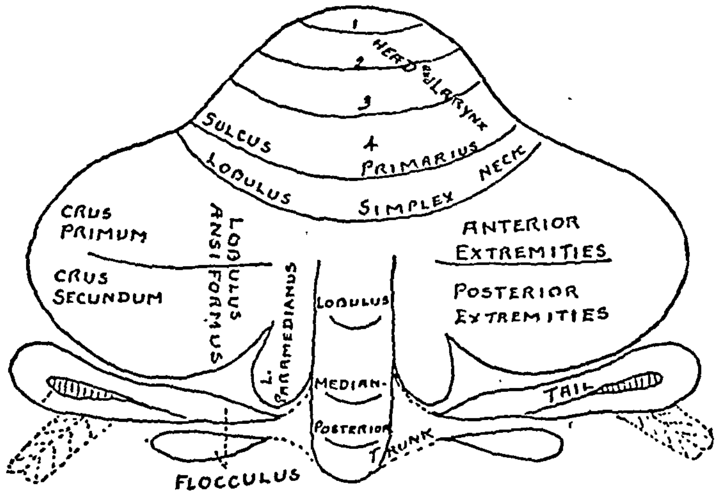

Fig. 1.—Bolk's schema of the mammalian cerebellum; on the left half the new anatomic names; on the right half the functions of special areas (Von Bechterew).

It is in the parts homologous in the human brain with the *crus primum* and its correlated vermis that the highly evolved synergic movements of the upper extremity and trunk appear to be represented, and in the *crus secundum* and its correlated median and paramedian regions the highly developed synergic movements of the lower extremity and trunk, those especially concerned with the maintenance of the erect position of man and his ability to perform complex synergic movements in this position.

In the anterior portion of the human cerebellum as in lower mammalia, movements more or less common to both them and to man—movements of the eyes, head, jaws, face and larynx—are represented, although this representation in man is of higher synergies than in lower animals. This anterior lobe is to be regarded more as a whole—as transverse or azygos—without so much reference to a separation into middle and lateral parts as has hitherto been considered essential, although the superior vermis and its wings may have subdivisions of their general representation.

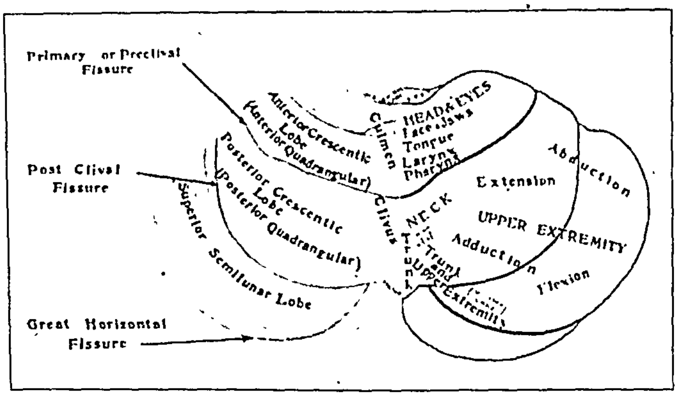

Fig. 2.—Cerebellar localization; zones and centers of the superior surface of the cerebellum.

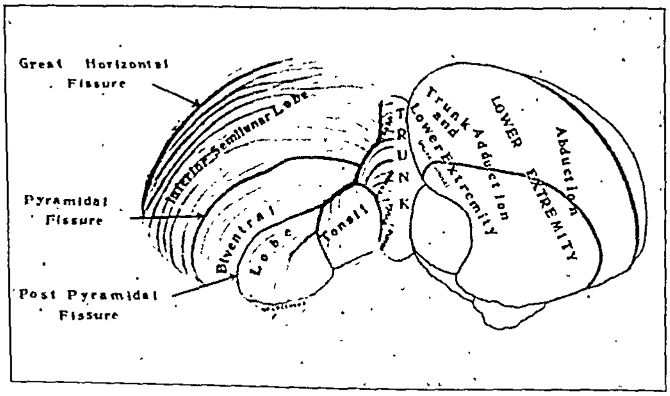

Fig. 3.—Cerebellar localization; zones and centers of the inferior surface of the cerebellum.

The demand for a complex representation of movements which are complex and elaborate has led to the tremendous development in man of that subdivision of the cerebellum which is posterior to the primary fissure.

The localization of cerebellar function and the abnormal phenomena produced by limited cerebellar lesions have been chiefly investigated by extirpation and electrical irritation. The extirpation experiments have been of varying character, sometimes decapsulation of a whole lateral lobe or of this and the vermis or of the vermis alone; and sometimes by extirpation of small areas in definite parts of the cerebellum as in the anterior lobe, in the *crus primum, crus secundum,* the posteriomedian lobe or inferior vermis, or the paramedian region.

The electrical-excitation experiments have been performed on carefully selected spots and areas of the cerebellar cortex and some observers have endeavored to isolate their irritation experiments to the deep nuclei of the cerebellum. We are in accord with Rothmann in our belief that the cerebellar cortex is excitable to the electric current, a fact which was long ago demonstrated by Ferrier and which we have confirmed in one case on a human subject. A stronger or longer-continued current seems to be required to bring about movements in the case of the cerebellar cortex than in that of the cerebral cortex, but such excitation is possible and can be more or less circumscribed.

In another communication, reviewing the neurologic contributions to the Seventeenth International Congress, one of us[2] has summarized the findings indicating special localizations by recent cerebellar experimentalists (Rothman, Prus, Adamkiewicz, Pagano, Bolk, Van Rynberk, Luna, Katzenstein and Rothmann, Bárány, and others). It is not always easy or perhaps possible to homologize the parts isolated in experiments on lower animals with divisions and subdivisions of the human cerebellum, and clinical contributions supported by necropsies have not yet been sufficiently numerous and exact to furnish absolutely dependable corroborations of the work in experimental physiology. Based on our studies of the literature of cerebellar embryology, comparative anatomy, experimentation and clinicopathology and on the results of our direct and kinematographic clinical observations, these studies in a few instances being reinforced by operations and necropsies, we have attempted a tentative schema of localization in the human cerebellar cortex (Figs. 2 and 3). It must be understood that this is regarded by us not only as tentative, but in some particulars as merely suggestive. One cannot with the same accuracy and certainty as in the case of the cerebral cortex indicate this or that region of the cerebellar cortex as exclusively concerned with the movements of the eyes, head, face, jaws, trunk, extremities or special parts of the limbs. The important fact that the cerebellum as a whole and in subdivision is concerned with synergy indicates that movements in which various parts of the body are at the same time concerned cannot be fully represented by a center or area for movements of one of these parts. The eyes may move to the right or left, or up or down without any association with other movements, but on the other hand, the eyes may move synergically with the head or with the head and trunk or with the head and trunk and limbs. The trunk may be bent forward or backward or twisted to the right or left with little or no association with movements of the extremities, but such comparatively simple trunkal movements are not the rule in bodily actions. The rôle played by the cerebellum has its best exemplifications in such acts as advancing and retiring in the erect position or in the performance of complex movements strength of the individual. The case was one in which the asynergic phenomena were expressed bilaterally, although the abnormal movements were more marked on the left and especially in the pelvic girdle.

---

CEREBELLAR LOCALIZATION—FOCAL SYMPTOMATOLOGY

In studying the focal symptomatology of cerebellar disease, hypermetry, adiadokocinesis and tremor at times indicate not only the presence of cerebellar asynergy, but give the clue to the part of the cerebellum most involved, as when these phenomena are most markedly exhibited in a special part of the body—the trunk, the upper or lower extremity, the head, face or eyes. These facts of localization are, we believe, emphasized by kinematographic investigations, as we have just tried to show.

The clinician soon finds that the focal symptomatology of cerebellar disease is not so easily comprehended as cerebral focal symptomatology. He recalls, however, from his experience, observations which have a bearing on this question. He has had cerebellar cases with marked unilaterality in their manifestations, indicating that one-half of this organ exerts its influence with marked predominance on one side of the body. In other cases, not on the whole numerous, ocular movements have been disordered in a way not explicable by limited lesions of parts of the brain other than cerebellum. In other instances, also not numerous, the speech of the patient is affected in a manner not to be explained merely by bulbar or cerebral involvement, while in many instances both ocular movements and speech disturbances are wanting. He has noted that in different cerebellar patients the disordered movements of the trunk differ from each other in ways which can be definitely discriminated. Shoulder girdle movements in one instance, and pelvic girdle movements in another, are more affected. The changes in emotional expression sometimes observed differ in different cases. The head takes a special attitude in a few cases; in many others this not occurring. Extraordinary combinations of abnormalities of movement may be discoverable on casual observation or elaborate investigation.

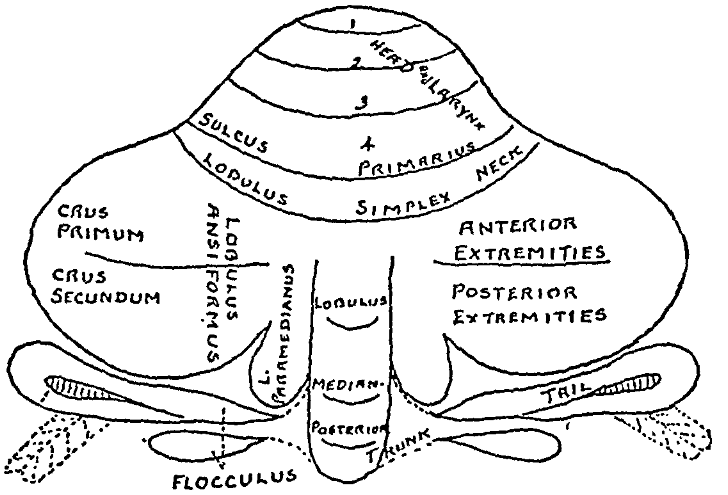

Fig. 1.—Bolk's schema of the mammalian cerebellum; on the left half the new anatomic names; on the right half the functions of special areas (Von Bechterew).

The cerebellum as a whole and all of its parts are concerned with the function of synergia. When, however, a particular part or parts of the body are the seat of abnormal motor phenomena of cerebellar origin, such manifestations are focal and more or less capable of localization. If these focal symptoms were arranged in tabular form, we would have a list something like the following:

Focal Symptoms Indicated by Localized Asynergic Movements:

Eye movements.
Attitude and movements of head.
Movements of jaw, face, tongue, larynx, etc.
 (Disturbances of speech, emotional expression, etc.).
Position and movements of trunk.
Special movements of upper extremity.
 (Disturbances in fine movements including writing).
Movements of trunk and upper extremity (shoulder-girdle movements).
Special movements of lower extremity.
Movements of trunk and lower extremity (pelvic-girdle movements).

CEREBELLAR LOCALIZATION—COMPARATIVE ANATOMY AND EXPERIMENTATION

Some of the results of embryologic and morphologic investigation of mammalian cerebella indicate the development and elaboration of function in this organ. Among those who have contributed work of great value in this direction we find some of the most distinguished names in the field of neuro-anatomy: Kölliker, Schwalbe, Elliot Smith, Bolk, Van Rynberk, Charnock Bradley and others. To the results of the investigations of some of these, Rothmann has appealed in corroboration of his own experimental and pathologic findings.

Studying the mammalian cerebellum from the lowest types to man, certain facts of paramount interest regarding the development of fissures, folia, lobules and lobes attract attention. The methods in which fissures appear, extend, recede and disappear and the horizontal and sagittal expansion of cerebellar substance go hand in hand, as in the development of the cerebrum with additions and intensifications of function.

In the lower mammals like the squirrel, the ox, the dog and the monkey, the cerebellum has a less marked subdivision into a middle lobe and lateral lobes than in man. Such subdivision appears and becomes more definite as the evolutionary series approaches man. Glancing, for example, at the dorsal aspect of a series of the cerebella of apes or their semidiagrammatic representation as given by Bolk, one deep somewhat anterior fissure usually called the *sulcus primarius* is uniformly observed traversing the entire width of the cerebellum, while above and below this are distinct fissures shallower and of varying lateral extent, only one, much more posterior than the primary fissure mentioned above, crossing the full width of the cerebellum. In the cerebella of these animals a vermis of moderate extent is distinctly to be seen in the posterior region of the cerebellum. In *Lemur albifrons* the deep transverse fissure is seen with shallower fissures anterior and posterior to it. In its posterior median portion is a well-defined middle lobe, to the right and left of which are lobes traversed by a short fissure with radiations. This intercrural fissure separates two crura or limbs of a cerebellar lobe, the *crus primum* and *crus secundum*. Many of the references to the experiments on lower animals, as on dogs and monkeys, are to the effects produced by extirpation or irritation of these parts.

Bolk, Elliot Smith and Bradley have made schema of the mammalian cerebellum. Von Bechterew adapted the schema of Bolk so as to give a general view of the functions of the cerebellum (Fig. 1).

CARCINOMA, SYPHILIS, AND TUBERCULOSIS COEXISTENT IN THE SAME PATIENT

WITH REPORT OF A CASE

ELLIS KELLERT, M.D.
Resident Physician, Huntington Memorial Hospital, Cancer Commission of Harvard University
BOSTON

The occurrence of active tuberculosis with carcinoma or of carcinoma with syphilis in the same patient is occasionally observed. We find reported in the literature many cases of lupus associated with epithelioma, and also of pulmonary tuberculosis with cancer involving the same, or some other organ, as the stomach, intestine, or liver. Much more infrequently do we see cases of carcinoma and syphilis in the one individual. The majority of these are patients in whom a malignant growth occurred at the site of leukoplakial patches. Cancer associated with syphilitic lesions of the central nervous system is not of common occurrence. The association, however, of carcinoma, tuberculosis and syphilis, each involving primarily a different organ in the same patient is apparently extremely rare. Such an occurrence is not mentioned in any of the standard works on pathology or carcinoma, and a careful search through the literature has failed to reveal a single recorded instance of a combination of these three diseases. Therefore, the following case, in which all three conditions were demonstrated during life and confirmed at the postmortem examination, is thought to be of sufficient interest to place on record.

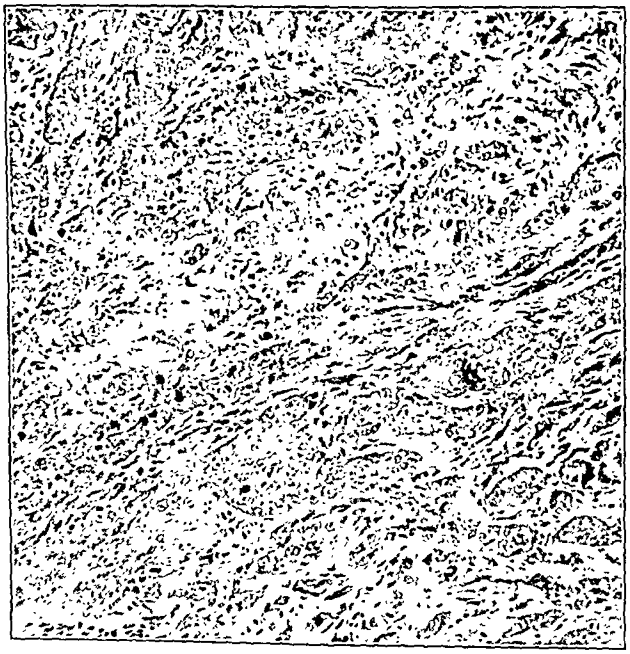

Fig. 1.—Section of tumor in pharynx. From a photomicrograph (×135)

REPORT OF CASE

Mrs. O. M. J. (Case No. C. 1. 13. 44) aged 39, housewife, born in Ireland, was referred by Dr. N. Faxon of Stoughton to the Huntington Memorial Hospital, Sept. 27, 1913, complaining chiefly of difficulty in swallowing.

Present Illness.—In July, 1910, shortly after her first confinement, patient noticed that her knees became weak. She was able to stand and walk, but had great difficulty in going up or down stairs. This condition persisted until after her second confinement in September, 1912, when she became troubled by a "sort of numb, tired feeling" in the back of her head. This came on when she sat up for the first time after parturition, lasted for three months, and then passed into the spine and rectum, where there was severe pain, frequently during the entire day. Two months ago her throat began to "fill up" and she was unable to swallow. Local treatments by a specialist afforded temporary relief. Patient states that she occasionally has chills. For the past six months she has been nauseated in the morning, but seldom vomits. Has had cough and expectoration for the past two months. Her appetite was very good until the throat symptoms appeared. Bowels have been regular, no bladder symptoms. She has lost greatly in weight.

Past History.—Patient had measles, mumps and whooping-cough during childhood, typhoid fever and malaria in later life. Menstrual history is negative, except that the periods ceased after her first injection of salvarsan. She married at the age of 33 and had two children, both alive and well, one instrumental and the other a normal delivery. Does not use alcohol and denies venereal history.

Family History.—The patient's father died of blood-poisoning, but no information was afforded concerning recent injury or other cause. Mother died of asthma. Has one sister who is alive and well. No history of tuberculosis or tumor in the family.

Physical Examination.—The patient is a slightly built, emaciated, white female adult of brunette type. The skin and mucous membranes are pale. The forehead is prominent, the nose slightly depressed. The pupils are moderately contracted and react to accommodation, but not to light. The tongue protrudes mesially, and is red at the tip and margins. The papillae are prominent. The upper teeth are false. The pharynx is deeply injected and on the posterior wall above the level of the epiglottis is seen a rounded elevated nodule approximately 0.5 cm. in diameter. Beneath this, and extending downward to the left as far as the eye can see, is an ulcer, irregular in outline, and with elevated edges. The base is covered with a grayish-yellow discharge and projecting masses of reddish tissue can be seen. On the right side of the neck, beneath the ear, is an oval-shaped firm mass 3 by 2 cm. It is adherent to the tissues beneath it. The cervical lymph-nodes are readily palpable.

The thorax is symmetrical; the ribs, clavicles and sternum are prominent. Tactile fremitus is increased over the left chest. The area of cardiac dulness is within normal limits. The apex is heard best in the fifth interspace, 8 cm. from the midsternal line. The sounds are normal. The respiratory sounds are increased throughout the chest, particularly on the left side. Posteriorly, they are bronchovesicular in character and an occasional dry râle is heard.

The abdomen is depressed, linea albicantes are present. There is no increase in the area of hepatic or splenic dulness. The kidneys are both palpable, the right somewhat movable. The inguinal lymph-nodes are readily palpable.

The knee-jerks are absent. There is no ankle-clonus, no Babinski, although the right toe is slightly suggestive. Plantar reflexes are present. The umbilical reflex is absent. The patient cannot walk unassisted. The gait is spastic and the foot is brought down flatly. The toes point outward. On standing still, she sways slightly and on closing the eyes, topples over. The pulse is rapid, regular, of low tension and vessel-wall soft.

July 19, blood-serum was obtained for a Wassermann test by her physician, Dr. N. Faxon, and a positive report was returned. July 21, 0.4 gm. of salvarsan was given intravenously and on August 15, 0.6 gm. of neosalvarsan. She reacted strongly to these injections with chills and increased temperature. The administration of potassium iodid was then begun and continued up to the time of her entrance into the hospital.

Oct. 1, 1913, a fragment of tissue removed from the throat was reported carcinoma. A Wassermann test on the blood-serum was negative. A roentgenogram of the chest showed a picture consistent with pulmonary tuberculosis. Soon afterward, acid-fast bacilli, morphologically tubercle bacilli, in large numbers were found in the sputum. Her blood-pressure varied from 80 to 95 (Tycos). The urine was not remarkable. The blood on entrance contained 12,200 white cells, 5,300,000 red cells and 90 per cent. hemoglobin. Later the white blood-cells rose to 16,800 and on October 28 dropped to 10,200 and hemoglobin to 80 per cent.

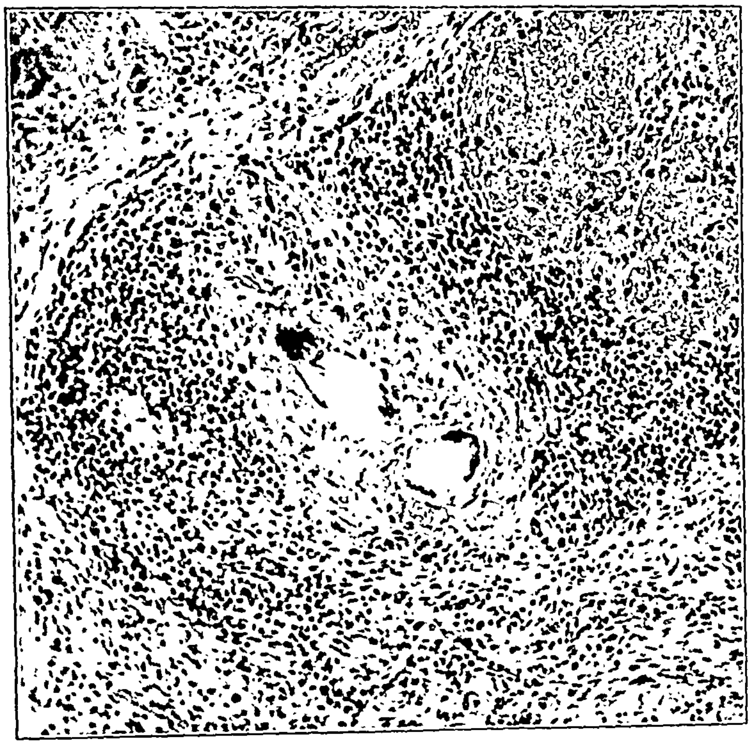

Fig. 2.—Section of tumor and tuberculous tissue from right side of neck. From a photomicrograph (X 135).

During the first part of her stay in the hospital, she improved slightly, after which her condition became progressively worse. The pulse varied between 120 and 130, the respiration from 30 to 36. The temperature ranged from 98 F. a. m. to 102 F. p. m., occasionally being so low as 97 F. in the morning and reaching 103 F. in the afternoon. Death occurred Nov. 13, 1913, preceded by several days of great weakness, increased difficulty in swallowing and cyanosis.

Post-Mortem Examination (by Drs. E. E. Tyzzer and E. Kellert).—Body length, 157 cm. Body is that of a woman, slender, well developed and markedly emaciated. Rigor mortis is present. There is a moderate degree of lividity over the posterior aspect of the body. At the anal orifice is a mass of reddish tissue 1 cm. in diameter covered with epithelium. There is a very slight degree of edema about the ankles. The outer aspect of the forearm shows a rounded scar measuring 1 cm. in diameter. The chest is depressed on both sides near the upper sternal region and the sternum shows marked bulging outward.

Peritoneal Cavity: Abdominal wall measures 3 or 4 mm. in thickness. The peritoneum is smooth. There are adhesions between the lower surface of the spleen and the transverse colon. The abdominal viscera are displaced downward. The transverse colon extends into the pelvis and is bent S-shaped on itself. The appendix is negative.

Pleural Cavities: There are numerous adhesions over the entire surface of the right lung. The left pleural cavity contains approximately 50 c.c. of yellowish-red fluid.

Heart: Weight, 240 gm. The myocardium is normal in color and consistency. The mitral valve presents several firm and non-calcified thickenings at the free edge. The coronaries are normal. The intima of the ascending aorta is smooth and without lesion.

Lungs: They are voluminous and do not collapse when chest is opened. In the posterior portion of the right lung are numerous small nodules of opaque tissue measuring 2 mm. in diameter. The smaller ones are slightly translucent. At the apex is a cavity 5 by 4 by 3 cm., which contains a thick grayish mucopurulent material. The walls are smooth and contain irregular branching bridges and trabeculae. The inferior left lobe presents, on cross-section, nodules similar to those above described. Many of these nodules are confluent and form irregular masses of opaque grayish tissue. The bronchial lymph-nodes are deeply pigmented and non-calcified.

Gastro-Intestinal Tract: In the median portion of the small intestine are two ulcerations of rounded outline. The larger measures 2 cm. in transverse diameter and 1.5 cm. longitudinally. The mucosa at the edge is elevated and irregular. On the serous surface of the intestine are minute translucent areas. The stomach and large intestine are negative.

Spleen: Weight, 118 gm. The capsule shows very minute translucent elevations. Cut surface is light-red. The trabeculae are prominent and the follicles indistinguishable. Several opaque nodules, some measuring over 1 mm. in diameter, are present.

Pancreas: Normal in size, color and consistency.

Liver: Weight, 1,180 gm. The capsule is smooth. Cut surface is of a dull chocolate-brown; the markings are not prominent. At one point there is an opalescent mass 3 mm. in diameter. The gall-bladder and bile-ducts are negative.

Adrenals: Normal in appearance.

Kidneys: Combined weight, 250 gm. The capsule strips readily, exposing a slightly torn surface. The medulla is redder than the cortex, which is pale brownish-red.

Bladder: At the neck of the bladder is an area containing greatly dilated blood-vessels and producing a bluish-red discoloration. The genitalia are not remarkable.

Aorta: Smooth appearance throughout. The retroperitoneal mesenteric lymph-glands are considerably enlarged and reddened and, in some of these, opaque areas are to be seen.

Organs of Neck: In the posterior and left lateral wall of the pharynx is an ulceration measuring 4 by 3.5 cm. The base is irregular and covered with a pale grayish exudate mingled with reddish granular elevations. Lower down, there is a small rounded mass 0.7 by 0.5 cm. and elevated 0.3 cm., also smaller translucent nodules from 2 to 4 mm. in diameter.

Bone-Marrow: Dark brownish-red and moderately firm in consistency.

Head: The frontal eminence and occipital protuberance are unusually prominent. The anterior portion of the calvarium is normal, but somewhat thick posteriorly. The base of the skull is negative.

Brain and Cord: Report by department of neuropathology No. N.-13-96. The brain weighs 1,324 gm. It is generally brachycephalic in type. The pia of the vertex is cloudy, and the pial vessels considerably injected throughout. The convolutions are fairly simple in pattern. There is no gaping of the sulci and no gross cortical lesions. The vessels of the circle of Willis show very slight stiffening, but no atheroma. One centimeter frontal section through the cerebrum and cerebellum show the corona radiata small in area. No gross lesions, except a suggestion of slight sclerosis of the arteries of the lenticular nuclei. The cord, on gross inspection, shows yellowing of the posterior columns. Sections from the cervical, dorsal and lumbar levels of the cord show a marked degeneration of the columns of Goll and Burdach. The process is more marked in the lower than in the cervical region. The posterior roots appearing in the section are almost entirely unstained. The blood-vessels, especially the arteries, show considerable thickening, particularly of the intima. There is slight loss of cells in the column of Clark. The lesion is typical of tabes dorsalis.

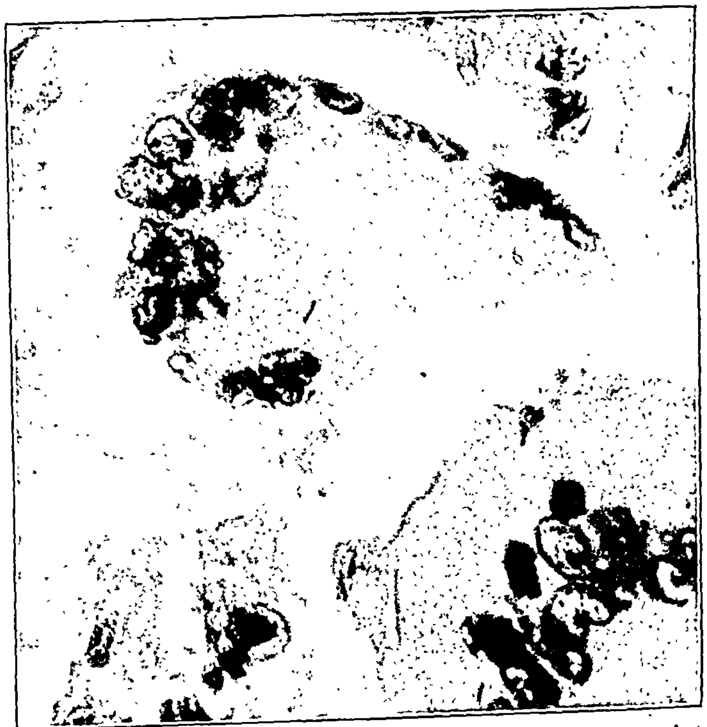

Fig. 3.—Section from tubercle shown in Figure 2. From a photomicrograph (X 1,000). Note giant cell containing tubercle bacilli.

Anatomic Diagnoses: Pulmonary tuberculosis with cavity formation; carcinoma of pharynx with metastasis to cervical lymph-node; tuberculous pleuritis with effusions; tuberculosis of lymph-node; tuberculosis of pharynx; edema of lungs; tabes dorsalis; tuberculous ulcers of small intestine; marked emaciation; external hemorrhoid; slight edema of feet.

Histology.—Pharyngeal Ulceration: Sections show an ulcerated surface covered with necrotic tissue, fibrin and bacteria. Directly beneath the ulcer are large closely packed masses of tumor epithelium which extend inward, where the tumor appears to be subdivided into smaller masses or isolated cells surrounded by dense fibrous tissue. In many of the larger masses are foci composed of pink-stained, swollen epithelial cells which are evidently necrotic. The tumor cells are large, irregularly rounded or polyhedral in shape and present a moderate amount of faint pink-staining cytoplasm. The nuclei vary considerably in size and shape but in general are large, rounded, vesicular and show one or more nucleoli or chromatic masses. Mitotic figures are present, but not numerous. The stroma appears, for the most part, dense in character and presents spindle-shaped connective-tissue cells, rare eosinophil and lymphoid cells. Blood-filled capillaries are numerous.

Enlarged Cervical Lymph-Node: A layer of tumor tissue is found enclosing the caseous interior of the mass and the whole more or less encapsulated. The capsule consists of dense fibrous and fat tissue containing nerves. Between the capsule and layer of tumor tissue is a narrow margin of lymphoidal tissue, dilated lymphatic spaces and areas of tuberculous tissue. The lymph spaces are surrounded by a supporting tissue containing but few cells. The tumor epithelium is closely associated with the tubercles, but there is no admixture of the two. The tubercles are distributed over the outer surface of the tumor tissue. Acid-fast bacilli are present.

Heart: The muscle fibers contain a moderate amount of brownish pigment situated about the nucleus.

Aorta: There is a diffuse thickening of the intima, but no calcareous deposits.

Lung: There are extensive areas of edema and caseation and many tubercles, both miliary and confluent. Some of the larger areas are surrounded by a thick connective-tissue capsule containing tuberculous tissue, frequently with giant cells. There is no calcification present. The alveoli surrounding the tuberculous tissue are filled with masses of fibrin and desquamated endothelial cells. There are numerous acid-fast bacilli present.

Small Intestine: The ulcerations involve the entire thickness of the intestinal wall. The superficial layers are composed entirely of necrotic and inflammatory tissue. Beneath this are tubercles and fragments of smooth muscle. There are very few giant cells present. The capillaries are dilated and filled with red blood-cells. Large numbers of acid-fast bacilli are present.

Liver: The hepatic cells about the central veins are in various stages of degeneration. Many are necrotic or absent. There are numerous polymorphonuclear leukocytes present. About the periphery of these areas of necrosis are columns of normal-appearing liver cells and there is a moderate degree of replacement of the hepatic tissue with fat. The sinusoids in the necrotic portions are dilated with blood-cells. There are large numbers of small tubercular areas scattered throughout the parenchyma.

Spleen: A few similar tubercles are present.

Kidney: There is a slight degree of degeneration of the tubular epithelium, and a few of the tubules contain casts.

Uterus: An occasional small blood-vessel in the myometrium shows hyaline changes, and there is moderate atrophy of the endometrium.

Lymph-Nodes: Miliary tubercles are present. The sinuses are frequently dilated and filled with desquamated endothelial cells, some of which are phagocytic for red blood-cells.

Bone-Marrow: It is not remarkable.

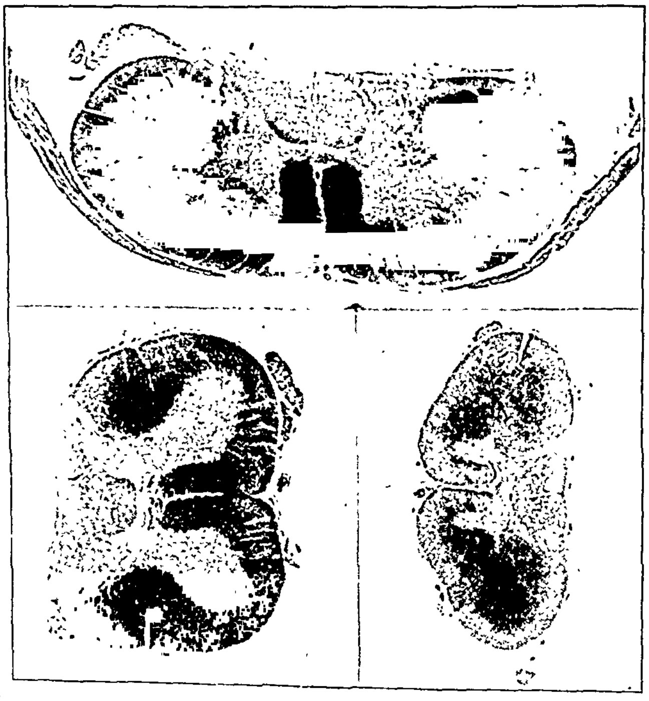

Fig. 4.—Section of spinal cord at varying levels showing degeneration of posterior columns. From a photomicrograph (× 6).

This patient, therefore, presented three distinct diseases, each involving primarily, though not confined to, a different organ—an invasive tumor primary in the pharynx with metastasis to a cervical lymph-node; an extensive bilateral pulmonary tuberculosis, and tabes dorsalis. The lesions are typical for each of these three, any one of which would ordinarily be regarded as a major disease. The origin of the syphilitic infection is somewhat obscure. The patient, an intelligent woman, most emphatically denied a venereal history. She had given birth to two normal and healthy children and did not have a miscarriage or abortion. It is stated in the family history that her father died of blood-poisoning, but further details could not be obtained. The peculiar shape of the head, the prominent frontal region, and the somewhat depressed bridge of the nose, slightly suggest congenital syphilis.

Although comparatively few cases of combined carcinoma and tuberculosis have been reported, it is doubtful if there exists between them any antagonism. Thus Bastedo,[1] who gives an excellent review of the literature, finds that there is no specific favoritism or antagonism between the two diseases; that cancer is more common among those with latent tuberculosis than among those at the cancer period of life. The common age for cancer is not the age for active tuberculosis. Moak,[2] in looking over the records of the Bender Hygienic Laboratory, found carcinoma present in 6.6 per cent. of active tuberculous cases. This percentage is rather higher than that of other observers. Lubarsch[3] found cancer present in 4.4 per cent. of active tuberculosis, and McCaskey[4] in 1.4 per cent. The latter notes that retrogression of cancer has occurred after the injection of tuberculin. Patients dying of cancer not infrequently show old scars or calcification in the apices, indicating healed tuberculosis.

An occasional observation has been made in which it was thought that a tuberculous ulcer preceded a malignant growth. Such cases have been reported, but observations of the combined conditions, cancer and tuberculosis, as of the hand (Lapeyre[5]), esophagus (Weyeneth[6]), (Corduo[7]), larynx (Beale[8]), and intestine (Dixon, Smith and Fox[9]), have been more common. Lupus and carcinoma are frequently associated, but the pathologic processes involved, in which groups of epithelial cells are isolated by the "frequent cicatrizations, place these lesions in a class by themselves" according to Bastedo.[1]

Certain observers have concluded that the tubercle bacillus and its toxins are concerned in the etiology of cancer, but the relationship is not clearly demonstrated. Dixon, Smith, and Fox,[9] after animal experimentation, convinced themselves that the tubercle bacillus and its products could stimulate epithelial structures. While it is true that an epithelial hyperplasia can be brought about by the tubercle bacillus and its products, yet there is no evidence to show that it can produce an invasive tumor. If this were true, we should expect to find cancer much more frequently associated with tuberculosis, and more common at an earlier age. Roger Williams[10] pointed out that as cancer increased, phthisis decreased.

[9] Dixon, Smith and Fox: On Cancer and Tuberculosis, Penn. Health Bull., Harrisburg, 1911, No. 24.

Syphilis is a fairly common disease and yet its combination with carcinoma is exceedingly rare. This is indicated in the statistics gathered by Williams. He mentions the case of Turenne, who syphilized his recently operated cases, hoping thereby to prevent a recurrence of the growth. Lang,[11] on the other hand, claims to have observed syphilitic infiltrations which became converted into malignant neoplasms. He believes that the toxins of syphilis may weaken the organism which is more readily attacked by tumor growth. He also believes that cutaneous syphilitic infiltrations form a favorable soil for tubercle bacilli. We have found relatively few cancer patients who give a specific history, and Wassermann tests on their blood-serum but seldom give a positive reaction. This has been our experience at the Huntington Hospital, although varying percentages have been claimed at different clinics. Fox[12] reports a large series of cases with negative reactions. Many cases occur in which a malignant growth appears to have its origin in areas of leukoplakia.

It is always of interest to determine which lesion appeared first, and its influence on the development of subsequent affections, but only too often this is impossible. In the present case, it is apparent that the syphilitic infection must have occurred long before the active development of the other two conditions. The phthisis must have been a comparatively recent infection, for the history of loss of weight dated back but a few months. Throat symptoms developed about three months before death, so that the tumor was probably the last of the three diseases to appear.

Cases already reported and this one bring up the question of the occurrence of two or more active diseases in the same patient. We are inclined to think that it is to be found much more frequently than is commonly suspected. Thus typhoid and tuberculosis in combination are not uncommonly observed. Osler[13] found at necropsy, tuberculous lesions in 5 per cent. of typhoid cases. Yellow fever, dengue, malaria and amebiasis frequently coexist, so that individuals may harbor any two of the above infections. Recently, Strong, Tyzzer, and others[14] separated into two distinct diseases, oroya fever and verruca peruana, which had long been accepted as different manifestations of a single infection. It is not at all improbable that, in the tropics, many patients suffer from two and even three diseases. A short time ago a postmortem examination at this hospital in a case of myelogenous leukemia revealed also a tuberculous peritonitis with ascites. While the student is usually taught to make one diagnosis cover all the symptoms, the possibility of one or two other conditions being present must not be overlooked. In fact, it is unscientific not to consider the presence of more than one disease if the signs and symptoms indicate it.

In conclusion I wish to thank Dr. A. E. Taft for a thorough examination of the central nervous system and acknowledge my indebtedness to Dr. E. E. Tyzzer for assistance in the pathologic examination and report of the case.

THE RECONSTRUCTION OF THE NASAL SEPTUM AFTER THE SUBMUCOUS OPERATION*

JAMES A. BABBITT, M.D.
PHILADELPHIA

The reconstruction of the nasal septum after the submucous operation invites, first, a discussion from both the physiologic and the anatomic standpoint of the etiologic factors of nasal disturbance for which septal relief is indicated, and justification of the selection of surgical interference in the septum rather than other parts of the rhinopharyngeal tract; second, the adoption of surgical measures which will reasonably overcome the nasal disturbance with the least traumatic modification, and, third, the reestablishment of normal function in the part itself and the correction of the disturbed specialized function to which its displacement has contributed.

Succinctly stated, the consideration devolves on the three questions: For what may submucous resection be legitimately done? How can it most safely and simply be performed? How perfectly may the septum be reconstructed? Such reconstruction must include the anatomic rebuilding of a structure virtually razed to its foundation, the physiologic continuance of its general and specialized function and, finally, the relief in satisfactory measure from the conditions for which it was instituted.

The new partition must enable the septum to perform its part in the secretory, olfactory and respiratory activity of the nose, be anatomically strong enough to withstand reasonable subsequent trauma, preserve the alignment of the external nares and resist unfortunate sequelae.

Interesting results were reported by Anderson[1] from animal experimentation in obstructing the upper respiratory tract, proving that nasal obstruction leads to death or serious modification of vitality. It furthermore produces lowered resistance, predisposition to infection, local disease of the respiratory tract and associated cardiac, skin and pulmonary symptoms. He even produced asthma symptoms in the lower animals and found that reopening of the nose relieved them.

Consideration of this topic has been induced by a rather careful analysis of the procedures and subsequent results of about five hundred complete and partial submucous resections which I have performed, and by the rather fortunate opportunity, as will be later explained, of having obtained a septum specimen by secondary operation in which surgical and physiologic points of interest resulting from primary interference were well exhibited.

Obstinate catarrh, the neuroses of hay-fever or asthma, nasal stuffiness, eustachian tinnitus and sinus pressure are classical symptoms for which orthopedic correction of a deflected or nodular septum might be indicated. Here the personal equation of the specialist's examination must be severely eliminated, nor must the operator be influenced by the readiness and skill of his own preference for this operation. Surgeons subconsciously allow their minds to become focused on certain types of work, and it is difficult to escape the influence of this in their operative advice. The delicate decision as to the possibility of restoration in a middle turbinate showing early degeneration may frequently be the determining decision as to an operation on it or on the encroaching septum. A careful review of the physiology of these areas would indicate a preference for septal rather than turbinate interference.

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

[1] Anderson: Proc. A. L. R. and O., 1909.

Mentzenbaum[2] is of the opinion that the exenteration of the turbinate destroys an important vitalizing organ in the nose, but the splendid work of Mosher and others need not be discussed here.

Phillips[3] classifies cause of septal deformities as due to congenital malformations, arrested or excessive development of the facial bones and traumatic injury, with large majority in the latter, and quotes the importance of the progressive changes due to unrecognized childhood traumatism. It is doubtless due to the insidious development of such disturbance that the many conditions indicating septum operation are suddenly revealed and apparently almost spontaneously.

As Emerson says,[4] the patient consults not for the deflection, but for the conditions which have produced unequal ingress of air, hypertrophies, contact, insufficient drainage or active infection of the sinuses of the nasopharynx. He further enumerates asthma, headaches, aprosexia, disturbance of vision, aggressive otitis media, erysipelas from the infection of the erosions, eczema of lip, recurrent bronchitis, chronic nasal pharyngitis, redness of nose, aphonia, perversion of smell and taste, dyspepsia, mechanical obstruction and catarrh as symptomatic of septal deformity.

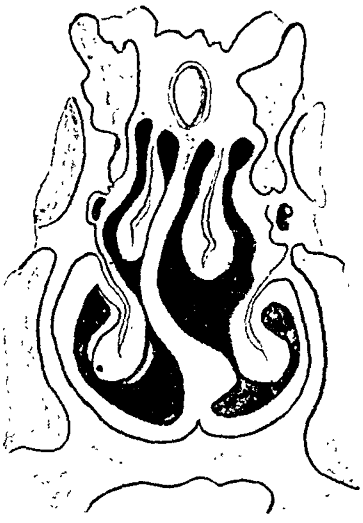

Fig. 1.—The most common type of deviation of the septum, presenting a common result of unrecognized traumatism.

To this might be added Bryant's[5] conclusions that epileptic seizures are more often due to reflex stimulus from the Schneiderian membrane to the fifth nerve than from other causes.

A most frequent indication for careful examination of the upper nasal cavity is a simple, indefinable stuffiness in that area, subjecting the patient to varying degrees of discomfort. Though indefinable, its degree of oppression is in sharp contrast to the unmeasured relief by removal of its cause. In a minor percentage of cases, hay-fever and asthma are relieved and occasionally entirely overcome if the obstruction be a sharp bulge or ridge constantly irritating the middle turbinate. Frontal and ethmoidal sinusitus, especially in those cases with recurrent attacks, have sometimes been eradicated by the correction of a markedly deformed septum. Hay-fever and asthmatic seizures, always problematic in prognosis, sometimes permanently change, and a most encouraging picture is seen in the return of normal luster to the mucous membrane.

As cited by Ballenger,[6] an irregularity of the septum *per se* should not indicate a submucous operation. The obstructive and irritative conditions present, combined with the symptoms enumerated above and obviously connected therewith, render the situation clear, though with one's tendency to become subconsciously focused in a certain type of work, possibly only a complete examination by an "all-around non-operative specialist"—if such hypothesis be possible—should determine in certain cases whether interference with the septum or the turbinate would be the more justifiable.

It is justifiable to associate ordinary postnasal catarrh with deformities in this area, especially those without adenoids, but with ridge, spur or deflection. Here must be carefully analyzed evidence of atrophic mucous membrane change, as the too-wide nasal cavity is one of dread. It might be suggested here that a careful subsequent review of patients some time after the septum operation should be instituted for possible sequelae of this sort.

A certain number of cases present a symptomatology of general defective metabolism—the stasis of gouty diathesis, sallow skin, foul breath and coated membranes. If these be associated with poor aeration of the upper respiratory passages, the obstructed nares may be a positive factor.

Richardson[7] has reviewed the connection of upper respiratory disturbance as a reflex of general body condition, counseling against undue haste for operation and early attention to dietary and hygienic reorganization, while Meyer reports treatment of ninety-three cases of nasal vasomotor disturbance by topical application for relief of dysmenorrhea.

Favorable result of septum replacement has been the experience of many of us in the relief of eustachian tinnitus, especially that associated with a posterior exostosis or hook-like projection of the vomer. The rationale of these improvements has been analyzed by many investigators, Leland[8] urging the freeing of the fossae of Rosenmüller of synechial or isolated patches of lymphoidal tissue at the onset of earache, and Norval Pierce, carrying the investigation further into the physical and physiologic factors involved in the diminished tympanic cavity, retraction and atrophic condition of the drum with ankylosis at the foot of the stapes. Changes in blood-supply with hyperemia and rarefaction of air explain the situation here and make septal replacement one of the positive elements in physiologic reconstruction.

Relief of eustachian catarrh and remodeling of the air-current with freedom through the tract of the pharyngeal tonsil area is a particularly favorable result. If we accept the theory suggested by Dr. Randall that the adenoid tonsil may be increased by obstructed nares, as well as the reverse, the change in rôle sometimes becomes explainable.

The extensive relation of the septal tract with eye affections forces a close connection of ophthalmologic and rhinologic fields. Hilcher[10] quotes a varied field of optic conditions—rebellious headache with eye pains, accommodative asthenopia with neuroretinitis, catarrhal conjunctivitis, recurring phlyctenular keratitis and dacryocystitis—as indicating an examination for nasal obstruction, while we receive constant reference of cases for study in this tract of involvement of the optic nerve.

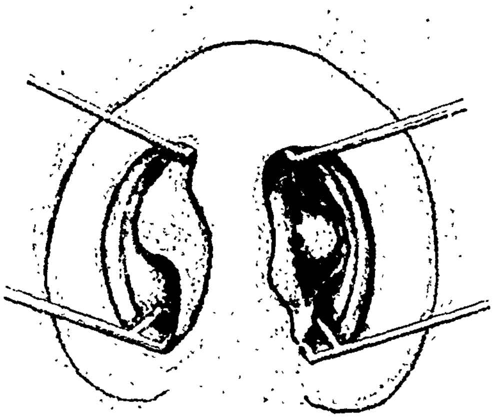

Fig. 2.—A type of deviation with a double compensatory vertical sweep.

Thus explained, the review of functional and pathologic lesions is pertinent to the topic, for their correction, as above stated, is essential to our propaganda of reconstruction.

Reverting now to the consideration of operative technic and the sequelae, positive and negative, certain localized phases of operative surgery in the rhinopharyngeal tract have become, within the past few years, most highly developed from an operative standpoint. The surgery of the nasal septum, the middle turbinate and ethmoidal sinuses, the pharyngeal orifice or the eustachian tube and the maxillary antrum have particularly shared in this progressive development—in fact, have become so specialized as to be associated with the name and procedure of certain eminent clinicians.

We may assume that those who skilfully and readily work beneath the perichondrium will elect this form of relief or its modification in preference to the varied procedures by saw, chisel, knife, electric burr and cautery.

Perhaps the most common type of deviation, presenting a frequent result of unrecognized traumatism, is shown in Figure 1, with a high bulging to the right and compensatory sweep below and overdevelopment of the ridge on the left. This simple form of deformity indicates but little explanation with the elaborate directions of Freer, Ballenger and others and the marvelous armamentarium provided therefor.

Figure 2 presents a type considerably more difficult, with a double compensatory vertical sweep, while in Figure 3, with both anterior and posterior nodular deformities, frequently invisible behind until the turbinates are well shrunken, is portrayed a type of disturbance most gratifying in its relief but frequently neglected or overlooked by the comparatively inexperienced nasal examiner.

As bewildering as the attempt at matching striped blades of oriental grass is the analysis and classification of irregular types of deviation. In the more intricate forms the assumption is justified that the skilful operator must be a mechanical expert, and I recall the ingenious suggestions of bevel saw and the button and ligature retention.

In my experience, perhaps the most successful nasal reconstruction resulted from three distinct operations: first, the removal of a vertical strip of cartilage, 3 or 4 mm. in width, from the anterior right nares to relieve the dislocated end of the triangular cartilage; then leaving a column which happened to remain in the median line, a formal submucous resection posteriorly on the left side for high compensatory bulge, and finally an external nasal operation which consisted in chiseling the nasal process of the superior maxillae on either side and swinging over an atrociously deformed external nose. The newly-constructed organ was of normal contour with evenly divided internal nares; there was restoration of the normal membrane, and a marked subsidence of eustachian symptoms which had well-nigh become organic.

In discussion of the operative technic, a successful replacement of the septum requires certain fundamental operative rules, and these are harmonious with the general principles of surgery: First, traumatism should be reduced to the minimum degree. This would mean an incision involving the simplest linear space. An increasing tendency in all general surgery would seem, that of allowing sufficient room for careful observation, and the suggestions of Yankauer, Butt[11] and others for continuing this incision well over the angle of the floor is compatible with safety. Such an incision should be thoroughly carried to the cartilage. To the experienced operator, the feel of the knife will be a guide to the depth of the incision, as slight grooving in the cartilage can do no harm and emphasizes the depth.

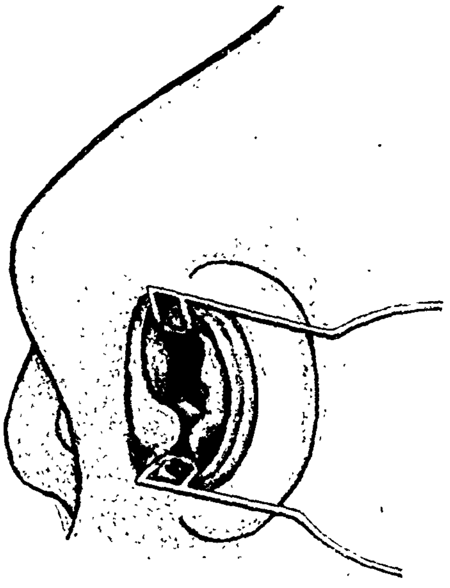

Fig. 3.—A type of deviation with both anterior and posterior nodular deformities.

---

[10] Hilcher: Northwest Med., 1909.

[11] Butt: Med. Times, Laryng., 1912.

The important circulatory channels, even though nasal anastomosis is most kindly, should be preserved and delicate nerve fibrils in the mucous membrane retained. The extent of operation, while only absolutely completed, as Freer[12] suggests, with all vestiges of bone deviation removed, should nevertheless not pass to the point of requiring unnecessary supportive splint pressure. A patient's recuperative condition must be considered, his limit of shock should be appreciated, the possible devitalizing of tissues from excessive topical shrinking, and anesthesia must be kept within bounds; while hemorrhage, apparently alarming, is really inconsequential. In comparison with other major operations, it cannot be of advantage to wound vessels and bony structure to the extent of causing copious bleeding.

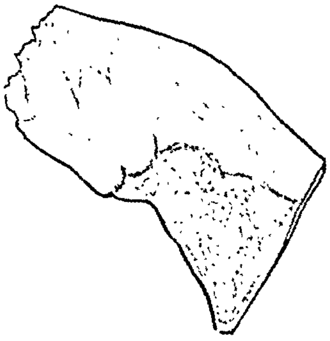

Fig. 4.—Portion of septum containing the segment from the posterior smooth end of which the section (Fig. 5) was taken.

In order to fulfil these conditions, I am inclined here to follow my custom in tonsillar operation and reduce the instrumentarium to the minimum. While most elaborate and ingenious instruments have been devised for meeting the varied forms of all angular exudancy and distortion, few septal operations really require more than half a dozen well-selected instruments, and this selection is designed to be compatible with the after-results required.

Freer's half-round-bladed septum knife, double-ended separator and reinforced edge retractor, Ballenger's swivel knife, Brünig's forceps for the perpendicular plate of the ethmoid and vomer, Schwartz' chisel for anterior ridge and Watson's small nasal speculum would complete an outfit and serve in everything but an exceptional case.

I am accustomed to use a simple septal knife, then a double-sided spatula of Freer, using the dull end to lift the membrane, then sliding the sharp end of the spatula obliquely through the cartilage, which I have not once perforated since the adoption of this method. The operation is then carried backward with gradual lifting of both perichondrium and periosteum, completing the *first* step as near to the floor and anterior and posterior extremities as possible, and leaving a smooth, ungrooved field.

It seems unimportant, with such carefully exposed field, whether Ballenger's swivel knife, or Brünig's forceps, or other means be used for removing triangular cartilage, perpendicular plate of the ethmoid and upper part of the vomer. Many authors have urged the rocking or bending of the septum. The adjacent portions of the vomer or ridge swing thus into place, if there be not too much redundancy of tissue. The small chisel for the anterior portion, and Brünig's forceps for the posterior will adequately lift out difficult portions, and it is important in the alignment of the septum, though perhaps not absolutely necessary, that the complete anterior projecting end should be removed, and particularly the deflected hook or exostosis posteriorly. Operatively, this procedure leaves a clean and comparatively uninjured operative field.

For the successful reconstruction of the septum, other points must be noted. The parts must be perfectly adjusted to secure primary coaptation and to prevent serous infiltration and hematoma. Angular incisions leave an extra granulating surface and a difficulty in the proximation of the folds. To prevent serous or hemorrhagic infiltration, a posterior point of drainage, as suggested by Butt and others, may advisably be made, well back between the folds of periosteum, as it can do no harm and stops a distressing complication with possible subsequent infection. The blood-vessels and delicate structures of the mucous membrane are then left in practically normal condition. The delay in secondary anastomoses is avoided if a minimum traumatism occurs.

Iglauer[13] suggests transplanting various substances to replace lost septal tissue, perforations, etc.—fat, skin, cartilage, bone, and other substances were investigated. This is not successful, hence, the importance of avoiding a gap and thus the necessity of replacing tissue, by leaving at least one perfect lateral surface of subsequent repair.

The operative sequelae of positive and negative type are nearly equal in number. The subjective relief of the patient, first, from his nasal stuffiness and associated irritation, and second the freedom from locked-up degenerated secretion are perhaps most consequential.

Alleviation of eye-strain and headache, relief of accompanying eustachian catarrh, and comfort to the nasopharynx from a remodeled air-current, are complements of the foregoing. The sinuses drain more freely and normally, their capacity as resonating chambers is improved, and slight colds do not irritate as before.

The work on the septum is capable of such careful analysis that accidents can in most cases be directly traced to faulty technic, which occurs here as in other forms of surgical interference.

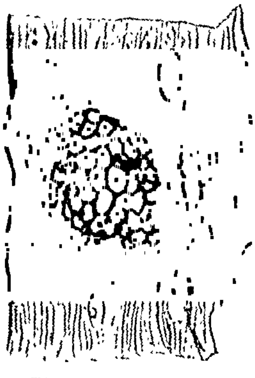

Fig. 5.—Slide showing fibrous tissue interspersed with vascular spaces, a certain amount of granular tissue and a well-formed nest of young, growing cartilage-cells.

Squamous epithelium replaces normal columnar epithelium in event of open cartilaginous granulation and gives rise to the constant irritating crusting, even without perforation. Perfect coaptation of the wound frequently leaves a scar which is almost invisible.

The surface of the mucous membrane again becomes abnormally thickened and perhaps permanently hypertrophied from the undue traumatic pressure of excessive or unguarded splints. Whether the bismuth paste of Beck, the Cargile or other membrane-covered splints of others, or simple bismuth rubber strips of gauze (demonstrated to me by Fisher) are used, the result is perhaps nearly equal, if undue pressure be avoided. One cannot accept the belief that a degenerated slough, even though protective, can fail to produce deterioration to mucous membrane when present. I have not found it advisable to leave the cavity without splints, but I have obtained excellent results by covering them with thin rubber tissue, which facilitates removal and seldom leaves excoriation.

[12] Freer, Otto T.: The Nasal Septum; A Description of the Author's Present Manner of Performing the Window Resection for Deflections, The Journal A. M. A., Sept. 30, 1905, p. 985.

[13] Iglauer: Tr. Proc. A. L. R. and O., 1913.

Packard[14] has reviewed the accidents and complications following operative procedures, quoting Lermoyez' classification as those of infectious, nervous and mechanical origin and in the nervous group widespread disturbance from simple neuralgias, vertigo, etc., even to asthma, laryngeal spasm and exophthalmic goiter.

It seems to have been the experience of those who have done considerable submucous work that it is best to adopt this procedure in practically every septal case. It is logical to assume that the preservation of a normal membrane is infinitely preferable to replacement of other tissue, and that a normal membrane with the slightest opening presents the smallest avenue for entrance of infection.

The most important point in diagnosis is to determine what is functional and what organic septal abnormality and, having determined the organic deviation, to form correct judgment as to the sequence of physiologic events in surrounding nasal and postnasal chambers.

Careful determination should be made as to the integrity of the mucous membrane, and if one side of the septum be sclerotic and thinned from previous erosion, as to whether the opposite membrane has sufficient vitality to form a safe retaining wall after operation.

After the suggestion of Roe,[15] the character of the external nose must be considered under these conditions: the firmness, the tip of the anterior nares, the degree of droop in the lateral folds, the type of fullness or aquilinity in external appearance, and the relation of the deflecting bulge to the outlets of the accessory sinuses.

Secondary injury to sinus or eustachian tube is usually due to locking infective secretions behind the deviation. I would make an especial plea for one particular procedure—beyond simple salt solution, antiseptics should be avoided in the nose at or near the operative period. In the Children's Hospital, it has been the custom to leave tonsils without interference after the operation, and the results have been uniformly as favorable as with other methods. The nasal secretion is naturally protective, and I deprecate the destruction of such secretion by either excessive washing or application of any active chemical solution whatever.

No traumatism, no undue pressure, complete removal of offending deviating structure, and avoidance of destruction of the natural resistance of the nose thus would seem to be the cardinal features in reconstructing a normal nose.

Believing that findings of any positive value should be recorded in contemporary literature for the sake of mutual benefit, I selected the topic of this paper in part as a vehicle to present the following rather interesting opportunity for study.

Figures 4 and 5 show a reproduction, first, of the septum containing the segment from the posterior smooth end of which the section was taken, and second, a reproduction of a slide showing fibrous tissue interspersed with vascular spaces, a certain amount of granular tissue and a well-formed nest of young growing cartilage-cells.

This particular patient presented himself about a year ago suffering from hay-fever neurosis of marked degree; examination of the posterior nasal cavity revealed too close propinquity of the septum and the lower portion of the middle turbinate. Submucous resection was advised and arranged for the following September and rather fortunately assistance was rendered by a careful student of septal surgery, Dr. Butt.

In separating the perichondrium posteriorly, a peculiar leathery resistance was found—a feeling resembling that of pressing on chamois-skin. This tissue doubled up somewhat but was fully and successfully separated, and a large segment of the cartilaginous septum removed. Comment was made by those engaged in the operation on the unusual folded feeling, but no other great difficulty was experienced even over the cartilaginous borders, and the inner surface of the perichondrium did not seem abnormal. The patient gave a history of having undergone a nasal operation by a specialist in western New York about two years previously, but he was somewhat doubtful about its nature.

The specimen, as portrayed in Figure 4, showed a smaller fibrous arc of reformed septum within the larger segment, forcing the conclusion that a successful submucous operation, though an insufficient one, had been done previously. The posterior hook-like end of the vomer also continued to cause disturbance. This specimen placed in weak formaldehyd solution and later in alcohol hardened into firm septum, and, on cross-section, as in Figure 5, revealed a well-formed nest of cartilage-cells, some evidence of reforming blood-vessels and a very firm union of the fibrous tissue and the adjacent portions of the cartilage.

Several points of interest arose from this demonstration: First, it was possible a second time to lift the perichondrium, probably a silent testimonial to the skill of the previous worker, and it was possible even to remove this adequately from the junction lines of the repaired and permanent septum. Second, the circulation in and around the septum seems to have been quite adequately restored, and the mucous membrane did not indicate the fact of a previous submucous operation. Third, the body of the repaired tissue was a dense fibrous stroma with occasional interspaces, perhaps circulatory, and containing this nest of growing cartilage-cells. Fourth, the consistency and strength of the septum seemed thoroughly adequate under all manipulative measures prior to the operation.

The question arises as to the reformation of cartilage growth. After careful examination and discussion with various physicians, I have come to believe that the cartilage is probably due to accidental growth and possibly a portion of cartilage left, though showing no bulging. The picture, however, presented both intranasally and subperichondrially and even after removal was that of a perfectly restored septum, somewhat thinner and more pliable than the original. My conclusion is in conformity with evidence repeatedly indicated, that cartilage itself does not reform. The weight of evidence in favor of the reassumption of anatomic and physiologic integrity is, however, most satisfactory.

CONCLUSIONS

1. A submucous resection, properly and completely done, will reconstruct a perfect, functional septum.

2. If a careful superior margin be left, even with scant anterior and posterior sthenic removal, the align-

---

[14] Packard: Diseases of the Nose and Throat.

[15] Roe: Med. Rec., New York, 1905.

ment in the nose externally and internally will be satisfactory and adequate.

3. If the bulging extremities of the nasal tubercles, ridge, and vomer, when obstructing the nares, are not relieved, the result of the operation is unsatisfactory to the patient.

4. The removal of posterior pressure is more important than a harmonious anterior picture, and unequal space in front does not necessarily disturb respiratory and drainage functions.

5. Fresh anastomoses will restore obliterated vessels to the extent of presenting a normal vascular septum if traumatism has not been unreasonable.

6. Areas in which mucous tissues are lost and replaced by squamous epithelium will probably crust, allow occasional intermittent hemorrhage and irritate the nose.

7. Perforations may be avoided if at least one firm side of mucous membrane is allowed to remain intact.

8. In soft, collapsible roof and sides a greater margin of cartilaginous and bony ring should be left to support the flexible nose and prevent drooping.

9. Drainage and perforation posteriorly will not injure the nose and will prevent exudate and hematoma of the septum.

10. Pressure of pads and splints should be avoided by protection of their surfaces and adequate judgment as to amount easily tolerated.

11. Reflex and other symptoms associated with the indication for operation will gradually disappear completely in a large percentage of cases.

12. Submucous removal is the method of preference for all septal procedures, and when carefully and completely performed may afford immeasurable relief.

13. The natural secretion of the nose will prove sufficient for postoperative antisepsis.

14. The new fibrous replaced septum bears approximately the same relation to the perichondrium and periosteum as before.

15. There is no evidence that the softer reorganized septum carries any functional disadvantage, even in its vasomotor relations.

1901 Chestnut Street.

Truth-Telling by Physicians.—Everyone makes mistakes, and on this account if on no other, in the practice of such an inexact science as medicine, a proper humility as to our ability to forecast the future is becoming in members of the profession. The effect of truth—given that it is the truth—on suffering humanity is to be reckoned with in a discussion of the advisability of communicating medical facts to patients. The wise physician realizes that human nature is most diverse in its aspects; he takes into account the greatest number of the traits of character of his patients; he is more often taciturn than talkative; he thinks twice before speaking the truth.—*Boston Med. and Surg. Jour.*

VALUE OF ROENTGENOGRAPHY IN DIAGNOSIS OF DISEASES OF LARYNX AND TRACHEA*

SAMUEL IGLAUER, M.D.
Associate Professor of Otology, Ohio-Miami Medical College, University of Cincinnati
CINCINNATI

The Roentgen rays have proved to be a great aid to the rhinologist and otologist in the diagnosis of diseases of the accessory cavities of the nose, and in the study of the pathology of the mastoid region. In the field of laryngology, on the other hand, the Roentgen rays have been employed chiefly for the study of the development (ossification) and physiology of the larynx. The very complete atlas issued by Thost[1] of Hamburg in 1913 represents the first systematic attempts to study the pathology of the larynx by means of the Roentgen rays.

PHYSIOLOGY

In the domain of physiology the Roentgen rays have demonstrated some interesting facts concerning certain functions of the larynx. Thus the long-debated question as to whether the cricothyroid muscles act as depressors of the thyroid cartilages or as elevators of the cricoid has been definitely settled in favor of the latter by the studies of Moeller and Fischer.[2] The various positions assumed by the lips, tongue, soft palate and larynx during phonation have been accurately determined by the beautiful roentgenograms of Scheier.[3] More remarkable than these are his[4] Roentgen studies of deglutition, in which he was able to portray the position of the bismuth mass in the fractional part of a second required for it to pass the larynx. According to Thost,[1] roentgenography will demonstrate the well-developed muscular apparatus in the larynges of professional singers.

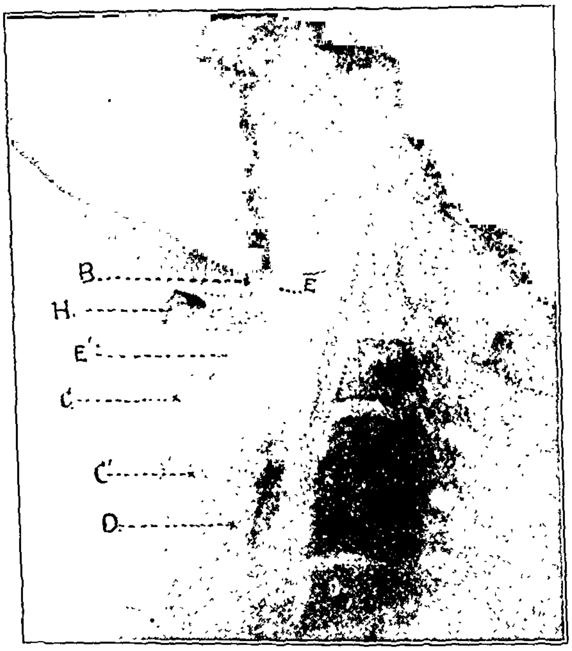

Fig. 1.—Normal larynx of a man, aged 45; *H*, body of hyoid bone. *B*, base of tongue; *E*, *E'*, epiglottis. *C*, *C'*, markedly ossified thyroid cartilage; note the ascending and descending horns of same. *D*, cricoid cartilage. The lumen of the trachea, larynx and pharynx are well delineated.

OSSIFICATION OF THE LARYNX

The Roentgen rays are particularly valuable for the study of the normal process of ossification of the laryngeal cartilages, and in order to appreciate some of the pathologic conditions of the larynx it is important that we should be familiar with the usual course of ossification. According to Scheier[5] and Fraenkel,[6] ossification usually begins during the eighteenth or nineteenth year of life, and in both sexes is first noted in the lower part of the posterior border of the thyroid cartilages. From this region it gradually ascends along the posterior border. Ossification then gradually extends forward along the inferior border of the thyroid, giving rise to an L-shaped mass of bone.

---

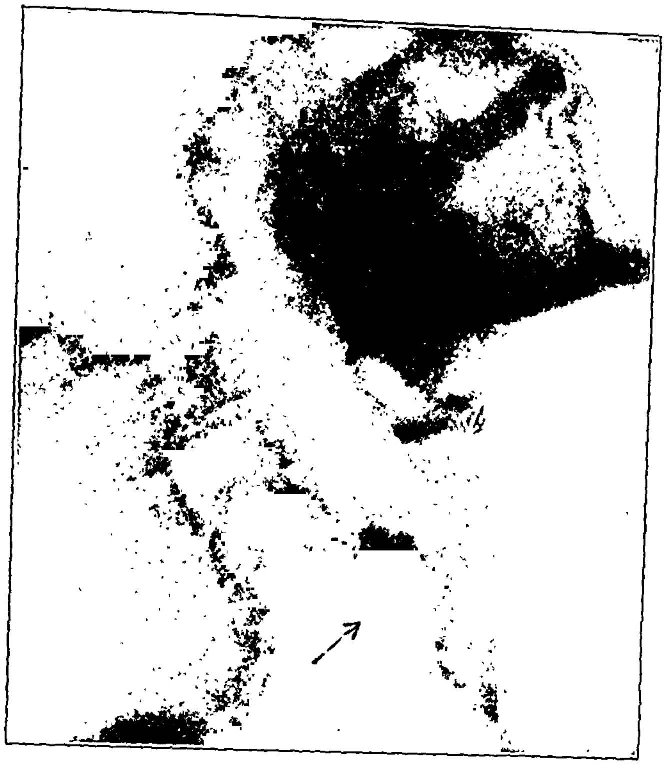

Fig. 2.—Marked ossification of thyroid cartilage in a man aged 50. Note sharp outline of the epiglottis. Upper arrow rests on the body of the hyoid bone.

In the male, a new center arises at the inferior thyroid notch and another along the superior thyroid border, and by the gradual coalescence of all these centers the cartilage eventually may be completely surrounded by a bony frame (after the fortieth year). See Figs. 1 and 2.

In the female the same process may occasionally occur, but more characteristic for this sex is the freedom from ossification in the anterior portions of the thyroid wings.

An oblique bony line dividing the thyroid into two islands is common in the male, but practically always absent in the female.

In the cricoid the process begins in the seal portion and gradually extends forward into the ring portion of the cartilage.

The arytenoids are next in order and the tracheal rings are among the last to show signs of ossification. Roentgenoscopy has proved that ossification may also occur in the epiglottis.

TECHNIC

Roentgenography of the larynx in the living is easily carried out. The patient sits on a chair or lies on a couch with the plate (8 by 10) in contact with the side of the neck and parallel to the median plane of the body. The patient is instructed to hold his breath and not to swallow during the exposure, which requires about six seconds. A profile picture of the larynx is thus obtained with one side of the larynx superimposed on the other, but the side in contact with the plate comes out very distinctly.

All the roentgenograms which form the basis of this paper were taken for me by Dr. Sidney Lange, to whom I am greatly indebted, and who in another paper will more fully describe the technic.

THE NORMAL LARYNX IN THE ROENTGENOGRAM

The roentgenogram reveals the following structures (Fig. 1):

The horse-shoe shaped hyoid (*H*) bone and its two processes stand out sharply, as does the base of the tongue (*B*). The epiglottis (*E*) can be seen projecting between the wings of the hyoid bone. The thyroid cartilage (*C*, *C'*) more or less ossified, is very prominent, while the cricoid (*D*) is covered to some extent by the descending horns of the thyroid. The ventricle of Morgagni is frequently outlined as an oval clearer space in the anterior portion of the thyroid. The arytenoids and aryepiglottic folds and the cricothyroid space can be distinguished. The lumen of the larynx appears distinctly as a lighter area continuous below with the well-defined lumen of the trachea in which the rings, when ossified, stand out distinctly. Before ossification occurs the cartilages are not well delineated, but the air-passages themselves stand out sharply and distinctly in the roentgenogram. (See Fig. 5).

TUBERCULOSIS OF THE LARYNX

Quite characteristic for the roentgenogram of this disease is a peculiar hazy indistinct outline of the laryngeal cartilages, giving the impression of an over-exposed picture. This type of picture recurs so frequently with the tuberculous larynx that it has great value from a diagnostic point of view. It indicates very clearly that the tuberculous process is not confined to the lining mucosa of the larynx, but that

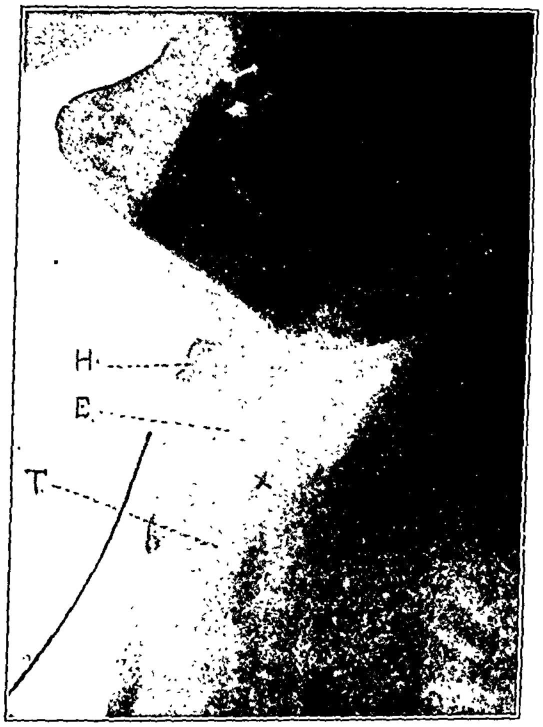

Fig. 3.—Tuberculosis of larynx in a man aged 33, with advanced pulmonary tuberculosis. Subcutaneous tuberculous (?) fistula, containing probe in front of thyroid cartilage. Infiltration of aryepiglottis folds demonstrated at *X*. Hazy appearance of *T*, thyroid cartilage, that is, resorption of lime-salts characteristic for laryngeal tuberculosis. Note dense center of ossification in anterior unaffected portion. *H*, *hyoid bone, and E, epiglottis well delineated. Note lumen of larynx* and trachea.

[5] Scheier, M.: Ueber die Ossifikation des Kehlkopfes, Arch. f. mikr. Anat. u. Entwicklungsgeschichte, *1901*, *lix*; Schäfer-Passow Beitr., 1910, iii, No. 4.

[6] Fraenkel, E.: Fortschr. a. d. Geb. d. Roentgenstrahlen, 1908, xii, 152.

changes occur in the underlying cartilage associated with the resorption of bone. This is distinctly analogous to rarefying changes so frequently noted in roentgenograms of the long bones when the joints are the seat of tuberculous disease. In addition to the changes in the cartilage the infiltration of the soft parts, such as the aryfolds, stand out distinctly. Defects or infiltration of the epiglottis give characteristic pictures.

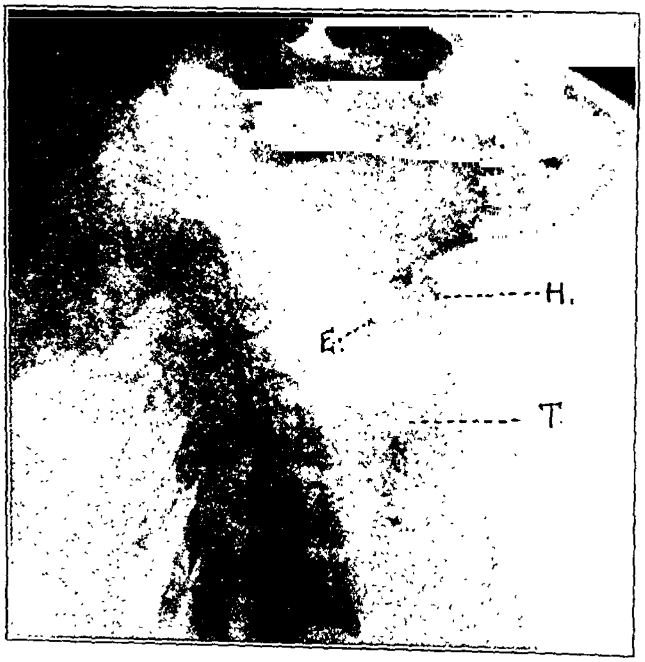

Fig. 4.—Case of carcinoma of hypopharynx in a woman aged 40. The peculiar punched-out appearance of the thyroid cartilage, *T*, is regarded by Thost as characteristic (?) for carcinomatous invasion of the thyroid cartilage from the pharynx (see text). *H*, the hyoid bone, *E*, epiglottis and the laryngotracheal lumen clearly delineated.

Roentgenography offers another demonstration of the fact that tuberculous lesions are almost always more extensive than the image in the laryngeal mirror would indicate. (Fig. 3).

SYPHILIS

In contrast to tuberculosis, tertiary syphilis of the larynx is usually associated with a tendency to proliferation rather than to resorption of bone. The roentgenograms in syphilis, therefore, give sharp distinct pictures of the ossified portions of the larynx (Thost). Infiltration or defects in the soft parts may also be made out. In the roentgenogram of a healed case coming under my observation a peculiar cavity, probably due to a former necrosis, is seen above the thyroid cartilage. In another healed case of laryngeal and pharyngeal syphilis associated with the formation of dense cicatrices in the pharynx, the distortion of the lumen of the larynx by cicatricial traction is very well demonstrated.

In doubtful cases, roentgenography should be of considerable value in demonstrating syphilitic perichondritis and in differentiating syphilis from tuberculosis.

CARCINOMA

Carcinoma of the larynx usually occurs in the ossified larynx of the aged, and this tends to obscure intralaryngeal tumors. Nevertheless, a massive tumor can often be made out, and if the lumen be encroached on, the narrowed air-passage can be seen. Tumors of the epiglottis or aryfolds are more readily delineated. In carcinoma of the hypopharynx, with secondary involvement of the larynx, Thost describes roentgenograms with a sieve-like appearance of the thyroid cartilage which he attributes to carcinomatous invasion of the ossified cartilage. Since the same picture may occur in normal larynges, however, and since I have not found it in any of the four intralaryngeal cancers which have been roentgenographed, and but once in three cases of carcinoma of the pharynx, it seems to me that he has overestimated the importance of these findings. (Fig. 4).

STENOSES OF THE LARYNX

In obstruction of the larynx or trachea by foreign bodies, or by tumors or cicatrices within the air-tract, or by compression from without, very interesting roentgenograms can often be obtained. The tumor is often visible and the narrowed lumen appears distinctly.

In one of my cases of papilloma, which required tracheotomy, the roentgenogram shows the entire lumen obliterated above the tracheotomy tube. In a second case of stenosis due to cicatrization following intubation and tracheotomy for diphtheria, the roentgenogram, taken for control, showed a complete restoration of the lumen after treatment.

Roentgenography demonstrates very beautifully the deposits of lime-salts which so frequently occur when the laryngeal or tracheal cartilages have been incised. Thus in a patient who has worn a tracheal cannula for seven years the fistula from the skin to the trachea is completely encased in calcified tissue (Fig. 6).

Considering the difficulties often encountered in examining cases of stenosis by the direct method, a preliminary roentgenogram should often prove to be a great aid to the laryngologist. This is especially true of foreign-body cases, or in cases of aneurysm, goiter or enlarged thymus. (Fig. 5).

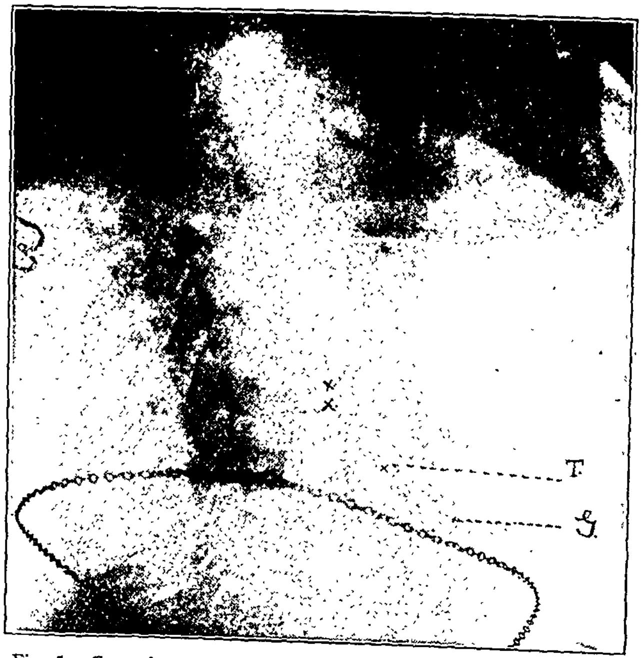

Fig. 5.—*G*, moderate-sized goiter, showing its relation to the trachea, *T*, in a girl aged 19. At *X*, *X*, slight ossification in posterior portion of thyroid cartilage. Air-passages delineated by clear zone.

RARE DISEASES AND FRACTURES OF THE LARYNX

In addition to the diseases described above, Thost has made interesting Roentgen studies of the gouty larynx and of pemphigus of the larynx. In certain so-called nervous lesions of the throat, he has demonstrated on the bodies of some of the cervical vertebrae new-formed spines and ridges to which he attributes the "nervous" symptoms.

In a limited number of cases, I have fractured the larynges in cadavers and have then had roentgenograms taken. In each instance fracture-lines can be demonstrated (Fig. 7). I hope to be able to report more fully on this particular subject at some future time.

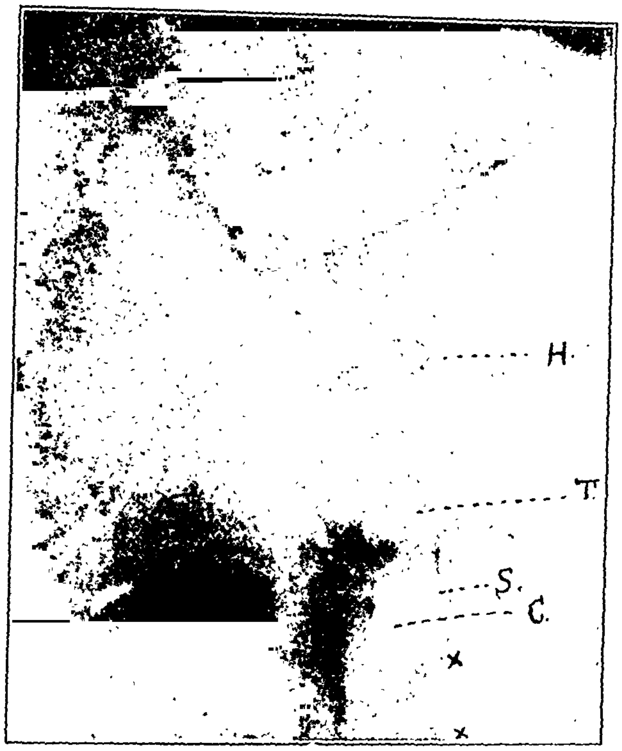

Fig. 6.—Calcified tissue at *X*, *X*, encasing a tracheotomy fistula in a patient who has worn a tracheotomy tube for seven years. *C*, the cricoid cartilage. *S*, cricothyroid space. *T*, the ossified thyroid with its inferior and superior horns. *H*, the hyoid bone, and the epiglottis, are well delineated.

CONCLUSIONS

Satisfactory diagnoses of diseases of the larynx and trachea can usually be made by the ordinary method of examination, but our observations for the most part are limited to a study of the changes in the lining mucous membrane and give no certain information concerning the changes in its underlying and adjacent structures.

The Roentgen examination gives additional information concerning the pathologic changes in the underlying cartilages, which are more or less involved whenever the laryngeal mucous membrane is the seat of a chronic disease process, such as tuberculosis or syphilis.

In stenosis or distortion of the lumen of the larynx or the trachea, roentgenography usually reveals the seat, the nature and the extent of the lesion. The knowledge thus gained before operative procedures are undertaken on the larynx is of great value. Roentgenography also enables us to study the effects of operation and the position of tubes, etc.

Owing to the ease with which it is carried out, the Roentgen method is of a special value in the examination of children or nervous patients.

In concluding I wish to express my appreciation of the kindness of Drs. A. B. Thrasher, S. E. Allen and William Mithoefer in placing some of their patients at my disposal for Roentgen study.

22 West Seventh Street.

ABSTRACT OF DISCUSSION

Dr. G. E. Pfahler, Philadelphia: The more or less new work done by Dr. Iglauer in the diagnosis of disease in the larynx opens up a new field in which I am sure we will make progress. We have all seen these things, but most of us have failed to interpret them properly, but with this aid we will certainly make rapid advances in this respect. I have not made much attempt to diagnose diseases of the larynx. In my studies of the larynx and neck I have seen some of these changes but did not interpret them properly. Dr. Skillern and I presented a paper on sphenoidal disease three years ago and the more I use the method and the more I study these sinuses, the more I am convinced of the value of this work. The two sphenoid outlines can be compared directly and if looked at as a whole one stands out more clearly than the other and the definite outline of the sphenoid can be noted in nearly every one of the plates. We should be just as careful in interpreting the sphenoid sinuses as the others.

Dr. P. M. Hickey, Detroit: The work that has been shown this morning in the differentiation of soft tissue details would be accentuated by the recent improvements which are coming out in the ability of the roentgenologist to control the performance of his tubes. We have been missing the soft tissue details because we have not been able to control accurately the performance of the tube. We have used the three gradations, hard, medium and soft, with no exact means of differentiation. The late improvements which some of the roentgenologists have placed at our disposal, in getting exact regulation of the tubes for soft tissue details, will enable us to make greater progress along this line. One thing about the trachea is the importance of the outline in the anteroposterior position, with the plate against the chest, of substernal thyroid, where perhaps there is no visible tumor on the outside, and yet where compression of the trachea can be beautifully demonstrated on the plate.

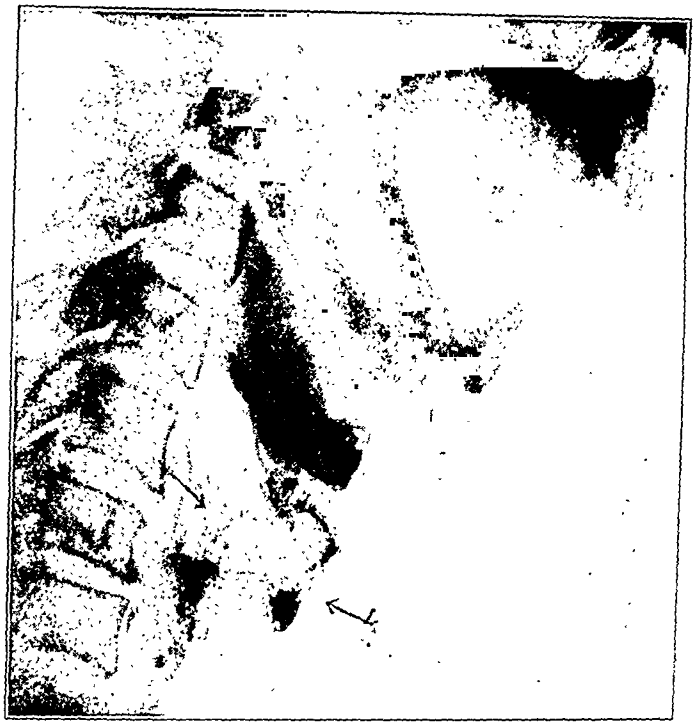

Fig. 7.—Fractured larynx in cadaver of a man aged 69.

Dr. E. W. Caldwell, New York: Will Dr. Iglauer explain again the difference between the calcification of the larynx alleged to be characteristic of syphilis, and that which is alleged to be characteristic of carcinoma? Also does he think that calcification or ossification in the larynx is essentially different from the same process in other cartilages, such as the costal cartilages? Has he observed that the degree of calcification of the larynx bears any relation to the amount of calcification of other cartilages in the same individual?

Dr. Mark D. Stevenson, Akron, Ohio: I recently had a case of marked stenosis of the larynx which necessitated immediate tracheotomy. The roentgenograms showed conclusively that it was a case of acromegaly. The pictures demonstrated ossification of the larynx and the condition of the pituitary body.

Dr. G. C. Johnston, Pittsburgh: I had the pleasure of examining the patient just referred to by Dr. Stevenson, a case of acromegaly, and the examination of the larynx was interesting. I had not previously associated these cases of acromegaly with involvement of the larynx at all. The patient had the typical gingerbread-man hands and characteristic features. Not long ago in investigating some pituitaries, we found one that was ideal for the Cushing operation, having all the indications. The surgeon went in to perform submucous resection and just when he was completing that and was about to enter the sphenoid there was a gush of pus which was a contra-indication for going further. The lesson is not to look too much in one place. We failed to see the evidence of necrosis in the hard palate. We must be looking for trouble all the time or we will find it without looking for it.

Dr. A. I. Weil, New Orleans: I have had little experience with roentgenograms of the larynx except one case in which its use was shown, that of a man who had had ossification of the arytenoids which had sloughed out, so that he coughed up one complete arytenoid, and later the other. He brought the specimens to me and when we looked into the larynx there was sinking of the arytenoid region, but we could not have told to what it was owing if we had not seen these specimens. With the roentgenogram, although the picture was hazy, it was easy to see the absence of the arytenoids. Without that it would have been impossible to state the condition that had preceded his presenting himself for treatment. I have used the Roentgen ray in bone lesions in retropharyngeal abscess on several occasions, and find it a very valuable aid to examination witn the probe. It outlines very clearly the cavity and aids in the treatment.

Dr. Harris P. Mosher, Boston: This paper teaches that we should take more radiograms of the larynx and endeavor to learn to interpret them properly. I had a rather embarrassing and somewhat humorous case of a retired manufacturer who had taken up farming. He was building a chicken coop and had a lot of staples in his mouth, and thought that he had swallowed one. Sometime later he had some disturbance and went to a general physician who took a roentgenogram and told him the staple was there, and brought the patient down for me to see. On looking at the roentgenogram I was a bit suspicious; I examined the man by the direct method, and was still more suspicious. I sent him for another picture and found that what had shown in the first picture was nothing more nor less than the hyoid bone.

Dr. George F. Cott, Buffalo: All laryngologists acknowledge the value of roentgenograms but the average cases that the practitioner sees are not the ones shown. When there is considerable thickening in the larynx it shows, but when there is a rarefying condition the Roentgen ray shows nothing, and they are the cases that the average practitioner sees.

Dr. L. E. LeWald, New York: I had two cases of retropharyngeal abscess that we were able to differentiate successfully in children. A physician who saw one of the cases was of the opinion that it was tuberculosis of the cervical vertebrae, with probably abscess of that origin, which would preclude opening the abscess in the pharynx. Roentgenoscopy disclosed not only absence of any bone lesion in the vertebrae but also, very distinctly, the outlines of an abscess in the pharynx, and it was opened successfully. Another patient in whom there was swelling in the pharynx, associated with tuberculosis of the cervical lymph-nodes, showed an outline in the pharynx sufficiently well to warrant incision. One other case of interest was that of a supposed tumor, as carcinoma of the upper end of the esophagus, in which the Roentgen ray enabled us to exclude a tumor and make a diagnosis, when taken together with other symptoms, of glossolabiolaryngeal paralysis.

Dr. Samuel Iglauer, Cincinnati: Dr. Hickey referred to pictures of the trachea. I did not go into that subject much because it has been worked out pretty well by the roentgenologist. I have a picture, however, which shows a kink in the trachea due to pleuritic adhesions pulling it out of line. In compression of the trachea by a thyroid tumor, it is, of course, necessary to have anteroposterior pictures. Dr. Caldwell asks about calcification and ossification in the larynx. It is difficult to reduce the matter to rules, but I think according to the work of Fraenkel and Scheier, that it begins at about the age of 19. Sometimes you find it at 14 or 15 years, but you may find a woman as old as 100 without any distinct ossification in the anterior portions of the thyroid cartilage. Calcification usually precedes ossification. I mentioned the relation of the vertebrae to laryngeal conditions. With an abscess in the retropharynx, it is very important to study the condition of the vertebrae. I have had no experience with acromegaly and am interested in the report made by Dr. Stevenson and Dr. Johnston. With regard to Dr. Weil's case, some studies have been made on the question of dislocation of the arytenoid cartilages, and it has been possible to diagnose the condition by the Roentgen ray. As to Dr. Mosher's case, it is easy to understand how that mistake could be made, as the hyoid bone would have the appearance and shape of a staple. Just the reverse of his experience occurred to me. A patient was brought to me with the statement that roentgenogram had shown no foreign body, but I had another taken which revealed a safety pin which had been in the larynx for six months.

THE FEEDING VALUE OF SANATOGEN COMPARED WITH COMMERCIAL CASEIN WITH RESPECT TO MAINTENANCE AND GROWTH

JOHN PHILLIPS STREET, M.S.
Chemist Connecticut Agricultural Experiment Station
NEW HAVEN, CONN.

The proprietary preparation "Sanatogen" is claimed to consist of about 95 per cent. casein and 5 per cent. sodium glycerophosphate. The analysis of C. B. Morison[1] is as follows:

Water	9.97
Total nitrogen	12.81
Nitrogen, ppt. by acetic acid	12.54
Casein	80.01
Ether extract	0.11
Ash	5.59
Sulphur, total	0.73
Sulphur in casein	0.64
Phosphorus, total	1.49
Phosphorus in casein	0.69
Phosphorus in inorganic form	0.11

In connection with the above analysis it was demonstrated that sodium glycerophosphate was present. Sanatogen, therefore, consists essentially, on the water-free basis, of about 90 per cent. casein and 5 per cent. sodium glycerophosphate, with a small amount of an unidentified nitrogenous compound containing both sulphur and phosphorus, and a small amount of phosphorus in inorganic combination. The manufacturers claim that the two essential ingredients exist in Sanatogen as a definite chemical compound. Certain authorities, on the other hand, have insisted that the casein and glycerophosphate have not been chemically combined and that Sanatogen is simply a mechanical mixture of the two. Which claim is correct we will not consider here, for indeed it is of little importance, for whether or not chemically combined the action of the digestive fluids of the body would speedily break down the alleged compound into its constituents, and the body would have casein and the glycerophosphate offered for its use, just the same as though they had been offered as a mere mechanical mixture.

---

[1] Morison, C. B.: Rept. Conn. Agric. Exper. Station, 1912, p. 197.

It being apparent that Sanatogen consists almost entirely of casein and sodium glycerophosphate, the former well-known ingredient making up nine-tenths of its weight, the question naturally arises how a mixture of these two common substances can acquire, simply by that admixture, unusually valuable properties not possessed by the two components. Leading physiologists quite generally agree that phosphorus in the form of glycerophosphates influences metabolism very little. Furthermore, it is obvious that the food value of the small amount of glycerin present must be slight. It is apparent, therefore, that whatever nutriment or energy Sanatogen supplies must be dependent on its main constituent, casein.

Sanatogen is commonly sold at retail in 100 gm. or 200 gm. packages for $1 and $1.90, respectively. It is possible that in larger quantities these prices might be shaded somewhat, but the fact remains that the ordinary retail purchaser of Sanatogen pays for it about 1 cent per gram, or about $4.50 per pound. If the value of Sanatogen depends on its casein, one might ask, in all fairness, why should the patient pay $4.50 per pound for Sanatogen when he can secure ordinary commercial casein for 8.5 to 10 cents per pound? (The Casein Mfg. Co. of New York quoted to me their No. 60 casein at 10 cents per pound in 5-pound lots, 8.5 cents per pound f. o. b. Bainbridge, N. Y., in 100-pound lots, and 8.5 cents per pound, freight paid, in 500-pound lots.) I have purchased Sanatogen from a wholesale druggist at the rate of $2.75 for 400 gm., or $3.12 per pound, so that under the most favorable conditions the cost of Sanatogen is more than thirty times as great as the commercial casein in question.

Is the consumer justified in paying this exceedingly high price for purified casein? The following feeding experiments were carried out to answer this query.

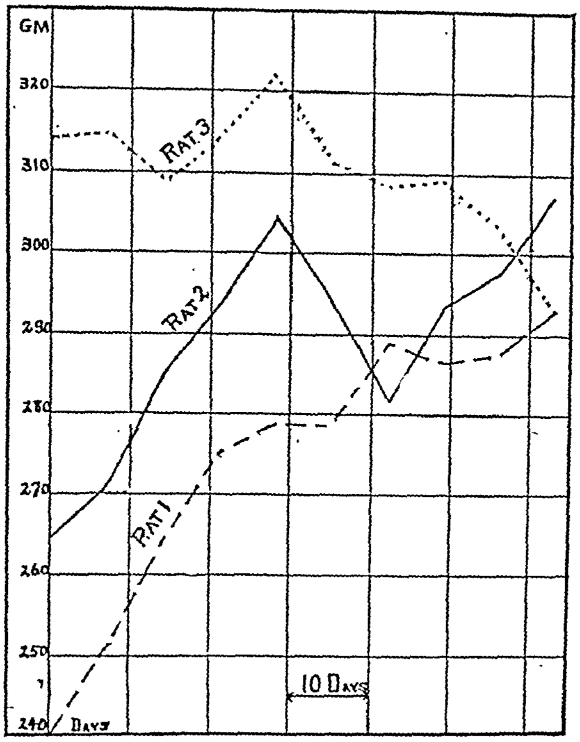

Chart 1.—Growth curves of Rats 1, 2 and 3, on Ration 1: Casein.

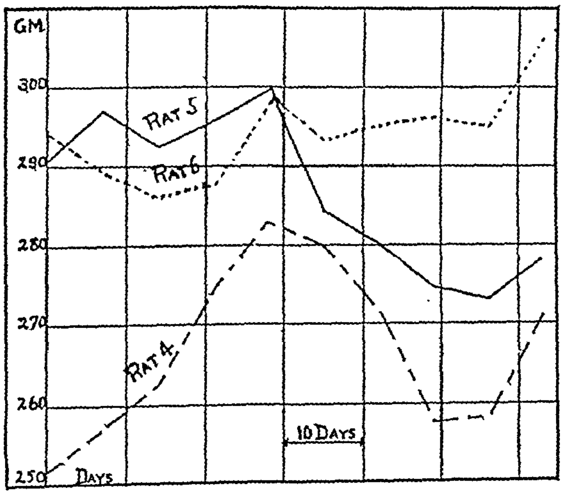

Chart 2.—Growth curves of Rats 4, 5 and 6, on Ration 2: Sanatogen.

FEEDING EXPERIMENTS

White rats were chosen for the experimental animals because of their adaptability for tests of this kind, as shown by the extended successful experience of Osborne and Mendel, and also because, by using white rats, I could take advantage of the equipment and the experience of my colleagues, Dr. T. B. Osborne, Prof. L. B. Mendel and Miss Edna L. Ferry.

The value of Sanatogen as compared with commercial casein was studied from two points of view:

1. Its value in maintaining the weight of mature rats.
2. Its value in promoting the growth of young rats.

I. THE MAINTENANCE OF WEIGHT OF MATURE RATS

The Sanatogen used contained 12.88 per cent. of nitrogen, and the casein, 12.82 per cent., so that from the point of view of nitrogen content they were practically equivalent, gram for gram.

Six healthy male animals were

* The growth curves of Rats 1, 2 and 3 are given in Chart 1.

selected, Rats 1, 2 and 3 being fed the casein ration and Rats 4, 5 and 6 the Sanatogen ration. At the beginning of the experiment the casein rats were 257, 360 and 376 days old; the Sanatogen rats, 249, 321 and 275 days old, respectively. These weight conditions, if anything, slightly favored the Sanatogen rats, as they were slightly less mature, and a greater growth might naturally be expected.

The rations fed had the following percentage composition:

Ration 1		Ration 2	
Casein	20	Sanatogen	20
Protein-free milk*	28	Protein-free milk*	28
Lard	8	Lard	14
Unsalted butter	18	Unsalted butter	18
Corn starch	26	Corn starch	20

* Osborne and Mendel: Feeding Experiments with Isolated Food Substances, Carnegie Inst. of Washington, Publ. 156, 1911, Part 2, p. 80.

The rats were weighed twice a week for nine weeks, a record of the food consumed also being kept. Table 1 shows the weekly weights of the casein rats, the weekly gain or loss, and the weekly consumption of food. Table 2 gives similar data for the Sanatogen rats.

TABLE 2.—WEIGHTS OF SANATOGEN RATS, RATION NO. 2, OVER A PERIOD OF NINE WEEKS*

	Weight, gm.	Gain or Loss, gm.	Food Eaten, gm.	Weight, gm.	Gain or Loss, gm.	Food Eaten,	Weight, gm.	Gain or Loss, gm.	Food Eaten, gm.
1/2	251.8	.....	.....	290.6	......	....	294.0	......	.....
1/9	257.1	+ 5.3	73.4	297.2	+ 6.6	86.3	289.1	— 4.9	58.4
1/16	262.4	+ 5.3	89.8	292.4	— 4.8	88.9	286.1	— 3.0	76.8
1/23	274.4	+12.0	97.3	295.7	+ 3.3	92.8	287.6	+ 1.5	85.8
1/30	282.7	+ 8.3	95.5	299.5	+ 3 8	92.3	298.6	+11.0	90.9
2/6	279.8	— 2.9	97.7	284.2	—15.3	87.7	292.9	— 5.7	89.8
2/13	271.2	— 8.6	96.1	280.0	— 4.2	94.9	295.1	+ 2.2	99.7
2/20	257.5	—13.7	91.6	274.9	— 5.1	96.4	296.0	+ 0.9	93.9
2/27	258.0	+ 0.5	93.5	273.0	— 1.9	103.3	295.0	— 1.0	95.1
3/6	270.9	+12.9	94.8	278.1	+ 5.1	94.9	306.3	+11.3	89.4
Total	.....	+19.1	829.7	.....	—12.5	837.5	.....	+12.3	779.8
Average per week	.....	+2.7	92.2	.....	— 1.4	93.1	.....	+ 1.4	86.6

* The growth curves of Rats 4, 5 and 6 are given in Chart 2.

Certainly the above data show no superiority of Sanatogen over commercial casein. In fact the results might be taken to suggest a slight advantage for the cheaper article, if one were warranted in drawing fine distinctions from a limited number of animals.

To conclude, *a comparative feeding of six male white rats during nine weeks showed no nutritive superiority of Sanatogen, costing $3.12 per pound, over commercial casein costing 10 cents per pound.*

II. THE PROMOTION OF GROWTH IN YOUNG RATS

In the second series of experiments ten male rats were used with four different rations. In these, casein and Sanatogen were compared, using both Osborne and Mendel's "protein-free milk" and their "artificial protein-free milk IV."[2] Butter fat was also substituted for the unsalted butter used in Rations 1 and 2.

The percentage composition of the rations fed was as follows:

Ration 3		Ration 5	
Casein	20	Casein	20
Protein-free milk	28	Artificial p.-f. milk IV	29
Lard	8	Lard	8
Butter-fat	18	Butter-fat	18
Corn starch	26	Corn starch	25
Ration 4		**Ration 6**	
Sanatogen	20	Sanatogen	20
Protein-free milk	28	Artificial p.-f. milk IV	29
Lard	14	Lard	14
Butter-fat	18	Butter-fat	18
Corn starch	20	Corn starch	19

Two male rats were used with each of Rations 3 and 4, and three with each of Rations 5 and 6. They were all healthy young rats ranging from 57 to 71 days old. As in the first series of experiments the rats were weighed twice a week and a record kept of the food consumed. Rations 3 and 4 were fed for 77 days, Rations 5 and 6 for 35 days.

Table 3 shows the weekly weights and gains or losses of the rats fed Rations 3 and 4.

Rat 8 suffered more or less from diarrhea during a considerable part of the experiment, covering a period from March 16 to April 9, and from April 13 to May 11. The food intake correspondingly decreased during those periods.

The difference in the gains in weight shown by the four rats are not great and certainly do not warrant the conclusion that Sanatogen possesses any marked superiority over the commercial casein in promoting growth. The slightly increased gains shown by Rats

4/13	198.5	+10.7	157.6	+ 8.8	185.6	+ 12.5	166.1	+ 22.3
4/20	204.6	+ 6.1	164.6	+ 7.0	194.8	+ 9.2	179.4	+ 13.3
4/27	210.3	+ 5.7	167.2	+ 2.6	204.6	+ 9.8	191.0	+ 11.6
5/4	223.0	+12.7	179.6	+12.4	222.9	+ 18.3	204.7	+ 13.7
5/11	223.6	+ 0.6	191.6	+12.0	236.4	+ 13.5	210.8	+ 6.1
5/18	231.5	+ 7.9	203.6	+12.0	240.0	+ 3.6	218.6	+ 7.8
5/25	237.4	+ 5.9	213.9	+10.3	247.3	+ 7.3	226.7	+ 8.1
Total	.....	+95.2	.....	+105.9	.....	+119.5	.....	+119.7

9 and 10 are entirely incommensurate with the cost of the Sanatogen. All of the rats showed a vigorous growth and exceeded the average weight expected for rats of their respective ages, based on the long series of observations of Osborne and Mendel, as shown in Table 4.

TABLE 4.—WEIGHT OF RATS 7 TO 10 COMPARED WITH AVERAGE WEIGHT OF RAT OF SAME AGE

Rat	Age in Days	Final Weight, gm.	Average Weight for Rat of Same Age, gm.
7	148	237	204
8	138	214	201
9	145	247	204
10	134	227	197

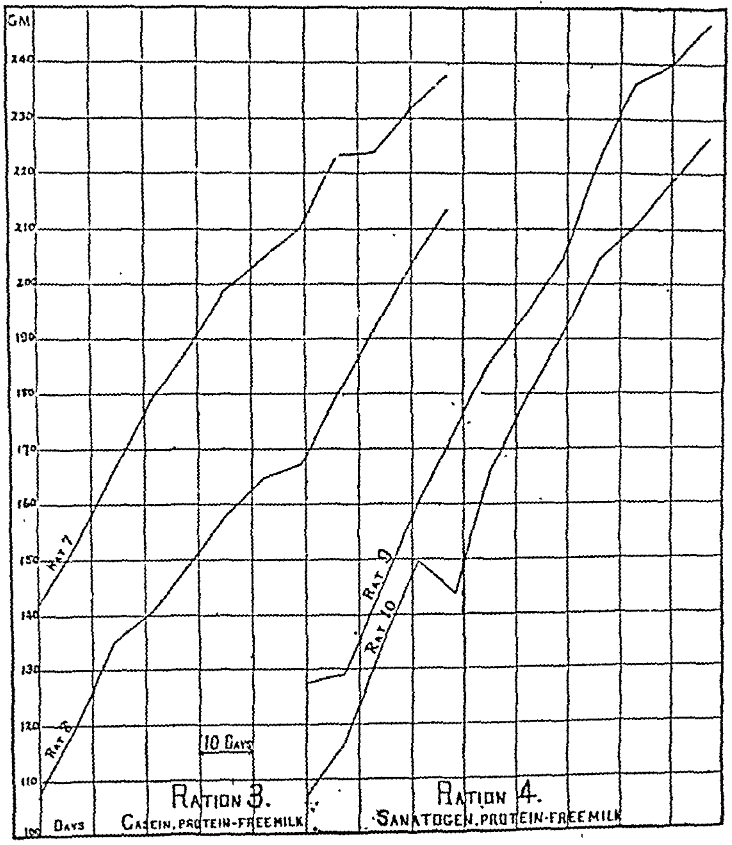

Chart 3.—Growth curves of Rats 7, 8, 9 and 10 on Rations 3, Casein, protein-free milk, and 4, Sanatogen, protein-free milk.

Rat 13 suffered more or less from diarrhea throughout the whole experiment, and Rat 16 suffered similarly during the first two weeks.

The results secured by Rations 5 and 6 compared with Rations 3 and 4, the only difference being that natural protein-free milk was used in the latter and artificial protein-free milk in the former, are most striking. Such results were anticipated from the experience of Osborne and Mendel in feeding similar materials. All of my rats, except Rat 13, a casein rat, showed a decided loss in weight after five weeks' feeding on rations containing artificial protein-free milk. These losses amounted to 19.7, 9.0, 23.1, 6.7 and 27.6 gm., whereas rats fed on the same rations, except for the form of protein-free milk, gained, during the same period of five weeks, 56.3, 49.6, 57.8 and 59.1 gm. The fact that one casein rat fed on the artificial protein-free milk showed a substantial gain is without significance, as such exceptions to the general rule occur occasionally, and, furthermore, this rat also during the last week of the experiment likewise lost weight. The extent of these losses compared with what the average normal male rat weighs at a corresponding age is shown in Table 7.

TABLE 5.—WEIGHTS OF RATS FED RATION 5, CASEIN, ARTIFICIAL PROTEIN-FREE MILK*

* Date 4/20 covers use of mixed food.

That these losses in weight were not due to any inherent weakness in the rats is shown by the fact that by feeding Rats 11 to 16 for one week after the termination of the experiment with Osborne and Mendel's

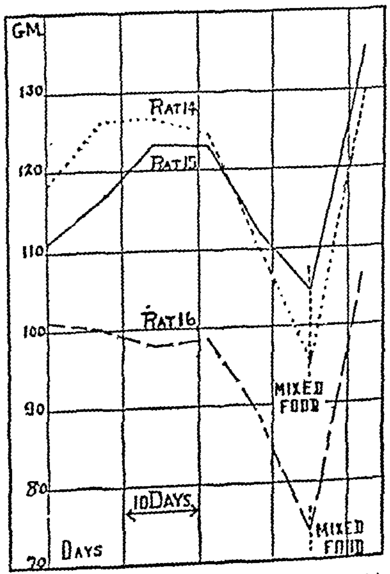

Chart 5.—Growth curves of Rats 14, 15 and 16, on Ration 6: Sanatogen, artificial protein-free milk.

"mixed food" (a mixture of dog bread, sunflower seeds, vegetables and meat) very large gains were secured in every instance, ranging from 14 to 35 gm.

The growth curves for Rats 7 to 16 are shown in Charts 3, 4 and 5.

TABLE 7.—WEIGHT OF RATS 11 TO 16 COMPARED WITH AVERAGE WEIGHT OF RAT OF SAME AGE

Rat	Age, Days	Final Weight, gm.	Average Weight of Rat of Same Age, gm.
11	106	112	167
12	106	144	167
13	99	90	162
14	106	95	167
15	92	105	153
16	96	74	158

To conclude, *a comparative feeding of four male white rats during eleven weeks, showed, if anything, a slightly greater, but insignificant, increase in weight for Sanatogen over commercial casein. In a ration in which artificial had been substituted for natural protein-free milk, Sanatogen showed no advantage over commercial casein in checking the failure in weight of the rats.*

BACTERIOLOGY OF CHOLECYSTITIS AND ITS PRODUCTION BY INJECTION OF STREPTOCOCCI *

E. C. ROSENOW, M.D.
CHICAGO

The bacteriology of cholecystitis, as worked out heretofore, is largely the bacteriology of the contents and not the tissue of the gall-bladder wall. (The mechanism of infection of the gall-bladder and the production of gall-stones have not been fully worked out experimentally.) In a previous paper I pointed out that when streptococci, from various sources, attain a certain grade of virulence, they are prone to produce on intravenous injection cholecystitis and gall-stones, with large numbers of streptococci as the nuclei. In this connection the observations in the following case are of interest:

A woman, aged 62, with infected tonsils, high blood-pressure, and a chronic arthritis, involving chiefly the small joints of the hands, contracted a "cold" and acute tonsillitis. Ten days later she developed a typical acute attack of cholecystitis. The symptoms continued for three weeks without jaundice. Then the pain shifted and the next day jaundice appeared, which deepened for a week and then gradually subsided. Jan. 19, 1914, five weeks after the beginning of the attack, an operation was made by Dr. Bevan. There was found a healing area, 1 by 1.5 cm., of necrosis at the fundus; but otherwise the gall-bladder was nearly normal.

The bladder was moderately distended with bile containing mucus and three soft "mulberry" cholesterin stones. Cultures from the bile were sterile; streptococci, colon bacilli and gas bacilli developed from the center of two of the stones, while from the emulsion of the excised piece of tissue only streptococci developed. The streptococci from both of these sources produced grayish-green, moist, non-hemolyzing colonies on blood-agar and marked precipitation and acidity on dextrose-agar. They formed chains of diplococci and a large number of round cocci, which were often in masses, like some of the strains obtained from gastric ulcer. Sections from the wall of the gall-bladder, stained by Gram's method, showed a moderate number of streptococci.

Dog 57, of medium size, was injected intravenously, January 22, with the growth of the streptococcus from the wall of the gall-bladder in 90 c.c. of ascites-dextrose broth, suspended in 7 c.c. of sodium chlorid solution.

January 24: Lame in the left hind leg. Fluid from knee-joint turbid. Cultures were made.

January 26: Cultures from knee-joints showed four, green-producing, non-hemolyzing streptococci.

January 30: Found dead. Acute cholecystitis, enteritis, localized pancreatitis and nephritis. The wall of the gall-bladder was edematous, from 3 to 6 mm. thick; the mucous membrane was velvety, and covered in areas with a loosely adherent exudate; the cavity was distended with brownish fluid, containing masses of pus and mucus; pressure on the gall-bladder failed to discharge bile until the plug of the mucopus in the diverticulum was removed by passing a probe and by making firm pressure; a moderate number of dark concretions, of the consistency of putty, were found in the masses of mucopus in the gall-bladder and in the plug in the diverticulum. Smears from the crushed concretions, washed repeatedly in sodium chlorid solution, showed many streptococci. The liver was normal; there were whitish streaks in the medullary portion of the kidney, most numerous and largest near the pelvis, where a number of small ulcers were found; the cortex appeared normal; the urine contained leukocytes, some albumin and bile, and was highly acid; the mucous membrane of the lower end of the small intestine was hyperemic and covered with exudate in which were many streptococci; the fluid in the knee-joints was slightly turbid; the stomach, large intestine, adrenals, thyroid, lungs and heart were normal.

The bile, the plug of mucus and the wall of the gall-bladder yielded large numbers of streptococci. The joint fluids and the pelvis of the kidney gave a few colonies of non-hemolyzing streptococci. The blood remained sterile. Sections of the wall of the gall-bladder showed marked thickening and degeneration of the mucous membrane. Gram-Weigert stains show a large number of streptococci, especially in the submucosa.

The fluid contents of the gall-bladder, the center of stones, and particularly parts of the wall of the gall-bladder of twenty-nine cases of cholecystitis have now been studied according to my new method.[1]

I wish here to express my very great appreciation for the opportunity afforded me recently at the Mayo Clinic where most of the cases occurred.

In five cases, the cultures from the wall were negative and in these the microscopic evidence of any changes was slight. In the remaining twenty-four cases, in all of which increase in thickness and other changes were more marked, streptococci were isolated in all but three and in pure culture in ten. In sixteen cases streptococci were found in the wall when the contents were sterile or contained only the colon bacillus. The colon bacillus was found with the streptococcus in only ten cases, once in pure form, once in association with the *Bacillus welchii,* and once with the staphylococcus. *Bacillus mucosus* was found in two cases of very acute cholecystitis. In two, diphtheroid bacilli were found and in one the fusiform bacillus was found. The fluid contents, usually bile, were examined in twenty-six cases: In twelve it was sterile; streptococci were found six times, colon bacilli nine times; staphylococcus three times; the *Bacillus mucosus* twice, and the fusiform bacillus once. The center of gall-stones have been examined in thirty cases. Only two proved sterile; from the rest, streptococci were isolated in all but three, fourteen times in pure form and five times in association with the colon bacillus; the center of the stone, in one case, showed the typhoid bacillus in pure form while the center of two stones and the wall of the gall-bladder in a case with a clinical diagnosis of typhoid cholecystitis showed streptococcus in pure culture; in two cases the center of stones contained colon bacillus and the *Bacillus welchii*, and one the latter organism only; in some instances, streptococci were demonstrable in smear preparations from the center. Cultures from other portions of stones were usually sterile. The adjacent lymph-glands were examined in five cases. Streptococci were found in four, pure in three cases and in association with the *Bacillus welchii* in one case. In the cases in which a pure culture of the streptococcus was obtained from the tissue of the gall-bladder there seemed to be a definite relation between the number of colonies which developed and the degree of change, especially if relatively recent inflammation was present.

---

[1] Rosenow, E. C.: The Newer Bacteriology of Various Infections as Determined by Special Methods, The Journal A. M. A., Sept. 12, 1914, p. 903.

A comparison of the results obtained from the bile, the stones and the wall of the bladder, in the individual cases, shows that a bacteriologic examination of the fluid contents gives trustworthy results only in the acute stage of the disease; during convalescence and in chronic cholecystitis the results are of little value and may be misleading. In chronic cholecystitis the bacteriology of the center of the stones is similar to that of the wall of the bladder.

The effect of the various organisms on intravenous injection has been tested in dogs and rabbits. All of the five strains of streptococci isolated from the wall of the bladder, one strain from an adjacent lymph-gland, and two out of five strains from the center of stones showed a marked affinity for the gall-bladder soon after isolation, and frequently produced no lesion elsewhere. Varying doses produced cholecystitis in nearly every animal injected. The severity of the lesions in the animals often corresponds to that found in the cases from which the strains are isolated. This affinity is soon lost, however, on cultivation as well as on animal passage. Five strains of colon bacilli, the one strain of typhoid bacillus, and one strain of the *Bacillus mucosus* in no instance showed any tendency to localize in the gall-bladder. It was not possible to produce cholecystitis with the streptococci by injecting them into the portal system, even with strains which produced cholecystitis practically every time when injected into the vein of the leg, and only localized cholecystitis developed at the point of puncture when the injection was made directly into the gall-bladder. In the animals which lived for a time, there was not infrequently observed the beginning formation of gall-stones containing numerous streptococci similar to the conditions found in several of the patients.

The strains of streptococci from the different cases show a striking similarity and resemble closely those from ulcers of the stomach. They produce either small, moist, grayish-brown or grayish-green, non-adherent, non-hemolyzing colonies on blood-agar; they ferment mannite, lactose and salicin; they produce short chains in liquid mediums with clumps of cocci somewhat resembling staphylococci; they are of a rather low virulence, yet somewhat more virulent than strains from gastric ulcers, as manifested by their resistance to phagocytosis, by the smaller dose necessary to kill, and by the fact that, when cultivated for a time, they acquire affinity for the stomach and duodenum while the strains from ulcers, when passed through one or two animals, acquire affinity for the gall-bladder at the same time as they lose affinity for the stomach.

On animal passage, two of the strains produced both cholecystitis and pancreatitis, the lesions in the latter being most marked in the head of the pancreas.

The lesions most commonly observed other than cholecystitis, when these strains are injected especially in rabbits, are: ulcer of the stomach, hepatitis about the gall-bladder, myositis and myocarditis, arthritis, appendicitis and colitis.

The common presence of streptococci in the wall of the infected gall-bladder and in the center of gall-stones, often in pure culture, while absent from the bile and their affinity for the gall-bladder in animals are strong evidence that streptococci are the cause of cholecystitis in man far more frequently than believed and serves to explain the good results reported by some as following cholecystectomy in cases of myocarditis, arthritis and other conditions.

END-RESULTS IN CASES OF GASTRIC AND DUODENAL ULCER *

ELLIOTT P. JOSLIN, M.D.
BOSTON

In 1899 Dr. Robert B. Greenough and I[1] reported on the condition of 187 patients with gastric ulcer treated at the Massachusetts General Hospital for the preceding ten years. We were able to show that "of 114 patients, 80 per cent. were discharged cured or relieved, but at the end of an average period of five years only 40 per cent. remained well." The mortality at the same time (due to gastric disease) was 20 per cent. Among the men it was 30 per cent., in women 9 per cent. The excessive mortality of ulcer among men, its occurrence in life a decade later than in women, and the absence of fatal cases of hemorrhage in women, point to a difference of the ulcer in the two sexes. . . . The failure of medical treatment to effect a lasting cure in 60 per cent. of the patients indicates the need of surgical intervention in other than emergency cases of this disease." These figures aroused wide-spread comment, because gastric ulcer had previously been considered a disease in which cure was the rule.

Fifteen years have intervened since the preceding compilation. Revolutionary changes have taken place in the knowledge and in the treatment of the disease. Duodenal ulcer is now considered as frequent in occurrence as gastric ulcer. Undoubtedly, in the previous report, a considerable number of duodenal ulcers were classified as gastric. In this series an attempt has been made to distinguish between the gastric and duodenal ulcers. This was difficult even with the knowledge gained in the operating-room. As a matter of fact, my personal division of the cases showed them to be within three of being divided equally. Surgery has wrought the other change in our attitude. Whereas, in the 187 cases occurring at the Massachusetts General Hospital in the ten years ending in 1898, but four patients were operated on, to-day operation is a common event. Justification, therefore, exists for another report on the end-results of treatment of duodenal and gastric ulcer, even apart from the fact that very favorable statistics concerning the present treatment of the disease are again being published.

---

* Read before the Section on Practice of Medicine at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

[1] Greenough and Joslin: Gastric Ulcer at the Massachusetts General Hospital, 1888-1898, Am. Jour. Med. Sc., August, 1899.

The purpose of this paper is to call attention to the outcome, after the lapse of many years, of a group of cases of gastric and duodenal ulcer. It is not the intention to emphasize the medical or surgical treatment, but to show end results. Some of the cases were treated by me, but as a rule they were seen in consultation with physicians. The medical treatment of ulcer is sufficiently well known but not sufficiently well carried out.

It has been possible to ascertain the present condition of 91 per cent. of all the cases seen by me in private practice during the last sixteen years. As the whole value of the paper rests on this fact, we are more than glad to take this opportunity to acknowledge that so large a percentage of cases could never have been traced without the persistence of my secretaries, Miss Helen Leonard and Miss Florence Newnham. I am also greatly indebted to Dr. Hugh P. Greeley, without whom the cases could not have been selected and analyzed and to whose critical judgment I owe much.

METHOD OF SELECTION OF CASES

All cases showing digestive symptoms of any kind from 1898 to date, including even gall-stone cases, were collected from my records and analyzed for this report. This was necessary because to-day duodenal ulcer would be recognized in cases in which it was not recognized ten years ago. A number of cases of duodenal ulcer were thus found which were not originally so diagnosticated. The basis on which the diagnosis of ulcer rested was (1) the history, with especial attention to the symptoms of hyperacidity, pain, hemorrhage, perforation, the duration of the case and the after-history; (2) the knowledge acquired by surgery; (3) necropsy reports.

The total number of cases was 234. Table 1 shows the number of cases seen each year.

TABLE 1.—NUMBER OF CASES SEEN EACH YEAR

Year	No.	Year	No.
1898	3	1908	14
1899	1	1909	8
1900	3	1910	15
1901	4	1911	28
1902	9	1912	30
1903	17	1913	31
1904	12	1914	8
1905	23		
1906	14	Total	234
1907	14		

The present condition of the patient in 213 cases, or 91 per cent., is known.

SEX; AGE; AT ONSET AND DURATION

The number of male patients was 142, and the number of female patients was 92. These figures form an interesting contrast to the Massachusetts General Hospital series before cited, for in that series there were 5 females to 1 male.

The average age of the male patients when first seen was 45 years and 2 months, but this does not represent the age at which the symptoms of ulcer began. The average age of onset of the ulcer in the males was 38 years and 8 months. The average age of the female patients when first seen was 36 years and 4 months, and the onset began at 30 years and 10 months; in other words, symptoms had existed for five years and six months, and at an age eight years earlier than that of the males. The statement is approximately correct that six years intervened between the onset of symptoms of all the cases and the time they first came for treatment. Undoubtedly this interval was greater rather than less. The duration of the disease in patients at present not relieved is eleven years. The duration in many cases was, in the patients' words, "as long as I can remember," but these could not be included in our tabulation because a definite time of onset was not known. The duration between onset and operation in thirty of the eighty-two patients surgically treated was ten years. In other words, the patients came to the surgeon, at an average, four years later than to the physician. The importance of the long duration of this disease cannot be too much emphasized. It lends support to skepticism about the high percentage of cures so frequently reported by physicians and surgeons. Twenty-one of the patients were 60 years old or over when first seen. One patient was successfully operated on at the age of 86, for which the entire credit is due to Dr. E. A. Codman, who, remembering the patient's indigestion, discovered the ulcer during an emergency operation for a twisted ovarian pedicle.

SYMPTOMS

The severity of the disease is readily seen from the frequency of severe symptoms. Vomiting was present in 147 cases, 63 per cent. Pain existed in 184 cases, 74 per cent. Hyperacidity, as shown by the symptoms, or in a large number of cases by gastric analysis, appeared 134 times, or 54 per cent. Hemorrhage was noted in 71 cases, 30 per cent.; but this figure is low because these statistics of hemorrhage were compiled from facts learned at the first examination, whereas, occasionally, hemorrhage occurred later for the first time. Hemorrhage was occasionally observed at a time after operation when the trauma of the operation could be excluded.

Perforation developed 9 times, 4 per cent. Six of these patients were operated on, and two recovered. Of the remaining 3 patients, 2 died and 1 recovered, to die five years later of pulmonary tuberculosis. This patient, following perforation, coughed up pus for a considerable length of time.

Stasis was present in 41 cases, 17 per cent. To me it was a surprising fact that 3 of these patients with marked stasis, after periods of nineteen, fourteen and ten years respectively, must be considered as relieved and yet without surgical treatment.

RESULTS OF TREATMENT

The results of treatment are classified under the headings of "At Present Well," "Relieved," "Unrelieved," and "Dead." The term "At Present" is inserted because in too many cases in which the patients are considered cured, the ulcer recurs. Undoubtedly, a considerable proportion of patients now well will later develop symptoms. The term "Relieved" in this paper is liberally interpreted. Many patients recorded as relieved are merely relieved, and acknowledge that this condition is only attained by rest and a careful diet. In this group are also included many who before reaching this improved stage had a recurrence of symptoms. The term "Unrelieved" is self-explanatory. Under the heading "Dead," care has been taken to avoid the error of crediting deaths to medical or surgical treatment when these were simply intercurrent and had no relation to digestive trouble. There were 11 such instances. Two patients died of pneumonia, two of cancer of the colon and two by accident, while apoplexy, tuberculosis, cirrhosis of the liver, brain-tumor and cancer of the breast each claimed one.

Medical Treatment: The total number of medical cases traced was 131, of which 51 patients are well at present, 55 are relieved, 16 unrelieved, and 9 dead. Three of the 51 patients now well have had a recurrence of symptoms after being first treated, and of the 55 patients relieved, 19 have had such recurrence. In other words, of the 131 medical cases followed to the present time, 39 per cent. of the patients were cured, 42 per cent. relieved, 12 per cent. unrelieved, and 7 per cent. dead.

The causes of death of the 9 medically treated patients were as follows:

Cancer of stomach 2, cancer of duodenum 1, perforation 2, of which one was a typical case of paroxysmal vomiting in a child, hemorrhage 2, and inanition 2.

TABLE 2.—RESULTS OF MEDICAL TREATMENT IN 131 CASES OF GASTRIC AND DUODENAL ULCER

At Present	Number	Per Cent.
Well	51	39
Relieved	55	42
Unrelieved	16	12
Dead	9	7
		100

Surgical Treatment: It would be manifestly unfair to report the results of the surgical treatment without emphasizing that:

1. A surgical case means a medical failure. In all of the 82 surgical cases the patients were operated on because medical treatment had failed.
2. Among the surgical failures are necessarily included two types of cancer cases—those cases of ulcer in which the patients die, after months or years, from cancer, and also cases in which there might be a difference of opinion as to whether these cases should have been excluded from the ulcer series on the ground that they were cancer from the outset or had become cancer at the time of operation.
3. Several of the cases of perforation were transferred to the surgeon at a time when the whole responsibility really rested on the medical attendant.
4. A number of patients were transferred to the surgeon for operation debilitated by inanition or prolonged hemorrhages.

In drawing my own inferences from the surgical treatment of the eighty-two surgical cases, I should deduct from the group of twenty-six surgical deaths nine cases of cancer of stomach or duodenum for example, one of these patients at 75 years of age with a history of ulcer of twenty years' duration, showed cancer when operated on by the surgeon. He was given complete relief by gastro-enterostomy for a year and three-quarters and died painlessly six months later, yet that case although surgically classified should not be considered a surgical failure. I would also deduct two cases of perforation, because they occurred at a time when, even without perforation, the patient was *in extremis*, and also one case because of inanition of the patient. It is true that twenty-six of the eighty-two patients operated on are now dead, but with the deductions which I feel are justified, this is reduced to fourteen, a surgical mortality of 20 per cent. In ten of the surgical cases, 12 per cent., the patients are still unrelieved. Thirteen, or 16 per cent. are relieved, though before reaching this half-happy stage after the surgical intervention, five had recurrence. Thirty-three, or 40 per cent. are now well, and of this number only three have had recurrence since operation. It will thus be seen that despite the handicaps which were heaped on the surgeon, his percentage of cures, 40 per cent., is approximately the same as that of the physician. If we discard the twelve deaths for which the surgeon might well not be held responsible, 47 per cent. of the surgical patients are well.

But I will now ask you to look at the matter from another point of view. If one should add all the surgical cases to the medical cases, for they were medical cases before they were surgical in this particular series, and then classify these surgical cases as medically unrelieved, we should then have 213 medically treated patients, of whom there are but 51, or 24 per cent., who recovered under medical treatment! The remainder, 162 patients, 76 per cent., were only partially relieved, unrelieved, dead, or forced into the surgeon's hands. It is my impression that this is the correct way in which to regard the medical treatment of gastric ulcer. In other words, medicine cures only approximately 24 per cent. of the ulcer patients, and of these there is a considerable chance for later relapse. Surgery helps out medicine and adds another 15 per cent. to those cured. In other words medicine and surgery together have given back complete health to 39 per cent. of 213 ulcer patients seen or treated by me in the last sixteen years.

TABLE 3.—RESULTS OF SURGICAL TREATMENT IN 82 CASES OF GASTRIC OR DUODENAL ULCER

At Present	Number	Per Cent.
Well	33	40
Relieved	13	16
Unrelieved	10	12
Dead	26	32

TABLE 4 (REVISED FROM THE FOREGOING).—RESULTS OF SURGICAL TREATMENT IN 70 CASES OF GASTRIC OR DUODENAL ULCER TREATED SURGICALLY *

At Present	Number	Per Cent.
Well	33	47
Relieved	13	19
Unrelieved	10	14
Dead	14	20

* This table was compiled from the foregoing table after the deduction of 12 deaths for which the surgeon was not responsible.

The causes of death in the surgical cases were as follows:

Cancer of stomach 7, cancer of duodenum 2, soon after operation 7, perforation 3, abscess of lung 2, empyema 2, pneumonia 1, pancreatic fistula 1, embolus 1.

It is noticeable that there is no case of jejunal ulcer; in fact, no patient with jejunal ulcer occurred in the series. In but five of the eighty-two cases was it necessary to operate twice.

The number of surgeons who operated on these 82 patients was 36. Two surgeons operated on 37 patients, and 4 surgeons on 15 others, while 30 patients were operated on by as many different men.

The type of operation was as follows:

Gastro-enterostomy	61
Infolding the ulcer, drainage, adhesions and exploratory laparotomy	15
Resection	3
Unknown	3

It is noticeable in how few instances the ulcer was resected. I must record that one of the severest cases was the one in which fully one-third of the stomach was removed, and this operation was one of the most successful of the group. The case is particularly interesting in that the reason for this extensive resection was due to the report of an eminent pathologist that cancer was present, but on the following day his careful study of the section removed revealed no cancer. It is not appropriate for the physician to comment on the type of operation. The physician has enough responsibility of his own in the treatment of ulcer of the stomach and duodenum.

In Table 5 the combined results of medical and surgical treatment are given.

TABLE 5.—COMBINED RESULTS OF MEDICAL AND SURGICAL TREATMENT IN 213 CASES OF GASTRIC AND DUODENAL ULCER OBSERVED DURING THE LAST SIXTEEN YEARS

Present Condition	Number	Per Cent.
Well	84	39
Relieved	68	32
Unrelieved	26	12
Dead	35	16

CANCER SUBSEQUENT TO ULCER OF THE STOMACH AND DUODENUM

Twelve, or 6 per cent. of the 213 patients have up to the present time died of cancer. The statistics on this point, however, are complete only for the forty-six patients now dead. Of these, 26 per cent. succumbed to cancer. In other words, one out of every four of the patients with ulcer of stomach or duodenum, which have been followed to their death, died of cancer.

CONCLUSIONS

1. In a study made of 234 consecutive cases of gastric and duodenal ulcer seen in private practice during the last 16 years, 213 cases, 91 per cent., were traced to date.
2. Of these cases 142 were in men, 92 in women.
3. The average age in men was 45 years and 2 months when first seen, but the age at onset was 38 years and 8 months. The average age in women was 36 years and 4 months, but at onset 30 years and 10 months. The average duration of the ulcer in the patients still unrelieved is eleven years; the average duration of the ulcer before the cases reached the surgeon, ten years.
4. There were 131 patients who were treated medically throughout, and of these at present 51, or 39 per cent., are well, 55, or 42 per cent., are relieved, 16, or 12 per cent., are unrelieved and 9, or 7 per cent., are dead.
5. Of the patients who were operated on when medical treatment had failed, 82 were traced and of these 33, or 40 per cent. are well; 13, or 16 per cent. are relieved; 10, or 12 per cent. are unrelieved, and 26, or 32 per cent. are dead.
6. Deducting 12 deaths for which the surgeon should not be held responsible there are 70 surgical cases in which 33 patients, or 47 per cent. are well; 13, or 19 per cent. relieved; 10, or 14 per cent. unrelieved, and 14, or 20 per cent. dead.
7. The combined medical and surgical results show at present: well, 84 patients, 39 per cent.; relieved, 68 patients, 32 per cent.; unrelieved, 26 patients, 12 per cent.; dead, 35 patients, 16 per cent.

GASTRIC CANCER IN THE YOUNG

A STUDY OF SIXTEEN INSTANCES IN PATIENTS UNDER THE AGE OF THIRTY-ONE *

FRANK SMITHIES, M.D.
Gastro-Enterologist to Augustana Hospital
CHICAGO

The sixteen instances of gastric cancer in the young forming the basis of this report were found in my study of the records of 721 pathologically demonstrated cases of cancer of the stomach at the Mayo Clinic and at Augustana Hospital. It is thought that their analysis will demonstrate certain facts of value in anticipating or detecting this grave malady at an age when it is not commonly suspected.

Those who wish to familiarize themselves with the literature on this subject may refer to the excellent monographs of Welch,[1] Osler and McCrea,[2] and Dock.[3]

A summary of previous reports on gastric cancer in the first three decades may be of service. Six instances (often rather dubious as to cancer) have been recorded below the age of 10. In the second decade, thirteen cases are described. In but eight of these were there reliable pathologic reports. In the thirteen instances occurring in the third decade, few descriptions are accompanied by pathologic findings. Many of the patients in this group, however, appeared to have been affected with a gastric malady, seemingly malignant.

INCIDENCE

The relative frequency of gastric cancer in the young varies with the individual series studied. In a small series, as, for example, the beautifully analyzed 150 cases of Osler and McCrea, the proportion was 4 per cent. In a large series, collected for statistical purposes from various non-related sources throughout the world, as in the 2,038 instances tabulated by Welch, the ratio is 2.8 per cent. In my own group of 721 consecutive cases, examined by a uniform method (and a distinctly American experience), the percentage was 2.2 per cent.

Sex: There were nine females and seven males. Age: The youngest patient was aged 18; the oldest just past 30 years. The average age of the series was 27.8 years. Status: Twelve patients were married. In two instances (12 per cent.) there was a family or blood-relationship history of cancer. Only twice were more than ordinary indulgence in tobacco or alcohol noted. Apparently occupation had no eitologic significance.

DURATION OF ALL GASTRIC COMPLAINTS

Most useful facts are brought out by study of this phase. The shortest time was four months, while in one instance the gastric disturbance had persisted for fifteen years. The average length of time of the disability was 4.2 years.

Consideration of the earlier part of those histories in patients exhibiting protracted gastric complaints not infrequently reveals the fact that there is in the early stages a different clinical presentation of the disease than is exhibited towards its end. It would seem that the observation of occasional cases of cancer in which the duration of the gastric history had been long drawn-out, doubtless led such clinicians as Dock[3] and Mathieu[4] to venture the opinion that cancer of the stomach in early life runs a somewhat slow course. This opinion appears well-founded if one considers both the "pre-cancerous" and the evidently cancerous portions of the history.

TYPES OF GASTRIC HISTORIES

In respect to types the histories divide themselves quite sharply into two groups: Group 1 includes cases in which there appeared a gastric affection, pernicious in nature and progressively downward in course, in patients in whom there had been no previous gastric ailment. Group 2 comprises a number of cases in which, previous to the time at which they came under observation for a gastric disease of a malignant kind, there had been gastric complaints which frequently conformed to the type which we call clinically "peptic ulcer."

Group 1.—Two of the sixteen cases studied fall into this class. The average duration of all symptoms was 4.5 months. In these two cases the disease was from its inception progressively and perniciously downward in course and type, and there was no alteration in the character of the affection. There were, clinically, rapid emaciation, continuous abdominal discomfort, early onset of vomiting, development of epigastric tumor and departures from the normal in the test-meal analysis. Laparotomy revealed large, inoperable growths, with extensive involvement of the lymph-nodes and pancreas. One patient died within twelve days following operation; the other lived a year.

Group 2.—This includes fourteen cases. These patients had been affected for an average time of 4.8 years with some gastric malfunction. In type the early part of their affection had been roughly classed among the "dyspepsias." A careful analysis of the character of these dyspepsias reveals useful facts. In five instances (36 per cent.) the gastric complaint and course had fully satisfied the symptom-complex which we ascribe clinically to peptic ulcer. In four cases (25 per cent.) so-called ulcer features were definite at some stage in the early period (in one instance in this group there was frank gastric hemorrhage). In four other cases (25 per cent.) the long-term history previous to onset of evident malignancy was that of peptic ulcer of irregular type. In the remaining case gall-stone attacks were typical through four years, and the stones were later found at laparotomy.

The second part of the histories of cases making up Group 2 was typical of gastric malignancy. While this phase differed widely in character from the early manifestations, yet it could in nowise be distinguished clinically from the whole course of the ailment in the two cases making up Group 1. If one had not carefully analyzed the early histories of these fourteen cases in Group 2 he could have in no way showed their clinical variation from cases in Group 1. The period of evident malignancy in Group 2 averaged 7.8 months in duration. The most rapid progress was three weeks; that most extended nearly three years.

It might be useful to emphasize the fact here that of this group of gastric cancer cases in the young with long-time histories, 86 per cent. satisfied or approximated our present-day clinical complex of peptic ulcer at some time during a period averaging 4.8 years, previous to the time when the course became malignant; that during this time medical treatment availed nothing and the surgical opportunity for cure was usually neglected; that the cases in this group, due to some unknown cause, did not pursue a course of chronicity of benign type, but later evidenced malignant pointings, and that the malignant course of the cases in this group exhibited an average duration nearly half again as long as occurred in cases of Group 1 in which no previous gastric disorder had been observed.

CLINICAL DATA

Appetite.—In six instances (38 per cent.) the appetite was poor. In the remaining cases it was usually fair.

Bowels.—All cases exhibited some degree of constipation.

Weight Loss.—In the two instances of short-term cancer, (the so-called "primary cancers"), the average loss of weight was 17 pounds. In the early period of the group of cases with long-term histories, weight loss generally occurred during the "spells" of the disability, but was rapidly regained during the succeeding quiescent stages. In some of these spells the weight loss ran as much as 35 pounds. In the late stage of cases of this type (the malignant period) the weight loss averaged 31 pounds. It was continuous and accompanied by other evidences of cachexia. Some rapid weight losses were observed, namely, 20 pounds in two weeks.

Abdominal Pain or Distress.—In some degree, this was noted in all patients. It was commonly located indefinitely in the epigastrium, but occasionally the complaint was of distress in the back or the high "pit." In two instances pains of so severe a degree and of such spasmodic character were noted that perforation was believed to have taken place.

In the two cases comprising Group 1 above ("primary cancers") the pain was never severe, never definitely localized, was continuous, but was generally aggravated by the ingestion of food or drink. In these instances the common pain relief was obtained by limiting the amount of ingested food, vomiting at the height of distress, and, occasionally, by alkalies.

Of the fourteen cases included in Group 2 above (those in which the patients had had gastric distress before malignancy became evident), twelve (85 per cent.) had pain in "spells" or "attacks." In seven instances, the pain at such times had borne fairly definite relation to food ingestion; in four instances, even when malignancy had supervened, the food relief of pain persisted. In ten cases former food relief of pain had changed to food aggravation of pain, as the malignant process became manifest. In this group of fourteen cases the common modes of pain relief were vomiting, lavage, limited or varied diet, alkalies, food intake and some form of opiate.

Abdominal Tenderness.—This was exhibited on palpation in all instances. In 38 per cent. it was located generally in the epigastrium. In three instances, the maximum tenderness was in the left epigastrium. In rare instances was abdominal tenderness, such as is characteristic of chronic ulcer of the perforative type, noted even when laparotomy showed that the peritoneum had become extensively involved.

---

[4] Mathieu: Semaine méd., 1895, p. 225.

Epigastric Tumor.—Tumor was palpated in six cases (38 per cent.) in the entire series (See Table). In but one instance was a large mass demonstrable. In the cases presenting no definite tumor, peculiar stiffness of the abdominal wall with a sense of deep resistance was frequently observed.

Four times free fluid was shown to be present in the abdominal cavity before laparotomy. These were inoperable cases. In three, metastases, as in the left supraclavicular region and pelvis, were noted before operation. These patients had hopeless involvement.

Eructations and Pyrosis.—These were commonly noted, particularly when gastric motility had been interfered with.

Vomiting.—Vomiting, with or without nausea, was observed in all the cases at some time (usually in the terminal stage) in the course of the disease. In the two "primary cancers," vomiting came on daily soon after taking food, was large in quantity, rancid in odor, but never "coffee-colored."

In the fourteen instances in which malignancy had terminated a long-term gastric history, vomiting occurred from one to eight hours after meals; in but one instance was it "coffee-colored;" in all instances it contained food particles, was of a rancid odor and relieved abdominal distress. In eight cases "delayed" vomiting was observed. Such sign was usually associated with pyloric stenosis and huge, dilated stomach.

LABORATORY DATA

Blood.—In the fourteen instances in which the hemoglobin was estimated, it averaged 66 per cent. The range was from 25 per cent. to 70 per cent.

Stool.—In ten instances (62.5 per cent.) altered blood was chemically demonstrated by the benzidin or the guaiac tests.

Test-Meals.—In fifteen instances facts of much interest were obtained by this mode of examination of gastric function. One case returned no information by test-meal analysis because the stomach-tube could not be advanced beyond the cardia. There was obstruction due to extensive local growth.

Gastric Emptying Power.—In eleven cases (73 per cent.) motility was interfered with and there was retained food at the end of twelve hours. In such instances, dilatation of the stomach of various degrees had invariably occurred.

Gastric Acidity.—In no case was achylia shown. The average *total acidity* was 59. It ranged from 28 to 64.

Free hydrochloric acid was absent in but one instance. This was a case of fulminant, primary cancer. The average free hydrochloric acid estimation for the entire series was 26. It ranged from as low as 3 to as high as 60. The highest free hydrochloric acidities were noted in association with large, cancerous ulcers.

Combined hydrochloric acid and acid salts averaged 18.1. It ranged from 0 to 50.

Lactic acid was demonstrated by the modified Uffelmann test in six cases (40 per cent.).

Altered blood was proven by chemical test in gastric contents twelve times (80 per cent.).

Microscopic Examination of Unfiltered Gastric Extracts.—In but six instances (40 per cent.) were organisms of the Boas-Oppler group definitely identified. In eight cases (53 per cent.) yeasts and sarcinae were present. Microscopic food bits were recognized in nearly 90 per cent. of instances.

THE LAPAROTOMY FINDINGS

Two cases had been explored before coming to us. Both the patients had been operated on within the year. At both abdominal sections the surgeon had made a clinical diagnosis of "benign" gastric ulcer of the chronic type, yet both of these patients were dead from inoperable, general cancer *before a year had elapsed!* The resection of the ulcer or the microscopic examination of a bit of extirpated tissue at the time of the initial laparotomy doubtless would have made known earlier the prognosis and have prevented further surgery. It might have saved life.

Location of the Malignant Process.—Abdominal section revealed five instances in which the pylorus was involved; nine cases in which the lesser curvature and some part of the surface of the viscus were affected; one instance of infiltration at the cardia, and one case of general carcinosis.

Lymph-nodes had been invaded in fourteen out of the sixteen cases in this series. Nine times secondary growths were demonstrated in the liver, pancreas, omenta or pelvic organs.

Character of Neoplasms.—In eight instances, extensive ulcera carcinomatosa were present. They were of the medullary type. In the remaining cases, adenocarcinomatosa of the common type were demonstrated.

OPERATIVE PROCEDURES AND OUTCOME

In four instances exploration only was possible. In five cases some form of resection was performed with or without gastrojejunostomy. In the remaining seven patients "drainage operations" to fit the case at hand were devised.

Nine patients died within one and one-quarter years following operation. To the other patients of this series was granted a lease of life of from two to more than five years.

122 South Michigan Boulevard.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. JOSLIN AND SMITHIES

Dr. J. N. Hall, Denver: There are certain chances of error in the diagnosis of gastric ulcer that do not come to one's attention unless the cases come to operation. In case hemorrhage occurs it draws attention to the possibility of ulcer and makes the diagnosis easier. I recently had a case showing pain, hyperacidity and distress and I found that the patient had had trouble ten years before. I believed that this was undoubtedly a recurrence, and had expressed that opinion to the surgeon. At exploratory operation we found the marks of an old ulcer 4 or 5 inches from the pylorus, a condition which it would have been impossible to diagnose without operation. The acute symptoms were caused by a chronic intermittent pinching of the pylorus in a Treitz's hernia which caused the blood to leak through into the stomach. In another case there had been a long-continued history of gastric symptoms in a patient who came from the country and who was a hard drinker; when I saw him he was nearly moribund from a violent hemorrhage believed to be from ulcer. I found it due to a thrombosis of the superior mesenteric artery, associated with cirrhosis of the liver which had followed alcoholism. In another case there was a chronic pinching of the superior mesenteric vessels under the root of the mesentery. For a long time there was slow bleeding, leading us to believe he had an ulcer, but none was found. I have seen two or three cases from three to six months after appendicitis with symptoms of ulcer caused by dragging down of the pylorus by the omentum. Some of these cases have obscure and continuous pain and it is difficult to figure them out. Time and again, I have found a minute hernia, not larger than a grain of wheat, and these slight hernias often give the symptoms of pyloric ulcer. This is probably caused by chronic reflex irritation of the stomach which continues until symptoms of ulcer appear. Again we see patients with the severe pain associated with ulcer, and with jaundice. Two or three operations have been performed with the idea that we were dealing with gallstones, because of the pain and jaundice, and the surgeon was chagrined when the real condition was found to be duodenal ulcer. In such cases the large duodenal ulcer had spread and compressed the common bile duct.

Dr. F. B. Lund, Boston: Dr. Joslin's paper gives a good idea of the ultimate results in surgery of the stomach. I do not think, however, that he ought to speak of a surgical mortality of 20 per cent. in gastric ulcer without making it plain that that is not the operative mortality. The operative mortality in my own cases is 5 per cent. The function of the surgeon in gastric ulcer is to interfere in cases which have resisted medical treatment and alter the conditions so that the ulcer may heal. This good end is accomplished in from 60 to 80 per cent. of the cases that are operated on. I understand that Dr. Joslin reported a case of duodenal ulcer in which the patient died in the sanatorium six months after the operation, as a surgical death. To my mind, this was not a surgical death, but a surgical failure; surgical interference failed to cure the ulcer and the patient died in six months, not because of, but in spite of it. Only those who die while still in hospital should be called surgical deaths. This, of course, would make the surgical statistics look very much better.

Dr. Frank Billings, Chicago: I think Dr. Joslin's statistical paper is only of relative value. Dr. Joslin acknowledges that the diagnosis of ulcer was not made in some of the earliest cases seen and that some of the patients were seen only in consultation. Therefore, there may be a question of diagnosis in some of the series. Thirty surgeons operated on thirty patients. How many physicians managed the medical treatment? What operations were performed? What was the medical management? If medical treatment failed, why? Of what did the patients surgically treated die? My experience is that ulcer of the stomach is usually mismanaged medically by the average practitioner. Statistics, to mean anything of value, must be more explicit in details of both medical and surgical treatment.

Dr. J. A. Lichty, Pittsburgh: It seems from Dr. Joslin's paper that neither the medical nor surgical treatment of ulcer is altogether ideal. From his paper we learned that 43 per cent. of the 213 cases were supposed to be cured. This is, of course, a low percentage of cures in a condition which is, after all, not so frequently fatal. This may be explained by the facts submitted. It seems the patients were not seen by the internist until the ulcer had run a course, on an average, of five and one-half years, or by the surgeon until the ulcer had run a course, on an average, of ten years. It is to this part of Dr. Joslin's paper I wish to direct attention—the necessity for early recognition of gastric and duodenal ulcer. The low percentage of cures is due more likely to the length of time which expires before any proper treatment is undertaken. The irreparable damage occurs before the internist sees the patient and not during the interval between the internist and the surgeon. In other words the patient likely lost his chance for cure before either internist or surgeon saw him. This is a difficult problem to meet. It is not always the fault of the physician. The patient will carry soda-mint tablets and alkaline powders for years before consulting a man who is capable of diagnosing gastric or duodenal ulcer, and it is not the fault of the laity alone; even physicians themselves in their own cases pursue the same course. In our teaching in medical schools, the symptoms of so-called "dyspepsia" should not be considered lightly, but should be looked on always as the evidence of some pathologic condition until the contrary is proved. If all the means at our disposal are employed it is not so difficult to make a diagnosis in early cases of acute or open ulcer. It is only after ulcers have been present for some time that they become so difficult to diagnose. We have now many tests, as for occult blood in the stools, the string test, roentgenoscopy, gastroscopy and others. If all the tests are employed and the patient's history carefully studied the diagnosis can be made easily in the early cases of open ulcer. I am sure this 48 per cent. of cures can be brought up also by teaching the laity to apply early for treatment in cases of gastric disturbance. If patients are seen during the first month or during the first two or three, or even five months, and proper medical treatment is instituted, I am sure more than 48 per cent. will get well.

Dr. Alexander Lambert, New York: Did Dr. Joslin try to calculate the end-results with the two surgeons who had 34 cases and the thirty surgeons who operated in the 30 cases? What was the difference in results between those who were in the habit of performing these operations and those who performed them relatively infrequently? It is known that the gastro-enterostomy opening into the stomach is apt to close if the pyloric opening remains patent. It is only when the pylorus is definitely stenosed that the gastro-enterostomy remains open. If 45 per cent. of the patients operated on, and about 50 per cent. of all patients treated medically remained unimproved, it must show that neither medically nor surgically have we worked out a successful treatment for these chronic ulcers of the stomach. Of course there is no question that in those old chronic ulcers in which there is scar tissue and a stenosis or deformation around the pylorus and a definite mechanical obstruction at this point, surgical procedure is the only method by which relief may be obtained. In other chronic ulcers, however, without the deformation of the stomach, so many different kinds of medical treatment have been tried that it is impossible to say, by any given set of statistics, whether or not really purposeful medical treatment had been accurately carried out. Until we are able to answer the questions of etiology of duodenal and gastric ulcer and base our treatment on this knowledge, it does not seem to me that we will be able to obtain much better results than those that are reported by Dr. Joslin, for if medical treatment gives but 39 per cent. of so-called cures and surgery gives but 45 per cent., there is such little difference between these results that it cannot be said that either one or the other offers much advantage, and neither medicine nor surgery has, as yet, worked out a proper method of treating these ulcers of the stomach and duodenum.

Dr. F. A. Speik, Los Angeles: What Dr. Billings and Dr. Lambert said is true. Patients do not pay enough attention to the early symptoms of ulcer, but it is also true that the physician whom they consult early does not work hard enough to determine whether the diagnosis should be of gastric and duodenal ulcer. Diagnoses are made of indigestion or dyspepsia and the patient is put off with palliative treatment. Many of Dr. Joslin's cases came to him eight or nine years after the onset. They surely consulted some physician before they did him, but the correct diagnosis was not made. Dr. Joslin's medical failures are not due to incorrect medical treatment, but they are due to the lack of early recognition, and therefore due to the lack of proper treatment. Many of his cases presented surgical complications when they came to him. Surely he cannot call all surgical cases medical failures, because not only are the ulcers not recognized and not treated, but also many are latent until some such surgical complication as mechanical obstruction, perforation, perigastric adhesion, etc., takes the patient to the physician. These must be recognized as surgical cases and not treated medically. There are definite indications for medical treatment and relative and absolute indications for surgical treatment. The surgical cases are those that may be relieved mechanically, such as perforation, which demands immediate diagnosis and operation, pyloric obstruction with actual cicatricial narrowing, with obstruction of high grade (but pyloric closures due to inflammatory swelling and spasm are medical cases), perigastric adhesions, hour-glass stomach, etc. Hemorrhage in 97 per cent. of the cases calls for medical treatment. In a medical case a gastro-enterostomy does not necessarily heal the ulcer. If the pylorus is patent the gastric juice will continue through it and take off the granulation tissue and the ulcer does not heal. In Dr. Sippy's clinic, motor meals on the gastro-enterostomized stomach show that the stomach does not empty itself faster than normal. Our failures in gastric and duodenal ulcer are due to the lack of early diagnosis and the lack of an energetic medical treatment. The medical man should work harder to make the early diagnosis of ulcer and should also pay more attention to detail in his treatment; then there will be fewer medical failures.

Dr. Allan A. Jones, Buffalo; There should be no unpleasant contention between the medical and the surgical men with respect to the care and treatment of gastric and duodenal ulcer. I often wish that medical men could operate, not that they would operate so often as surgeons do, but that they might apply this form of mechanical therapeutics. What is surgery but mechanical therapeutics? It is not a question of medicine or of surgery but of the accurate diagnosis in a given case at a given time and in a given condition. If the patient does not make satisfactory progress under medical treatment then one should resort to surgical treatment. Statistics are apt to be misleading and are sometimes useless, but if Dr. Joslin's paper shows anything it is that our best results follow medical treatment, but that at the proper time and under proper conditions surgery must be chosen. So far as the results of medical treatment in gastric and duodenal ulcer are concerned, the real and only valuable statistics we could compile would be compiled by personal supervision of every patient in the hospital kept under the immediate care of special nurses, as the control of the diet is most important. It is difficult to control the patient's diet when he is out of the hospital. Von Leube, some years ago, reported 556 cases in which the treatment consisted of absolute rest in bed, a milk diet, the application of poultices over the epigastrium and the administration of little or no medicine, and in these there were 95 per cent. of cures. I do not know the end-results in this series of cases, nor do I know how many recurrences there were, but there was probably a large number. The study of the end-results in a series of cases, as made by Dr. Joslin, is timely and important.

Dr. J. R. Verbrycke, Washington, D. C.: I call attention particularly to the thread test, the benzidin reaction for occult blood and the roentgenogram. With a few exceptions I hold the clinical history subservient to these tests. A thread smeared with blood does not always positively indicate an ulcer, but small localized spots always in the same place on several threads has in my experience been almost infallible. I rarely make a positive diagnosis of ulcer without a positive benzidin reaction. When we learn the value of these tests as well as their limitations, we will make much earlier diagnoses and so secure better end-results. I am still finding more gastric than duodenal ulcers. The number of duodenal cases has markedly increased, but through our increasing facilities for diagnosis the gastric ulcers have kept pace. By the thread and the roentgenogram—the only reliable means of localization—I am finding many to be on the lesser curvature and have encountered about thirty in that location in the past two years. The localization of ulcer is important both for prognosis and for the treatment. A duodenal ulcer operated on with gastro-enterostomy and closure of the pylorus usually gives spectacular results, while, on the other hand, ulcer of the lesser curvature may not only be cured by operation but the symptoms may be aggravated unless the ulcer is excised. Our criterion for cure should be just as strict as our endeavor is earnest to make a diagnosis in the first place. It is not sufficient that the patient does not have symptoms. I always have the patient report, after his treatment, once a month for a year bringing a specimen of stool to be examined for occult blood. Occult blood often appears months before a return of subjective symptoms. If the patient has no return of symptoms or occult blood for twelve months, we can call him cured.

Dr. Anthony Bassler, New York: Until more is learned of the etiology and pathology of ulcers, statistics on results of treatment will be useless. To say so many ulcers have been treated either medically or surgically and to give results without discussing the etiology and the varied pathology of ulcers is holding the subject back. I think that Dr. Joslin's statistics present too few cures by both the medical and surgical methods of treatment. I agree with Dr. Billings and Dr. Lambert; the subject cannot be presented *in toto* from the medical or the surgical side alone. The unfortunate status of affairs in this condition makes one case of ulcer in which the etiology and pathology have been worked out of more worth than statistics on a thousand treated in which neither one of these is mentioned. It is probable that so far as results from treatments are concerned, division can be made between soft and hard forms, for in my experience it depends on the absence or presence and extent of fibrous tissue and the character of cell infiltration whether medical or surgical measures are successful. Our knowledge of etiology, the old divisions of pathology, the overusing the length of clinical course for differentiation between acute and chronic forms, and even the revealments of the operating-room are still far short of what we must learn properly to understand gastroduodenal ulcer.

Dr. George Douglas Head, Minneapolis: How long a time have these operated patients been under observation subsequent to operation? We all know that the history of gastric and duodenal ulcers is one of remissions and exacerbations. A tremendous amount of statistical material has been brought to our attention from the surgical clinics during the last few years purporting to give the operative end-results of gastric and duodenal ulcer after one, two or three-year periods. In discussing the cure of gastric and duodenal ulcer, we as medical men are thinking in the terms of five, ten or even more years and our statistics are based on these figures, while the surgeons are giving their results in terms of one, two, or at most five-year periods. No surgical statistics exist showing the results of operative treatment over a ten-year period. In order intelligently to compare the end-results of the surgical and medical treatment of gastric and duodenal ulcer the same standard of time interval must be adopted by both surgeons and internists. Over how long a period of time were Dr. Joslin's series observed subsequent to operation? We must not deceive ourselves in the analysis of statistical material offered in proof of one method or the other for the cure of gastric and duodenal ulcer. We must approach the whole subject in a broad but scientifically critical spirit.

Dr. J. D. Dunham, Columbus, Ohio: The occurrence of gastric cancer in patients under 30 years of age is quite infrequent. I have seen three, in two women and one man, aged 18, 24 and 30 years, respectively. In every instance there was increased hydrochloric acid and the total acidity was increased. All were of the fulminating type. All three cases were proved by operation and histologic examination of the specimens to be true cancer.

Dr. M. H. Fussell, Philadelphia: I have not heard a word spoken of indigestion; it has probably been purposely left out. Yet I would venture to say that practically every patient whom Dr. Joslin has seen was treated for indigestion long before it was thought that the condition was gastric or duodenal ulcer to be treated either medically or surgically. Many cases will continue to be treated for flatulence, epigastric pain and disturbance and for indigestion until they are far beyond hope from medical treatment and in many cases from surgical treatment. It is a fact that numerous conditions bring about symptoms which are called indigestion. The functional cases of indigestion are not due to any surgical condition whatever. In such conditions as gastric ulcer, infectious gall-bladder disease, chronic appendicitis, carcinoma, and others, the true condition is often not recognized until the patient is far beyond the help of either medical or surgical treatment. When one sees a patient with what is commonly called indigestion, that patient should be gone over carefully from head to foot to find out just what is the matter. Then treatment should be according to the indications. I think we are entirely unjustified in treating these case with alkalies and other internal remedies for months and years until they become difficult to diagnose. It is not the early cases as described in the text-books that are hard to diagnose but the border-line cases. When a patient has been given all the advantages of medical treatment and does not improve it becomes our duty, after a reasonable period, to have an exploratory operation to find out what is the matter, for an exploratory operation is less dangerous than long-continued medical treatment that is giving unsatisfactory results.

Dr. J. M. Rector, Columbus, Ohio: I agree with Drs. Joslin and Smithies in emphasizing the importance of early diagnosis in these conditions of the stomach. I would also call attention to Dr. Vaughn's theory of infection as it relates to the causes of gastric ulcer, and to recommend the trial of certain therapeutic measures before a gastro-enterostomy is determined on. In Dr. Vaughn's theory it is shown that a ferment caused by bacteria infesting the mucosa attacks the mucosa destructively, whereon the body cells, if the cell resistance of the host be sufficient, begin themselves to produce ferments to overcome and destroy bacterial ferments. Thus the resistance of the patient becomes a factor, and the drainage and motor function of the stomach important considerations. In case of interference with drainage, I wish to urge a serious attempt to restore the elasticity and tone of the gastric muscles by pneumatic gymnastic methods before such a measure is resorted to. As Cannon points out, "The essential fallacy in the idea of gravity drainage from the stomach results from a failure to regard the pressure relations in the abdominal cavity. The weight of the alimentary canal, as such, is approximately that of water. The food swallowed or undergoing gastric digestion has approximately the weight of water. The pressure in any part of the inactive alimentary canal, as Weisker proved, is due to the weight of the overlying abdominal organs. If the canal is inactive, therefore, the food is as if surrounded by water. Water resting in water is, of course, in exact equilibrium, and even when the body is in the upright position, and a large artificial opening connects the stomach and the intestine, water will not run out; 'because of the hydrostatic relations in the abdomen, gravity can have no effect.' 'Drainage' in the common usage of that term is therefore impossible. That the food may move onward through the alimentary canal, muscular contraction is necessary to create a difference of pressure." If gastro-enterostomy is done when gastric tone is deficient, it will fail because there can be no drainage without muscular contraction. This is the explanation of "vicious circle," and the reason for the undoing of many gastro-enterostomies.

Dr. Elliott P. Joslin, Boston: I agree with Dr. Lund that if the surgeon gets his cases of gastric and duodenal ulcer in a favorable condition he may obtain from 90 to 95 per cent. of recoveries. Dr. Lichty hit the point when he said that cases of ulcer would do better if treated early. In my series of 213 successive cases, there was an average history of six years of discomfort before seeking treatment. I hope no one else will report a series of cases coming to treatment after having suffered so long. I purposely did not attempt to draw comparisons between the thirty patients operated on by thirty surgeons and the thirty-seven operated on by two surgeons, because the number was too small. Probably four-fifths of the surgical cases were treated during the last three or four years; consequently the surgical end-results showing 47 per cent. of cures cover a far shorter period of time than do the medical end-results. The statistics, therefore, are favorable to the surgeon. Dr. Billings criticizes the value of these statistics because the cases have been treated by many medical men and necessarily (?) show very poor results. In the last series of cases which I reported some sixteen years ago, with Dr. Greenough, the criticism was likewise made that the results were unusually poor. In that series 114 cases were reported and it was stated that 80 per cent. were discharged from the hospital cured. At that time the Massachusetts General Hospital was under the dominating influence of two of the best men in medicine in America—F. C. Shattuck and R. H. Fitz—and there is no doubt but that these men carefully treated the patients with ulcer of the stomach. Yet when we came to analyze the 80 per cent. of cures and ferreted the patients out after five years, we found that only 40 per cent. were well or even relieved, quite as in this recent series. There is little doubt that if Dr. Billings studies the records of the Chicago hospitals, he will find 80 per cent. of the patients with ulcer of the stomach or duodenal ulcer have been discharged as cured, but if he should be able to follow 91 per cent. of the series after five years have elapsed, he would probably discover that the percentage of cures had dropped far below that figure. Is it not proper to ask Dr. Billings to present a similar series of 234 or more cases of gastric and duodenal ulcer and to trace out the end-results of 91 per cent. of them after a period of five years? Should this be done, I think he would allow that our statistics are correct. In the paper we did not attempt to discuss the medical treatment of ulcers, but rather to show what happened to patients who had had the disease, in the hope that we all might treat our patients better.

Dr. Frank Smithies, Chicago: The whole subject of gastric ulcer is in a state of transition. Confusion arises from medical men trying to interpret surgical statistics, and vice versa. The life history of chronic peptic ulcer is one of periodicity of symptoms and signs. It is a disease prone to recover and recur, seemingly quite irrespective of what type of medical treatment we use. Many cases called "medical gastric ulcers" have been shown by laparotomy not to be ulcers at all. This is especially true in persons under 30 years of age. In these patients, practically the same clinical picture is presented when the lesion is in the appendix or gall-bladder. In this event pyloric spasm, and vagotonic hyperacidity are responsible for the discomfort. Unfortunately, the statistics of peptic ulcer have been confused by this false ulcer group. "Medical ulcers," so-called, do, however, occur. They are apparently, in their life history, quite a different pathologic process from the chronic ulcer. Hence, this type of ulcer cannot in any way be compared, statistically, with the "surgical" ulcer. A medical ulcer is something that can rarely be seen or felt and manifests itself only by its symptoms, whereas, a "surgical" peptic ulcer can be seen and felt, examined pathologically, and definitely described and recorded. It would seem that Dr. Joslin is quite justified in giving the statistics that he has presented. It shows us our limitations in the subject. He has gone quite as far as possible in the comparison of things, which, from their different clinical and pathological nature, it is impossible to compare. Concerning the value of the occult blood-tests and the "string test," both these maneuvers may lead us to make grave mistakes, unless carefully checked. I have used three hundred strings. In 167 instances, peptic ulcer was proven operatively. In but seven instances were the findings suggestive of a "positive" string-test. When it is recalled that ulcers only bleed intermittently, it will be seen what a factor of chance there is in relying on this test for useful, clinical information. Tests for blood in the feces by means of guaiac or benzidin must be very carefully interpreted. Patients on a meat-free diet may give typical reactions if they are eating chlorophylaceous vegetables, or food rich in iron compounds.

Black Versus White Operating Sheets.—Black and white operating sheets are compared in the 1913-1914 "Report of the Medical and Sociological Departments of the Colorado Fuel and Iron Company" as follows: "The advantages of a dark sheet are: It absorbs light, rests the eye, and the predominating reflection is from the wound. The disadvantages of the white sheet are: It reflects strongly, tires the eye and produces feeble contrast. It is contrast that is desired. The dark sheet is to the surgeon what the dark room is to the ophthalmologist."

LANDRY'S PARALYSIS

REPORT OF A CASE, WITH NECROPSY *

EDWARD D. FISHER, M.D.
NEW YORK

Many cases have been reported since Landry first described a disease characterized by a rapidly ascending paralysis passing from the lower to the upper extremities, thence to the cranial nerves, causing various paralyses, and ending fatally in the course of six or seven days with involvement of the vagus and respiratory failure. The pathologic changes in the early cases were negative. This may have been due to the insufficient methods of examination in part, but even in later reports very few changes have been found at times, as in the case fully reported by Pfeiffer,[1] in which changes in the peripheral nerves only were found to be present.

In the literature of this subject, which is considerable since Landry in 1859 described his case, we find various lesions recorded in which either polyneuritis or spinal cord or bulbar inflammatory involvement has been present, or all in combination. Leyden and Goldscheider hold that it may assume any or all of these forms. The cord changes are usually hyperemia, perivascular infiltration and hemorrhage; at times interstitial neuritis. All authors agree that it is of infectious origin and attempts have been made to isolate a specific organism.

The case I shall record may be of interest, as it was observed from the onset, and a careful post-mortem examination has been made.

History.—W. E., boy, aged 15 years; previous history negative. Sept. 27, 1913, he complained of pain and weakness in the lower extremities, which increased in severity until October 11, when he was admitted to St. Vincent's Hospital, in New York, in the service of Dr. Constantine J. MacGuire. Examination of the heart and lungs and abdominal organs was negative. There was paralysis of the lower extremities, with loss of reflexes and tenderness over the larger nerve trunks. No anesthesia.

Laboratory Findings.—The urine was negative. The spinal fluid was clear; Fehling's reduction test was positive; the globulin was slightly increased; cells were 7 per c.mm. Smears and cultures for bacteria were negative. The Wassermann was negative; throat cultures negative. An examination of the blood showed 23,500 white cells, with 86 per cent. of polymorphonuclears, 2 per cent. of transitionals and 12 per cent. of lymphocytes. October 17 there was paralysis of the external rectus of the left eye. The eye grounds were negative.

Course.—The weakness gradually extended to the upper extremities, with loss of power, which in the course of a week became complete in the hands and arms. October 29 there was difficulty in swallowing and complete paralysis of the muscles of the right eye and of the superior oblique of the left eye (Dr. Kelly). November 7 there was dyspnea and difficulty in swallowing. All of these symptoms gradually increased in severity, and death occurred November 21 from respiratory failure.

Necropsy.—The necropsy, macroscopically, showed intense congestion of the cord; no other lesion. Microscopically, there was an interstitial neuritis of the sciatic nerve and congestion of the anterior horns, without perivascular infiltration or meningeal involvement. The medulla showed involvement of the cranial nerve nuclei and degeneration of the axis cylinders for a short distance from the cell body. The whole picture differentiated it from poliomyelitis. The brain, at the time of this report, had not been examined. The microscopic study of the case was made by Dr. John H. Larkin.

CONCLUSIONS

We have here, therefore, a case of ascending paralysis, with attending neuritis, which followed the usual course of extension, later involving the upper extremities and the bulbar nerves, resulting in respiratory failure. The pathologic findings are definite, involving both the peripheral and central nervous systems. The course of the disease was longer than that usually described, extending over six weeks, but otherwise the case was typical in its clinical manifestations.

46 East Fifty-Second Street.

ABSTRACT OF DISCUSSION

Dr. Walter B. Swift, Boston: The great question in this field of investigation, as everybody knows, is whether or not Landry's paralysis and anterior poliomyelitis are identical disease-entities. It seems strange that, as the years go by and these cases of Landry's paralysis appear, no one takes the crucial step that is to result in determining this point. The research that would do it is this: Emulsify the cord from a Landry's paralysis patient and inject it into a monkey. If the animal has anterior poliomyelitis in consequence, the identity would be indicated.

Dr. Edward D. Fisher, New York: That would, of course, be a very essential point if we could get it done. It depends more or less on the pathologic findings. As stated, the report of the case from the pathologic findings would seem to put it outside of the possibility of being poliomyelitis. No micro-organisms were found. The final test would be as mentioned by Dr. Swift.

MORBIDITY REPORTS AND STATISTICS *

A DISCUSSION OF THE PROVISIONS OF THE MODEL STATE LAW FOR THE REPORT OF CONTROLLABLE DISEASES

JOHN W. TRASK, M.D.
Assistant Surgeon-General, United States Public Health Service
WASHINGTON, D. C.

EVOLUTION OF HEALTH DEPARTMENTS

While in this country city boards of health in some instances date back more than a century, and state boards of health have been in existence, some for as long as fifty or sixty years, there has been during the last ten or twenty years a marked growth in their activitives. Health departments are going through a process of evolution, in which they are seeking to adjust themselves to modern thought and recently acquired knowledge. They are in one of the crucial formative periods.

Realizing that they are destined to occupy a broad field, health departments have taken on themselves or had given to them one activity after another, some intimately related to the public health, others in which this relation is more remote. In this taking on of new activities, there has appeared to be a tendency in many instances to forget or ignore the central idea for which they have been founded and about which they must evolve, the control and prevention of disease. There has been a tendency for health departments to take unto themselves the control of all things relating directly or indirectly to the public health and many things relating more especially to social betterment. This course offers special difficulties, as well-nigh all things the community does, practically all its activities, are related more or less closely to its health. There is hardly a department of city or state government which in its activities is not associated at least remotely with the general health.

---

* Read before the Section on Preventive Medicine and Public Health at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

CENTRAL IDEA OF HEALTH DEPARTMENTS

The work which must remain the central idea of the health department is the control of disease.

The control of disease depends on knowledge of its prevalence and the conditions under which it occurs. It has repeatedly been possible to eradicate yellow fever by acquiring exact information of the occurrence of each case. It will be just as necessary to secure similar information of the ocurrence of cases, to eradicate or to control effectively any of the equally dangerous, but more common, preventable diseases. It will probably be found as easy to eradicate typhoid fever or tuberculosis from a community as it is to eradicate yellow fever. In the future, public opinion will probably make it the duty of health departments to eradicate these diseases or at least to maintain an effective control over them. When this time comes health departments will need to be larger than at present and have increased appropriations. There is hardly a state or city health department in the continental United States, the total appropriations of which might not be economically and advantageously expended in the control of any single one of the commoner communicable diseases, such as scarlet fever, typhoid fever, or tuberculosis. One of the first requirements of the future health department will be exact information of the occurrence of each and every recognized case of the diseases it is attempting to prevent.

The need of having this information of the prevalence and geographic distribution of diseases has been realized by physicians in the United States for many years, and the subject has repeatedly come before the American Medical Association in one form or another. At the meeting in 1855 the following resolution offered by Dr. J. W. Thomson was adopted:

> Whereas, few subjects of greater interest and importance could be presented to the consideration of the American Medical Association, now representing most of the States and Territories of the Union, than the attainment of a correct medical topography of each, with a history of its prevailing diseases, and most successful treatment of the same; therefore be it
>
> *Resolved*, That with this view and conviction, this Association appoint a special committee for each State and Territory represented, . . . whose duty it shall be to report on its medical topography, epidemic diseases, and the most successful treatment thereof, and that the same shall continue to hold their office for three years. . . .

At this meeting Dr. J. G. Orton introduced a resolution supplementing the preceding. The resolution, which appears not to have been adopted, was in part as follows:

> *Resolved*, That each county medical society, or (in parts of the country where such has not been established), any duly organized medical association, be requested to amend its constitution by attaching therunto the following article:
>
> "It shall be the duty of each member of this society to keep a faithful record of the diseases which may fall under his observation during each month, according to the classification adopted by this convention in May, 1847, stating the age and sex, occupation and nativity of the patient, the average duration of the disease, and finally, their recovery or death, and to report the same in writing to the secretary, on or before the first day of February of each year, who shall transmit a digest thereof to the State Medical Society and also to the appropriate committee appointed by the American Medical Association for its reception."
>
> *Resolved*, That each incorporated hospital, infirmary and asylum be invited to furnish a copy of their annual reports for the use of the committee of their respective states.
>
> *Resolved*, That the state committees appointed by this Association to report on the prevailing diseases of their respective localities, shall receive and arrange a digest of the reports transmitted to them by the secretaries of the various county societies, and report the same at the annual meeting of this association.

In 1883 Michigan passed a law requiring householders, hotel keepers, keepers of boarding-houses, or tenants, to report immediately to the health officer or board of health all cases of "small-pox, cholera, diphtheria, scarlet fever, or any other disease dangerous to the public health."

The notice was to state the name of the patient, the name of the disease, and the name of the householder or hotel keeper giving the information; also the address where the patient was to be found. Physicians were similarly required to report cases and when the physician reported a case the householder or hotel keeper was not required to do so.

The Michigan law seems to be the first one looking toward the comprehensive collection of information with regard to the prevalence of disease, and for a number of years the work was carried on with intelligence and perseverance under the able supervision of Dr. Henry B. Baker, then secretary of the state board of health.

IMPORTANCE OF MORBIDITY REPORTS

The question of morbidity reports is one of the most difficult problems to be solved by the state authorities. A number of states have been endeavoring earnestly to solve the problem within their respective jurisdictions. Considerable progress has been made in several instances. In 1912 the State of Virginia had 31 cases of diphtheria reported for each death registered, the District of Columbia had 26 cases for each death, Rochester, N. Y., had 31, and Salt Lake City had 53. In the same year Virginia had over 16 cases of typhoid fever reported for each death, Hartford, Conn., had 19 cases, Denver, 16 cases, and Worcester, Mass., 14 cases. With morbidity reports of this degree of completeness the respective health departments have definite information of the prevalence of these diseases and the conditions under which cases are occurring. They possess information which makes them masters of the situation at all times.

The administration of health matters comes within the jurisdiction of the several state authorities. It belongs to the police powers retained by the states, and not delegated to the Federal Government. This makes in the continental United States forty-eight sanitary authorities, and makes it possible to have forty-eight different laws, each with different requirements, for every phase of public-health administration. While this is possible it is by no means necessary nor is it for the common good. The identity of needs and purposes should and will cause a mutual exchange of ideas and a general selection of the best for common adoption. Thus, the states will develop a closer union in sanitary administration.

For this purpose some form of public-health congress or council with representatives from the several states is necessary. With this idea in mind the Congress of the United States in 1902 provided for conferences of the state and territorial health authorities with the Federal Public-Health Service. These conferences have been held annually and at the one held in Minneapolis in June, 1913, there was adopted a standard model law for morbidity reports. The law was drafted in tentative form by a committee appointed two years before and was the subject of full discussion and amendment by the conference.

A discussion of the provisions of this law cannot be other than of interest to all in any way connected with public-health administration.

MODEL HEALTH LAW REQUIREMENTS

Section 1 of the law makes it the duty of the state department of health to keep currently informed of the occurrence, geographic distribution and prevalence of the preventable disease throughout the state, and for this purpose establishes in the state department of health a bureau of sanitary reports.

The purpose of this section will be apparent to all familiar with the control of disease. The only rational reason for the existence of a state department of health is that it may control the controllable diseases throughout the state either directly or through the local health authorities. In either instance disease cannot be controlled in the absence of dependable current information of the occurrence and geographic distribution of the cases.

No one would think of attempting to control cholera, plague, or yellow fever without providing for some means of getting early information of each case. This is one of the things to be considered and for which provision must be made in every sanitary campaign against these diseases, but it is just as true in the control of any other disease. Whenever a health department sincerely attempts to lessen the prevalence of tuberculosis in its jurisdiction it will need to know of, and will require the notification of all cases of the disease. Whatever control the health department can exercise over such diseases as diphtheria, scarlet fever, measles, epidemic cerebrospinal meningitis, can be exercised only through a knowledge of the occurrence of cases. Communities in a measure control the incidence of typhoid fever by the installation of pure water supplies and in some cases by requiring the pasteurization of milk, but these things are but factors. Pure water and pasteurized milk will but lessen the incidence of typhoid fever, and a knowledge of the occurrence of cases is still necessary not only to control the other factors which spread the disease, but to know when the measures taken are inefficient or need adjustment. Given a city with an absolutely pure water-supply and with the lowest of typhoid-rates, it would still be necessary that any cases that did occur should be immediately reported because each case would show a break in the community's sanitary wall which needed attention.

Vaccination and re-vaccination will protect a community against small pox. Nevertheless, that community would be foolhardy and unmindful of its welfare which did not require the notification of cases of this disease, for occasional cases may occur even in the best vaccinated communities. What is true of this disease is true of every other. Control is impossible without a knowledge of when and where, and under what conditions cases are occurring.

Section 2 of the law names the diseases of which cases shall be notified. The list is divided into four groups: (1) infectious diseases, (2) occupational diseases and injuries, (3) venereal diseases, and (4) diseases of unknown origin. The first three groups include most of the diseases which occur in this country and which, with our present knowledge, may be controlled. They consist of the diseases for the control of which presumably health departments have been established.

Group 1 includes the infectious diseases, among which will be found those which have been reportable in many states for some time.

Group 2 includes occupational diseases and injuries. Occupational diseases constitute a class which in this country have but recently received anything like the amount of attention they deserve. Practically all occupational diseases are preventable and are subject to control. During the last fifty years there has come about a marked change in industrial conditions, not only in the United States, but in other countries as well. There have grown up immense manufacturing plants, large shops employing thousands of hands. There have been developed new and complex labor-saving machines, new processes have been evolved, new fabrics and materials are now being used and with this evolution of industrial methods and conditions there have arisen new occupational diseases and an increasing incidence of older ones. In an industrial community approximately one-third of the population is engaged in shops and factories, or similar places of labor, so that industrial hygiene and the prevention of occupational diseases has grown apace with our industrial development until industrial hygiene now constitutes an important factor in national and community hygiene.

Since 1911 fourteen states have enacted laws requiring the report of certain, or all occupational diseases. These laws for the most part have been impossible of enforcement, at least they have been in most instances unsatisfactory. Nevertheless, they show a recognition of the importance of knowing where cases of occupational diseases are developing. Every case of occupational disease shows the existence of conditions capable of producing disease, conditions which should be removed so that they will not produce the diseases in others. The first step in the control of occupational disease, as in the control of other diseases, is to secure a knowledge of where and under what conditions cases are occurring.

Group 3, the venereal diseases, constitute a group which offer great difficulties in their control. It will be a long time before it will be possible to have all cases of these diseases notified. They have been made notifiable in a number of states and properly so, for there are few diseases which cause more injury to the community than do these. Every case represents a focus of infection from which the disease may be and usually is spread to others, and it is only proper that each and every case be so controlled that it shall be impossible for the infection to be spread.

The fourth group of diseases includes pellagra and cancer, diseases of unknown origin, and the purpose of the notification of the existence of these is, not that the disease may be controlled, but because of the possibility that a knowledge of the relative prevalence and geographic distribution of these diseases and the conditions under which cases occur may be of assistance in the search for their origin.

Section 3 of the law requires physicians to report each and every case, or suspected case, of any of the notifiable diseases in his practice to the local health officer, this report to be made either by mail or by special messenger. The report, which is to be in writing, is to show the date; the name of the disease or suspected disease; the name, age, sex, color, occupation, address, and school attended or place of employment of the patient; number of adults or children in the household; the source or probable source of infection or the origin or probable origin of the disease, and the name and address of the reporting physician. If the disease is, or is suspected to be small-pox, the report in addition is to show whether the disease is of the mild or the virulent type, and whether the patient has ever been successfully vaccinated. If the patient has been successfully vaccinated, the number of times and the dates, or approximate dates of such vaccination are to be given. If the disease is, or is suspected to be, cholera, diphtheria, plague, scarlet fever, small-pox, or yellow fever, the physician is, in addition to the written report, to report the case immediately to the local health officer in the most expeditious manner available. If the disease is, or is suspected to be, typhoid fever, scarlet fever, diphtheria, or septic sore throat the report is also to show whether the patient has been, or whether any member of the household in which the patient resides, is engaged or employed in the handling of milk for sale or preliminary to sale.

The reason for the various data required in the report is readily apparent. The dating of the report is necessary. The giving of the name, age, sex, color, occupation and address are necessary for identification and for statistical purposes. The school attended or place of employment gives early information to the health department as to where the disease has been contracted and also where others have been exposed and contacts will be found. The number of adults and children in the household indicates the nature of the precautions that will need to be taken to prevent the spread of the disease, while the stating of the source or probable source of the infection or origin of the disease by the physician would often give useful information to the health department. The requirement for the notification of cases of disease should always provide for the report of suspected cases, and there should be connected with every health department an expert diagnostician of the controllable or notifiable diseases.

A health department that has not on its staff such a diagnostician is not in a position to control the notifiable diseases. Much as one might wish to believe that physicians never err in diagnosis, in practical health administration one is compelled to face the fact that many physicians see few of these diseases and their experience is therefore limited. The most, therefore, that a physician should be asked to record on a notification report is that the disease is, or is suspected to be of a certain kind. The health department should verify the diagnosis. The provision requiring that in cases, or suspected cases of cholera, diphtheria, plague, scarlet fever, small-pox, or yellow fever, the physician shall, in addition to the written report, give immediate notice to the health department in the most expeditious manner available, enables the use of the telephone or at times of the telegraph, or in the absence of these means a special messenger might be used. The need for the expeditious notification of these diseases does not require explanation.

The requirement that in cases or suspected cases of typhoid fever, scarlet fever, diphtheria, or septic sore throat the reports shall also show whether the patient has been, or any member of the household in which the patient resides is engaged in the handling of milk, is made because of the well-known fact that these diseases are frequently spread by milk, and the control of the disease and the protection of the community depends on the protection of milk-supplies from persons infected with these diseases.

The requirements of Section 4 with regard to the notification of cases is made to apply to patients in hospitals or other public or private institutions and to physicians attending these patients.

Section 5 of the model law provides that whenever a person is known to be, or is suspected to be affected with a notifiable disease and no physician is in attendance, then an immediate report of the case shall be made to the local health officer by the person in charge of the patient. Teachers, or other persons employed in public or private schools including Sunday schools are required by the law to report immediately to the local health officer each and every known or suspected case of a notifiable disease in persons attending or employed in their respective schools.

The blanks to be used in making the written reports are to be supplied by the state department of health through the local health officers and are to conform to a standard form adopted by the conference of state health authorities. These blanks are printed on a post-card. This is believed to be the most convenient form of report for the physician as it does not require an envelope and needs no addition of postage.

Section 8 requires local health officers within seven days after the receipt by them of reports of cases of the notifiable diseases to forward by mail to the state department of health the original written reports made by physicians, after having first transcribed the information given in the respective reports in a book or other form of record for the permanent files of the local health office. On each report thus forwarded the local health officer is to state whether the case to which the report pertains was visited or the case otherwise investigated by a representative of the local health office, and whether measures were taken to prevent the spread of the disease or the occurrence of additional cases. If the patient was not visited or otherwise investigated by a representative of the local health office it is evident that the diagnosis might have been incorrect, and if no measures were taken to prevent the spread of the disease or the occurrence of additional cases the question might well be asked, What was the use of the report?

Section 10 of the law provides that whenever there occurs within the jurisdiction of a local health officer an epidemic of a notifiable disease the local health officer shall, within thirty days after the epidemic shall have subsided, make a report to the state department of health of the number of cases occurring in the epidemic, the number of cases terminating fatally, the origin of the epidemic, and the means by which the disease was spread, except that, whenever the state department of health has found it necessary to take charge of the control and suppression of an epidemic, the local health officer having jurisdiction need not make this report. This provision will give a connected account of the outbreaks of controllable diseases occurring within a state. They will also show what measures were taken locally to control the outbreaks and whether the measures were efficient.

Section 11 provides that no person shall be appointed to the position of local health officer until after his qualifications have been approved by the state department of health. If the control of disease in local jurisdictions and the protection of the public health is to be in charge of local health officers it is absolutely essential that there be some means of having their competency and eligibility passed on. Also, if the state department of health is to be made responsible in any way for health conditions within the state, it must have some control over the local health authorities. If responsibility for the control of disease within a state is not placed on the state health department, one might well ask, what is the purpose of the state health department?

Section 12 of the law provides that where there are no local health officers, and in localities where although local health officers have been appointed, adequate provision has not, in the opinion of the state department of health, been made for the proper notification, investigation, and control of the notifiable diseases, the state health department shall appoint properly qualified sanitary officers to act as local health officers and to prevent the spread of disease in and from such localities.

Section 13 makes it a misdemeanor for a physician or other person wilfully to fail to comply with the provisions of the act. It seems perfectly proper to assume that no physician who works against the community's interest and places obstacles in the way of the control of disease and public health administration by intentional failure to report to the health department the cases of notifiable diseases among his patients should be allowed by a state to practice medicine.

Section 14 of the law provides that no license to practice medicine shall be issued to any person until after the applicant shall have filed with the state licensing board a statement signed and sworn to before a notary or other officer qualified to administer oaths, that he has familiarized himself with the requirements of the law. A copy of this sworn statement is to be placed on file with the state department of health. This is simply to guarantee that every licensed practitioner will be familiar with the law with regard to the notification of disease.

The provisions of the model law slightly amended have already been adopted by the State of Kansas through regulations promulgated Dec. 13, 1913. As opportunity affords other states will undoubtedly take similar action.

ABSTRACT OF DISCUSSION

Dr. A. T. McCormack, Bowling Green, Ky.: After listening to Dr. Trask's paper, it seems easy to understand why resolutions passed in 1842 and 1855 calling for morbidity statistics had so little effect, and I fear that future essayists will report the recommendation of such bills as this as quite as ineffectual as these resolutions passed fifty years ago. Such a health organization as Dr. Trask has described would be delightful, but I venture to say that when it becomes possible for any health organization to have enough inspectors to confirm every diagnosis of a preventable disease reported to it by the practicing physicians of the jurisdiction, the millennium will already have arrived. On what meat would Dr. Trask have us feed our sanitary inspectors to make them so much more competent than the average reputable physician? Inspectors are selected from the medical profession; they are educated and trained alike, and a commission and a salary add but little to the stature or qualifications of the average man. Morbidity statistics are of tremendous importance. For them to be of real value accurate diagnoses are essential, but, instead of having an inspector to confirm the work of each physician, would it not be better for us to demand that those physicians who are unable to make accurate diagnoses should be excluded from the practice of medicine? In fact, is this not the purpose of every medical registration law in the land? The time has come when we know something definite about preventable disease. In almost every jurisdiction we are getting actual results, and instead of further centralization of our health organization with its result in dry statistics and ultrascientific and impracticable atmosphere, it has seemed to me that the family physicians, scattered all over the country, compose the great bulk of the sanitary force that are to save this country from the thralldom of preventable diseases. I do not believe for one moment that such an army of inspectors as is contemplated by Dr. Trask is necessary or that it will ever be created in this country except as we develop such a practical conception of state medicine that it will transform the family physician into the community physician and thus enroll the whole medical profession as practitioners, first, for the prevention of all the diseases possible, and, secondly, for the treatment of the non-preventable diseases. A health organization, to be successful, must have the confidence and support of the medical profession; and any statistics made by that profession, until the individuals composing it are competent to make a diagnosis, are of no real value.

Dr. Tom Williams, Washington, D. C.: Dr. Trask spoke of occupational diseases, and that is a matter which must be taken into serious consideration in the immediate future of public-health matters; because workmen's compensation acts are coming into force all over the country. Let us herein be forewarned by the measures of Germany, France, in part, and England with regard to the dangers of the workmen's compensation acts. Of course, we all admit the need of workmen's compensation acts, and the importance of protecting the workingman against want on account of accidents in his occupation; but what has actually happened in the demonstration is this, that in Germany the present upkeep of the fund of indemnity for workmen's compensation exceeds that for the German army, per annum, which is colossal.

Of those cases, however, 75 per cent. belong to a category which is very little understood by most practitioners, and which in consequence very few men know how to manage, but which can be met quite simply. I refer to neurotic disturbances, neurasthenias, neuroticisms. Most of these cases are amenable to proper treatment, and all are preventable. Although some of the patients are actually simulators, who pretend disease for the sake of indemnity, many of them are genuinely disturbed "neurotically" by the idea that they are no longer fit for work, as a consequence of some accident. These cases can be well dealt with by modern methods of psychopathology; and it is just as well that public officials dealing with the administration and the passing of acts for workmen's compensation should be aware of this fact so as to be ready to anticipate and prevent what has occurred in Germany. We have had to take hold of the scandal of indemnification for railway accidents so that now we no longer expend public money and money of corporations in large amounts for pretended injuries.

Dr. S. L. Jepson, Wheeling, W. Va.: The fact is, whatever local laws or state laws we may have to-day on the subject of reporting disease, nearly all these laws fail of enforcement; and I do not see how they can be enforced. We have in our state law a provision, for instance, for the reporting of births, with a fee of 25 cents each attached. The counties refuse to pay the 25 cents; and, therefore, the doctors refuse to report the births. They fail to report cases of infectious disease promptly, except in the cities where there is a vigorous health department, or in case of small-pox. How to induce our physicians to make these early reports is the proposition of greatest importance. Perhaps Dr. Trask can give us a little further light on that subject.

Dr. Martin Friedrich, Cleveland: There is a provision in this model health code that, within seven days after notification of a communicable disease, the local health officer must report it to the state board of health. There is also an item in which he has to state what he has done; for, as Dr. Trask added, "if nothing is done, what is the use to report diseases?" Very good; but if, after the disease or the epidemic is reported to the state board of health, the state board of health does nothing, what is the use to report to it? In towns and villages around Cleveland, where not infrequently little epidemics of scarlet fever, diphtheria, etc., occur, the local authorities frequently do little or nothing to confine the disease, and as the people come almost every day to Cleveland to sell their produce, for instance, milk, you can readily see there is danger for us. There ought to be an item in the code which would make it mandatory for the state board of health to act when the local authorities do not.

Dr. I. D. Rawlings, Chicago: Not one item is presented in this model bill that would not be feasible in Chicago. We are absolutely prepared to carry out all the provisions; and what is applicable in Chicago should be in many of the other cities of the states and even in the rural districts. We have found in Chicago that some of our physicians will not do their full duty unless compelled. We are now prosecuting some of these for failure to comply with our city ordinances requiring the reporting of contagious diseases. In diphtheria we insist on a positive diagnosis. If the physician does not take a diagnostic culture, we insist on the health officer doing so, and, if necessary, two diagnostic cultures are taken. We require placarding in Chicago for scarlet fever and measles cases; but we do not for German measles. Some of our physicians, as a subterfuge, would report a good many scarlet fever and measles cases, as German measles in order to avoid placards. To circumvent that, we wrote into our instructions the following:

"As mild cases of scarlet fever or measles are not infrequently mistaken for German measles, resulting in a localized epidemic of these diseases, and as a few physicians report the more serious eruptive contagious diseases as German measles in order to avoid placards and quarantine, the health officer will inspect all cases reported by physicians as German measles. If after examination the health officer regards the case as a contagious disease requiring placards instead of a case of German measles, he will telephone a report to the division chief. The case will be assigned promptly to a supervising health officer, who shall make one or more attempts to reach the attending physician by telephone, and if successful, ask him to see the patient with him. In any event the supervising health officer must promptly see the case. If a disease is found requiring placards, the supervising health officer must quarantine and make report in usual form." We inspect every case of unvaccinated chicken-pox to confirm the diagnosis of the attending physician. I believe this bill is absolutely feasible—in our city at least.

Dr. Charles J. Hastings, Toronto, Ontario: I quite agree with Dr. Rawlings that a well-organized department of health in any municipality ought to be able to carry out every clause of the act as presented. With regard to the report of cases I think it is frequently our fault in not keeping in close enough touch with the general practitioner. In my judgment, the most valuable asset that any department of public health has is the entire cooperation of the profession in the municipality for which the health officer is responsible. It is not uncommon for physicians in Toronto to call up the department of health, if there is any doubt with regard to a case of communicable disease, and ask to have one of our diagnosticians call and see the case. By doing so we relieve the family physician of the responsibility of having the family quarantined. The honest physician is frequently placed in an unfavorable position with his patients by an unscrupulous doctor who has attended a case next door and did not report it. I am thankful to say that we rarely have cases of this kind, but when we do we prosecute them forthwith. It is our duty to do so both to the public and to the honorable and conscientious physician who promptly reports his cases. I presume all departments of health require two negative swabs for release of diphtheria cases. I think that departments of health should require that some physician from their laboratory take the releasing swab. This also relieves the family physician from being accused by their patient for keeping them quarantined unnecessarily long and at the same time prevents the faking physician from sending in a bogus culture. I am sorry that Dr. Trask passed over the matter of venereal diseases so lightly as he did. I think there is nothing that will bring down the anathemas of future generations on the activities of departments of health more than our absolute disregard for the control of venereal diseases, a class that is probably of more national importance than all other communicable diseases combined; and yet we are in a sense practically disregarding them, afraid to touch them, on account of — what? Of the conditions under which they are contracted. Departments of health have nothing to do with the conditions under which they are contracted. If we are going to handle these diseases efficiently we must handle them as we would small-pox, diphtheria, or any other communicable disease, we must divorce them from the social aspect entirely. We have nothing to do with that; we have simply to deal with the dangers to humanity of these diseases. If we go on, with our heads buried in the sand, as we have been doing in the past, there is going to be great reflection on our deficient administration.

Dr. J. W. Trask, Washington, D. C.: I am grateful to Dr. McCormack for bringing out the phase of the subject that he did; because others, probably, look at it from the same point of view. Our country has a vast area and a varying density of population. To one whose experience has been largely in a semirural territory, in which, because of its scattered population, progress in securing satisfactory morbidity reports has naturally been delayed, the model law may seem utopian. It is entirely practical as has been shown by those who have just stated that they were already carrying out most of its provisions and that their communities were ready to carry out the remainder. The law is in operation in Kansas in the form of regulations adopted in December, 1913. I prefer not to think of morbidity reports as statistics. When we get sufficiently complete reports, their compilation will furnish us with morbidity statistics; but the main object of the notification of disease is its control in practical everyday health administration. One of the hopeful things is the great interest that is being shown, not only by the people in general, but also by the medical profession, in advancing public-health activities. Every physician who believes in greater public-health activities and in the control of disease, must necessarily abide by his state laws or regulations for the control of disease; he reports his cases and, in addition, shows an interest in the efficient control of disease in his community. Dr. Friedrich's point is fundamental. If nothing is done as a result of the report of a case of notifiable disease, why the report? That can be considered a proper question whether it concerns the primary report to the local health department or the secondary report of the local health department to the state health department. If nothing is done the report has little value. The statistical value of it is not sufficient if actual preventive measures are neglected. I purposely omitted Dr. Hastings' point—venereal diseases—not because I did not believe that they constitute one of the major public-health questions. When we get confidence in the importance of our work and really believe in its value; when we divorce from the health department the licensing of plumbers and the control of plumbing, we will occupy our time with such big, important questions as the control of venereal diseases.

General Practice as a Specialty.—General practice has, in a certain sense, become a specialty. It is true that its ranks contain a larger number than any other branch of the profession, but the large increase of the number of whole-time appointments and of specialists of every conceivable variety in the last few years and months raises a doubt as to how long this numerical preponderance will obtain. But we are at least assured that there is no danger of the extinction of the general practitioner. The intimate personal relation between the individual patient and his doctor is an essential factor which no changed conditions can completely eliminate. It is on the general practitioner that the eyes of the public and the profession are now turned, and we are confident that the trust will be completely justified.—*British Medical Journal.*

UNFAVORABLE COMPLICATIONS FOLLOWING AN INTRADURAL INJECTION OF NEOSALVARSAN

ALFRED GORDON, M.D.
PHILADELPHIA

In the treatment of syphilitic affections of the nervous system three principal methods are at our disposal, namely, intravenous injection of the drug, intradural injection of autosalvarsanized serum (Swift-Ellis), and intradural injection of neosalvarsan (Ravaut). According to the majority of competent observers the first procedure has proved to be of little avail, especially in cases of late manifestations of syphilis of the nervous system, in tabes for example. The reason lies partly in the impermeability of the meninges for the drug. The other two methods aim at a direct contact of the drug with the cerebrospinal axis. Salvarsan, in the light of our present experience, must be abandoned for this purpose by virtue of its caustic action. As this caustic feature is eliminated in neosalvarsan, the latter is the one to be applied.

After the unsuccessful attempts of Wechselman in 1912 and Marinesco in 1913, also of Levaditi and Marie in the same year, Ravaut[1] reported very satisfactory results from direct injections of neosalvarsan into the spinal canal. U. J. Wile, in this country, followed strictly the special technic devised by Ravaut, and in a recent contribution[2] describes the results of his experience with fifteen patients distributed as follows: Tabes seven; paresis five; cerebrospinal syphilis three. Out of this group seven showed marked improvement; the patient with cerebrospinal syphilis gave better results than the cases of tabes and paresis; the tabetic patients without bladder and rectum disorders have been especially benefited by the treatment. In view of this experience Wile expresses confidence in the method of intradural injections of neosalvarsan as devised by Ravaut. As a careful observer he points out two interesting features in this treatment, however, against which he cautions the therapeutist. First, he advises the use of only very small doses of the drug, and secondly, the involvement of the bladder and rectum seem to serve as a contra-indication for the treatment.

My latest experience in the treatment of syphilitic involvement of the nervous system consists chiefly in the use of autosalvarsanized serum. Subject to a later publication in detail, I may say at present that this method has given me far more satisfactory results than any other old or newer methods. Stimulated by the work of Ravaut I attempted to apply his procedure in a case of tabes. In view of Wile's favorable report[2] I feel it a duty to call attention to most undesirable consequences which may follow the use of Ravaut's technic of intradural injection of neosalvarsan.

The patient, a man of 35, presented all the typical symptoms of tabes dorsalis. At the time he came under my observation, pain in the lower extremities, ataxia, incontinence of urine and constipation were the most conspicuous manifestations. Formerly, I was told, he had the usual course of treatment with iodids and mercury. At this time the Wassermann reaction of serum and spinal fluid was positive.

I proposed at once the treatment with autosalvarsanized serum which was promptly accepted. The result from one injection was gratifying. The pain had almost disappeared, the ataxia improved, also the incontinence of urine decreased considerably. Constipation remained unaltered.

For a period of two months the patient felt very comfortable. Soon, however, the bladder disturbance returned. As the Wassermann reaction was at this time positive, the patient finally accepted the offer to have another intraspinal injection which he had repeatedly refused during the past two months. With the patient's consent I had recourse this time to a direct intradural injection of neosalvarsan instead of the autosalvarsanized serum. Accordingly I had the fluid prepared after Ravaut's technic. The solution used was 6 per cent. of neosalvarsan in distilled water. As each drop of the solution contained 3 mg. of neosalvarsan, only two drops were injected from a specially constructed and very accurately graduated syringe. The lumbar puncture was made with a needle the end of which fitted the graduated syringe. After a small quantity of spinal fluid had flowed out of the cannula and been collected in a tube for diagnostic purposes, the syringe was attached and the fluid allowed to run into it in order to mix with the drug. Then the mixed fluid was pushed gently into the canal. The procedure of mixing was repeated the second time. The patient was then placed in Trendelenburg's position.

One-half hour after the injection the patient commenced to complain of severe pain in the lower limbs, which in subsequent days became more and more pronounced. Vomiting appeared on the same day and kept up for six consecutive days. Retention of urine took the place of the former incontinence. Incontinence of feces made its appearance. All these symptoms continued without relief. On the fifth day small erythematous patches appeared on the glans penis, on the scrotum and on the sacrum. They gradually became larger and finally distinctly gangrenous.

Two weeks after the injection the patient presented the following condition: He was unable to stand or walk; he suffered agonizing pain in the lower limbs so that sleep was impossible; retention of urine and incontinence of feces were exceedingly disturbing; the gangrene of the above mentioned areas was becoming more and more profound; the temperature reached 102 and 103 F.; he vomited daily, lost his appetite and was losing weight. Gradually the condition grew more and more alarming and finally he expired.

This case seems to militate against the direct intradural use of neosalvarsan notwithstanding the favorable reports of Ravaut and Wile. It is possible that Wile's suggestion with regard to the sphincter complications as being a contra-indication for this treatment has its *raison d'être* here. Nevertheless the damage done by this procedure even in one case sufficiently deserves the attention of those who contemplate the use of this method. Perhaps further investigations on animals and a more carefully elaborated technic will enable us to view the method in a more favorable light. In a recent contribution Corbus[3] reports an experience similar to mine.

APPLICATION OF RADIUM IN THE BLADDER FOR CARCINOMA

WITH REPORT OF TWO CASES

F. J. SCHOENENBERGER, M.D.
Adjunct Professor of Genito-Urinary Surgery, Fordham University, School of Medicine; Assistant Visiting Genito-Urinary Surgeon, City Hospital

AND

S. WILLIAM SCHAPIRA, M.D.
Adjunct Professor of Genito-Urinary Surgery, Fordham University, School of Medicine; Visiting Surgeon (Genito-Urinary), Sydenham Hospital; Assistant Genito-Urinary Surgeon, City Hospital

NEW YORK

To review at this time the various surgical conditions to which radium has been applied would be without gain, in view of the very recent development of our knowledge and use of this new element, which is being brought to our attention almost daily. We believe, however, that in reporting our cases, we are presenting for the first time a complete history of the action of radium as applied in the bladder in cases of carcinoma, accompanied as they are by cystoscopic examinations before and after application, microscopic examinations of the tumors and end-results.

After a careful review of the literature we find very few cases in which radium was applied in the bladder in cases of carcinoma. One case is reported by Cauhape in which he applied radium to the bladder for carcinoma of the prostate with cure in nine months. These applications were made with radium attached to a catheter and introduced into the bladder per urethram. Twenty-five mg. of radium were used and the applications made every three days, each application lasting two hours. Wickham and Degrais in their latest work do not mention the use of radium in the bladder. The Radium Institute of London in 1912 reported two patients treated with results not noted, and also two patients for prophylactic treatment, reported as improving. The Royal Infirmary of Edinburgh reported no bladder cases in 1912. The foregoing constitutes about all the information that we could obtain, demonstrating that in only one authenticated case, (that of Cauhape) is there any definite report as to the nature of the tumor, amount of radium used, length of application and end-result.

The two cases that have come under our observation are as follows:

Case 1.—M. J. T., aged 34, consulted us, Sept. 23, 1913. Family history shows that father probably died of carcinoma of stomach. Patient gives history of hematuria for about five years, occurring at intervals of about three months until recently, when attacks became very much more frequent. There had been no pain until shortly before the patient's visit to us. At this time the patient complained of hematuria and sharp pains in right inguinal region radiating to pelvis. Examination showed patient to be in fair physical condition. There was a left bubonocele. In right inguinal region a mass about the size of an orange could be felt. This mass was hard, immovable and extended down into the pelvis. There was edema of the right thigh. Cystoscopy showed a tumor, about the size of an English walnut, situated in the trigon, midway between its center and the opening of the left ureter in the bladder. The tumor was friable. The right ureter was obstructed, but showed urine escaping. Examination of metastatic growth, microscopically, showed the tumor to be carcinoma.

Oct. 7, 1913, a suprapubic cystotomy was done. A tube containing 15 mg. of radium was attached to the lower end of a Freyer tube and introduced into the bladder in direct contact with the tumor and allowed to remain in place for twelve hours. No discomfort was complained of by the patient at any time during the application. The same tube of radium after removal from the bladder was buried in an incision over the metastatic growth and allowed to remain in place for twelve hours. The bladder wound was completely closed on the eleventh day after the operation. Recovery from the operation was uneventful except for unaccountable attacks of pyrexia, beginning forty-eight hours after operation, lasting for three days and recurring again at the end of a week. Three such attacks occurred. Cystoscopy, December 8, two months after operation, showed that the tumor of the bladder had entirely disappeared. The mucous membrane of the bladder appeared normal. Both ureteral openings were obstructed. The metastatic tumor in the groin was about the size of an English walnut. The patient died six months after operation from general asthenia and hydronephrosis due to obstruction of ureters by metastatic growths in the pelvis.

Case 2.—B. K., aged 67, was first seen by us Jan. 4, 1914. Family history was negative. Patient complained of frequency of urination day and night for about eighteen months. During the last three months he has had pain in the region of the bladder and perineum accompanied by frequency and hematuria. He has lost about 40 pounds in the last three months. His appearance is cachectic. He was discharged from the German Hospital, after ten days' observation, as having an inoperable case. Residual urine was 12 ounces, bloody and ammoniacal. Blood-pressure from 190 to 170. Blood examination: White cells, 18,000; polynuclears, 83 per cent.; lymphocytes 11 per cent.; eosinophils, 1 per cent. Rectal examination shows large hard prostatic tumor. Cystoscopy shows large bleeding tumor slightly to left of left ureteral opening; smaller tumor near the right ureteral opening; also large eroded and bleeding tumor at site of prostate. The entire mucous membrane of the bladder appears infiltrated. Diagnosis: Carcinoma of prostate and bladder.

Patient entered hospital January 6, and a permanent catheter was introduced for drainage and irrigation preparatory to operation, suprapubic cystotomy, which was performed January 8. A tumor the size of an egg at the site of the left ureteral opening was removed. A tumor on the right side, somewhat smaller, was also removed. A V-shaped section was removed from the prostatic tumor. The prostatic growth is considered by us to have been the primary focus in this case. The section taken from the prostate also provided better drainage through the urethra. The same procedure in the use of the radium was pursued as in Case 1. The bladder was closed in three weeks. The same unaccountable pyrexia occurred as in Case 1. Patient was discharged from the hospital February 5, about four weeks after operation. At this time the patient was passing clear urine four times a day and every three hours at night at our direction to prevent distention of bladder and reopening of suprapubic wound. Patient gained 26 pounds in weight in two months. Cystoscopy, April 22, showed bladder mucosa apparently normal, the surfaces from which tumors had been removed appearing as small pale, depressed areas. All of the surfaces appeared to be covered by normal mucous membrane. Rectal examination showed prostate greatly diminished in size and of normal consistency. Residual urine, 3 ounces.

The pathologic report of Case 1 is from the laboratory of St. Francis Hospital; the pathologic report of Case 2, is from the laboratory of the City Hospital.

CONCLUSIONS

1. We may without danger, even without discomfort to the patient, place in the bladder as much as 15 mg. of radium and allow it to remain as long as twelve hours.

2. We believe that we have shown that radium has the power to remove a tumor of the bladder (carcinoma) and of the prostate within a period of two

months. It has also been demonstrated in Case 1 that radium has had a very decided effect in reducing the size of a metastatic growth associated with carcinoma of the bladder.

3. No difference seems to have been evident in the result whether or not part of the tumor was removed. In Case 1 no part of the tumor was removed, while in Case 2 a considerable portion of the tumors was excised.

4. We are of the opinion that the peculiar pyrexia associated in both cases was due to an absorption following the destructive influence of the radium on the tumors. A thorough investigation did not disclose any other cause.

We wish to take this opportunity of thanking Dr. Wolf Freudenthal for the use of the radium applied in these cases.

A CASE OF BACILLUS DYSENTERIAE SEPTICEMIA

W. T. DE SAUTELLE, M.D., KNOXVILLE, TENN.

In the literature at my disposal, instances of isolation of the *Bacillus dysenteriae* from the blood during life seem to be very few in number. Darling and Bates (*Jour. Med. Sc.*, 1912, cxliii, 36), report a fatal case from which they recovered from the circulating blood the *B. dysenteriae* of the Shiga type. All of the references at hand either make no mention of the *B. dysenteriae* entering the general circulation or state positively that it does not do so. It seemed to be of interest therefore to report the following case which was seen in consultation with Dr. C. G. Hutson of this city.

The patient was a 3-weeks-old breast-fed infant which had been in perfect health before the onset of the disease. For a day or two the baby refused to nurse, became irritable, restless and did not sleep. The child was stupid and listless, whined at times and objected to the slightest touch. Physical examination revealed no abnormalities or pathologic processes in any of the organs. The temperature was 103 and pulse 180. At this time there was no diarrhea. In consideration of the fact that the grandmother of the infant was suffering in the same house with typhoid fever, a blood-culture was made. As we were unable to enter a vein, the blood was taken from the great toe and placed in bouillon from which the *B. dysenteriae* was obtained in pure culture. Although the baby's toe was carefully cleansed and the blood dropped directly into the bouillon, we did not give much significance to the result of the culture.

The baby continued to have a fever varying from 101 to 104.5 in spite of antipyretic measures and also developed a watery diarrhea. Five days later the baby suddenly began to have severe convulsions which came on every few minutes and lasted from five to ten minutes. When seen the hands, face and feet were very cyanotic, the pulse thirty to the minute, the breathing of the Cheyne-Stokes type, the pupils dilated and inactive to light, divergent strabismus, the tendon reflexes absent (at the first examination they were normal), and the child comatose. Through a lumbar puncture needle the spinal fluid flowed out quite rapidly, but contained at least one-half blood. The fluid came as bloody at the end of the flow as at the beginning, in fact, the needle was withdrawn and reintroduced at three different places with the same result. After the removal of 3 or 4 c.c. spinal fluid the convulsions ceased for a time, the pulse and respiration improved, and the cyanosis cleared up. The child died several hours later. Post-mortem was refused.

The spinal fluid obtained was carefully placed in bouillon and an organism found which was identical in all respects with the one obtained in the blood-culture.

The organism cultivated from the blood and spinal fluid had the following characteristics: It was a Gram-negative short bacillus, only sluggishly motile, and did not produce indol in five days or coagulate or digest milk. It produced acid in litmus milk and this remained so for three days. In dextrose, levulose, lactose, mannite, galactose, maltose and dextrin bouillon this bacillus produced acid but no gas in twenty-four hours. Saccharose and inulin were unchanged. At the end of three days the mediums remained unchanged.

The organism corresponding to these reactions is the bacillus "Rosen" (from dysentery) and we therefore concluded that this was a case of *Bacillus dysenteriae* septicemia. The finding of the same organism in the bloody cerebrospinal fluid and the blood taken from the child's toe convinced us that the organism had been present in the general circulation from the onset of the illness. Death was no doubt due to the cerebral hemorrhage rather than to the toxemia. Nevertheless this case with the fatal case previously mentioned would lead one to think that the advent of the *B. dysenteriae* into the general circulation means a fatal outcome of such cases. More reports of *Bacillus dysenteriae* septicemia are necessary, to be sure, before drawing such a conclusion.

The source of infection could not be ascertained. The child was breast fed and the parents denied having given it any other food. It may have been given unboiled water, but this they also denied. The sick grandmother handled the infant and even kissed it on the mouth several times. The diagnosis in her case, however, was unquestionably typhoid fever, as a blood-culture done by Dr. A. L. Smith in our laboratory revealed an organism identical in all its reactions to the *Bacillus typhosus*.

HYGROMA OF THE GROIN

PERCY WILLARD ROBERTS, M.D., NEW YORK

The following case of hygroma in the groin is of interest on account of its apparent rarity and also because the method by which healing was finally induced is not commonly in vogue.

Surgical literature contains very little concerning hygroma in the groin. In a carefully prepared paper by Dowd in the *Annals of Surgery* for June, 1913, in which are reported several of his own cases, he goes over the literature of hygroma and refers to the fact that it seldom appears in the groin. A rather painstaking search fails to reveal any reported instances of cystic formations in this region, though, doubtless, cases have been noted, for the abundant supply of lymphatic tissue here would indicate a fertile field for their development.

The patient was a boy of 16 who was sent me with a diagnosis of psoas abscess, to which clinical appearances pointed. There was present at the upper and anterior aspect of the right thigh a large tumor extending from the groin half way to the knee, with the characteristic feel of a tense abscess. On the outer side of the thigh there was a discharging sinus through which a probe could be passed to a point over the head of the femur. Examinations of the hip-joint and spine were, however, negative, as were also roentgenograms of these parts.

Nevertheless, the clinical picture was one of cold abscess. The swelling had enlarged rapidly, having developed in three months without pain or temperature, and there was no history of injury or infection.

The patient was taken to the Post-Graduate Hospital, and incision of the tumor resulted in the evacuation of about a quart of a clear, straw-colored fluid which contained no pathogenic organisms. Exploration revealed a multilocular cavity extending to the ramus of the ischium without definite source of origin, the bone not being involved. There was no connection with the sinus on the outer side of the thigh. The cavity was lined with an extremely delicate membrane, but there was apparently no limiting membrane of a fibrous nature, the resistance of the muscles and fascia acting as a retaining wall.

The cavity was thoroughly scraped and allowed to drain. A few days later a constriction half way toward the ischium closed and the upper end of the cyst rapidly refilled, necessitating a second opening, which was followed by scraping and the application of iodin. The sinus on the outer side of the thigh, which was probably the remains of a ruptured cyst, was also thoroughly scraped. Both cavities were treated with iodin, phenol (carbolic acid), bismuth and argyrol over a period of fourteen weeks without any attempt at healing from the bottom, although both contracted in circumference. There was still a free secretion of clear fluid.

In view of the effect of the Roentgen ray on old tuberculous sinuses, many of which will heal under its influence, the patient was given a four-minute exposure with a hard tube. At the end of ten days both sinuses had begun to fill in at the bottom. Three other similar exposures at intervals of ten days completed the cure.

The laboratory report on the scrapings removed from the cavity was not conclusive, owing, no doubt, to the fact that the specimen was taken at the second operation and did not include enough of the lining membrane to determine its exact nature. It would seem, however, that from the delicacy of the lining membrane, the multilocular character of the cyst and the rapidity and force of its growth, the case should properly be classified under the head of hygroma.

Therapeutics

PREVENTION IS GREATER THAN CURE

(*Continued from page 1761*)

IX

EUGENICS

This very large social, economic, medical, religious and legal subject should receive a passing thought in this series on preventive medicine.

Briefly, heredity and environment are the two factors that are most prominent in the production of physical and mental health. Environment may improve or mar heredity, but cannot change it. Heredity is therefore the most important factor in raising and developing an ideal race. Scientific selection in breeding animals and plants has proved its value beyond all possible refutation. The importance of good environment for the perpetuation of physical and mental health is so well understood that it requires no discussion. But environment will not eliminate a hereditary tendency to disease or to mental or physical insufficiency. Neither will environment develop perfect mental and physical health when there is an inherited deficiency, although environment can markedly improve deficiency caused by injury or acquired by disease.

The long gestation, still longer nursing, and yet longer helpless period of the human emoryo and human infant demand the long nourishing care of the mother by the father and by the community. This means that *for at least two years* the father must provide food, protection and comfort, if not luxury, for the mother and child as well as for himself. If he fails in this duty, some other person, some charity, or the community must assume the duty. This being the fact, worthless, incapable and mentally or physically diseased fathers are a tax on the community.

All kinds of beautiful and necessary charities are succeeding in their aim to raise to adult life defective children, as well as to save the well and strong. A large number of these mentally, physically, and often through heredity, morally defective persons assert the right to marry, and do so, and another crop of defective children is the result. Our orphan asylums, hospitals, sanatoriums, homes, insane asylums, jails and prisons are being overfilled in consequence of the foregoing conditions. What are we going to do about it?

The *environment of* prospective fathers and mothers and their future children is being constantly improved by the public health advances now being made in all communities, but as has been stated, this will not prevent the ravages of inherited disease (syphilis, epilepsy, insanity, imbecility, physical weakness) or of the inherited tendency to disease (tuberculosis, cancer, gout, diabetes, alcoholism, etc.), any more than environment can produce twins, beauty, geniuses or permanent health. In fact, improved environment is doing more for the defectives in all lines than for those of good heredity, who would survive a less improved environment.

The question for discussion, then, in this one on eugenics is, who shall marry, and who shall have children? It seems doubtful whether the law or the state can, in the present status of the human age and of civilization, enforce scientific selection or compel complete physical and mental examination of a man and woman before they may be allowed to marry. Public health and welfare education, medical teaching and instruction, and the higher education emanating from the church may, in a few decades, make this problem one that is readily decided by the families of the contracting parties, or even by the young man and young woman most deeply interested. On the other hand, it is possible that the age is ripe for an insistence that known defectives and known diseased individuals be allowed to marry only when the other member of the contracting parties is made cognizant of the fact, and also that means be taken to prevent offspring from such alliances. Such defectives often breed readily and lavishly, and their progeny are often no comfort to themselves, and are more than likely to become a future, *if not an immediate, tax on the community* and state. This brings up the question of either prohibiting marriages of defectives (known to be such through public charities or public institutions and hence not ascertained by the compulsory examination of private individuals), or of legal sterilization of such defectives.

THE SCHOOL QUESTION

The following are a few suggestions of important subjects that medical men should impress privately on their families and publicly in their communities:

1. A child should be healthy before it goes to school (adenoids, tonsils, teeth, anemia, debility, etc.).
2. The kindergarten methods of teaching should be investigated, as some parts of this teaching are objectionable, and especially should the eyes of these young children not be overtaxed.
3. The best age for a child to attend a kindergarten is from 4 to 6 years; but the ordinary child at 6 years of age is too young to enter real school work. It would be ideal, from a physical point of view, if the child could then have one year, or in some instances two, in a "play school," combining physical exercise with moral and mental development. Then the child would be well fitted to attend real school.
4. The location of school buildings is important, and the architecture and equipment of such buildings are very important.
5. There should be well-equipped playgrounds in all cities.

6. The books, pencils and other school paraphernalia should be antiseptically cleaned, and clean aprons could well be provided for dirty kindergarten children.

7. Teachers should be mentally efficient, and should be physically examined at regular intervals as to their health. A physically and mentally "fit" teacher is essential for good school work.

8. Open air or open-window schools, and luncheons for underfed children should be inaugurated.

9. Kissing and the exchange of pencils and penholders among children should be discouraged.

10. There should be a trained nurse attached to each large school.

11. There must be medical inspection, if not medical examinations.

12. There should be segregation for feeble-minded, as well as for otherwise defective children. Anemic children, and those with a tuberculous tendency should be in open air rooms.

13. Night schools should have medical and sanitary supervision, especially if such schools are held in the rooms occupied by the children in the daytime.

14. The crime of child labor should be prevented.

SCHOOLHOUSES

The location of the city school cannot always be carefully selected; the school must be placed where it is most needed. The country school, however, should be located high and dry, and with a careful consideration of its sanitation, that is, its water-supply and the proper management of its sewerage system.

There is no excuse for having a country school more than two stories, and if possible, a city school should be but two stories high. The frequent going up and down of long flights of stairs is especially bad for growing girls. The light should be sufficient, and should not shine directly into the pupils' eyes, but should best enter the room from the left and the rear. The blackboards should be so placed as to receive the best light. The temperature should be from 65 to 68 F. Moisture should be sufficient, but not excessive.

The desks and chairs should be very carefully selected, and one or both should be adjustable as to height. Even with such adjustment the children should not be kept too long sitting, but should have walking, or simple calisthenic exercises to stimulate the circulation and ease the muscles.

The floors should be hard finished, so that they may be readily cleaned with vacuum cleaners, and the furniture should be such that it can be readily cleansed with antiseptics, when such are needed. In fact, daily washing of the floors with some antiseptic may be advisable. The toilet and washing arrangements should be of the best, and sanitary drinking facilities should be installed in every school.

Some one or more rooms should be arranged as open-window rooms. Every large school should have a private examining room for the use of the examining physician and the trained nurse. Every school, if possible, should have a properly equipped playground.

HOURS IN SCHOOL

The kindergarten is undoubtedly good for children whose mothers cannot care for them and who otherwise would be on the street, but the kindergarten teaching is often bad for children who are already pushed mentally in their own homes. We are not sufficiently careful to prevent mental fatigue in schoolchildren, and the number of hours generally devoted to school work is much too great. R. O. Clock[1] has studied this subject, and makes suggestions which should be carefully considered. He believes that from 7 to 8 years of age two hours of actual school mental work is sufficient; from 8 to 9, two and one-half hours; from 9 to 10, three hours; from 10 to 12, four hours; from 12 to 14, five hours. The longer periods should, of course, be broken up into two sessions. At all ages the sessions should be interrupted with from fifteen to thirty minutes' recess for fresh air and relaxation. It has been ascertained that a child at 6 has brain fatigue and his attention tires after fifteen minutes of concentration; from 7 to 10, after twenty minutes of concentration; from 10 to 12, after twenty-five minutes of severe work; and from 12 to 16 after thirty minutes. The best brain work has been found to be accomplished in the morning, and fatigue is more rapid in the afternoon, and more rapid when there are bad air and dark or overheated rooms. The brain activity is increased after gentle muscle exercise; hence the advantages of calisthenics and recesses.

It is little less than a crime to spur on brain work without proper exercise and outdoor play, and some pupils, little more than children, are stimulated to mental overactivity and to attain high standing without regard to whether or not they have time for fresh air. Before the age of 12 years a child should not be required to study at home. The crime of pushing children forward, rushing their advance from one grade to another, should cease. The child should advance by natural ability and natural progress. Cramming and pushing to get a certain amount into his brain at a certain date, and then to get him out of his grade into another to make room for one who is being pushed and crammed in the grade below should be abolished.

OUTDOOR EXERCISE

Playgrounds, and regular hours for their use, and the occasional presence and direction of games or exercises by a physical instructor, all work for the great good of the future sturdy citizen.

Weak children should not be allowed to play or exercise to exhaustion. Also, even with strong children, the necessity for bodily repair by rest periods should be urged. The story of nutrition, metabolism and elimination of waste products, and the repair during rest should be understood by all teachers. The bedtime hour for children of different ages should be taught by the teachers.

Competitive physical, and even mental tests or stunts are bad, very bad for some. It is always injurious for growing boys and girls to sustain long physical strain, and it should not be allowed by school boards in schoolchildren. This does not mean that under proper jurisdiction there should not be baseball games for boys and basketball games for girls, etc., but competitive stunts, as just stated, should not be allowed. Secret societies which cause jealousies and cliques and ill feelings should not be allowed, although certain open, non-secret societies whose membership is reached by good work and whose object is to accomplish good work are often excellent training.

(To be continued)

WHAT RENDERS A DIET INADEQUATE?

In the nutrition investigations of the present period there is an unmistakable tendency toward emphasizing the qualitative aspects of the dietary quite as prominently as the purely quantitative features of the food intake. The appreciation of the importance of an adequate supply of food units has become wide-spread in the ranks of the layman as well as the specialist. The need of energy for the working of the human mechanism has become quite as self-evident as is the necessity of fuel in the omnipresent automobile. The principle of the conservation of energy and matter is recognized on all sides. The less familiar conception of the specific rôle of certain food substances is only beginning to make its influence felt. The story of the vitamins and the part they may play in the pathogenesis of such diseases as beriberi and scurvy is preparing the way for a wide-spread interest in what has hitherto been relegated to a minor part in nutrition.

Writers on animal nutrition have long employed the expression "balanced ration" in connection with feeding practices in modern agriculture. By this they refer to a mixture of the nutrients in which the proteins, fats, carbohydrates and inorganic ingredients are present in certain relative proportions. The requirement of an irreducible minimum of protein and of inorganic salts has become obvious; but how inappropriate even the so-called balanced ration may be under some circumstances was plainly demonstrated in the Wisconsin experiments with cattle[1] in which failure followed the attempt to supply the nutrients from a single plant source. It is evident that there are details of composition with respect to the food-supply which scarcely suggested themselves in the cruder surveys of the nutrition situation, but which nevertheless spell success or failure in any prolonged dietary regimen.

The reason that the importance of hitherto unsuspected features was not recognized earlier may lie in the fact that most individuals are accustomed to a fairly wide range of food products—a condition under which deficiencies in minor though important, constituents are less likely to arise. The extremes in nutrition are therefore most likely to appear under experimental conditions; and in this field of knowledge, as in so many others, the laboratory animals have furnished new and useful points of view from which to approach the problems of the human dietary. In illustration we may refer to the newest studies from Professor Hofmeister's laboratory in Strassburg published just prior to the outbreak of European hostilities which threaten to put an end to so much of the best in the medical sciences of to-day. Oseki[2] had shown that it was possible to keep mice in good nutritive condition for considerable periods of time on a diet of coarse rye bread, the *Kommissbrot* of the Germans. This product may accordingly be designated as a food both quantitatively and qualitatively adequate for the species investigated. It appears, however, according to the newest experiments of Tachau,[3] that additions of apparently innocuous substances, including sugar, fats and certain salts, may suffice to render these appropriate diets no longer suitable for adequate nutrition.

The conversion of a diet which seems to meet the requirements of an animal satisfactorily, into one obviously inappropriate, by the mere superposition of products that commonly enter into the dietary, would scarcely have been suspected a few years ago. In the mice under consideration the disproportions in the food, produced by large additions of sugar or fat, resulted in gradual decline of body-weight ending in death. To explain this, various hypotheses suggest themselves. Anorexia may have resulted from the "one-sided" diets, leading to gradual inanition from insufficient food intake. The digestibility of the ration may have become impaired by the unusual preponderance of individual foodstuffs. The upset in the usual interrelations of protein, fat and carbohydrate may have made itself felt in some feature of intermediary metabolism. After all, it matters little whether any or all of these explanations apply in this case. The lesson to students of human nutrition lies in the warning that much remains to be learned before we can pronounce the final word with respect to what constitutes a balanced ration.

In Tachau's experiments some of the animals received additions of undue amounts of certain salts—sodium chlorid, sodium phosphate, sodium sulphate, sodium lactate—to the otherwise suitable ration. In these cases, in contrast to what happened when the organic admixtures were added, upsets in the osmotic phenomena of the organism frequently made their appearance, leading to an abnormal distribution of water and the exhibition of edema. The production of this symptom by the continued administration of salt in large quantities belongs among experimental novelties. An added interest is attached thereto because a similar phenomenon has been described in infants after ingestion of excessive quantities of salt.[4] In the adult "latent" accumulations of fluid do not become evident so readily in the same way.

THE SIGNIFICANCE OF GLYCURONIC ACID

How sugar is burned up, or metabolized in the organism is a question that interests every one who has to deal with the nutritive functions of the body either in health or disease. The discovery of glycuronic acid, $COOH.(CHOH)_4.CHO$ — a compound closely related to glucose and other carbohydrates and derived therefrom by slight oxidation—as an occasional constituent of the excretion early gave occasion for the speculation that it is derived from carbohydrate in the body. A further step in the way of hypothesis has been to look upon glycuronic acid as an intermediate product of sugar destruction—a stage in the physiologic conversion of the carbohydrate into its final end products, water and carbon dioxid. The fact that when certain toxic products, like menthol, camphor, and many other substances, particularly alcohol derivatives, are introduced into the organism they are eliminated as conjugated glycuronates in no way controverts the hypothesis; for it is easily conceivable that the noxious substances of an alcoholic type combine with glycuronic acid as it is formed, and by uniting with the latter in transit, as it were, through the process of metabolism, they become detoxicated prior to their elimination.

To postulate that any substance represents an intermediate step in the disintegration of a foodstuff in metabolism implies that it is itself easily destroyed in the organism and, under ordinary circumstances does not make its appearance anywhere in the body in any quantity. The failure to meet these criteria ought, we believe, to take a compound out of the category of an intermediate product. These statements apply, of course, only under conditions of health and reasonable feeding. Sugar is a normal product easily consumed by the body; yet there are conditions of disease, like diabetes, in which it fails to undergo the usual conversion into end products.

Glycuronic acid has already been investigated with a view to securing answers to the questions raised. Mayer[1] has reported an apparently ready destruction of this substance when it was introduced into the organism, and his studies have formed the basis for the textbook statements that glycuronic acid is ordinarily readily burned up in the body. The experiments of Mayer are now directly contradicted by the newest researches of Biberfeld[2] at the pharmacologic institute of the University of Breslau. In these, glycuronic acid was recovered almost quantitatively unchanged when it was introduced parenterally into animals. The suggestion thus afforded of the improbability that glycuronic acid is an intermediate stage in the oxidation of the carbohydrates is strengthened by the comparable physiologic indestructibility of other acid oxidation products of the sugars. Neither gluconic acid, $COOH.(CHOH)_4.CH_2.OH$, nor saccharic or mucic acids $COOH.(CHOH)_4.COOH$ are readily destroyed in the body. These facts point to glycoronic acid as an abnormal rather than normal stage in metabolism.

ABSORPTION OF THE CEREBROSPINAL FLUID

Of the problems connected with the cerebrospinal fluid, some of which have been discussed recently in these columns,[1] that of the paths of absorption of the fluid has been the subject of much interest. Key and Retzius, Quincke and others showed the continuity of the cranial and spinal subarachnoid spaces, in which the fluid is found, and held, with most later observers, that absorption takes place by way of the venous sinuses through the pacchionian granulations and the lymphatic system.

The methods of study have comprised the microscopic examination of the meninges, which has revealed nothing conclusive, and the injection of suspensions of granules, of viscous fluids, of emulsions or of true solutions. The injection of anything but true solutions is open to the serious objection that the paths sought are those of the absorption of an easily flowing fluid and not solids or clogging fluids, which are caught in the meshes of the arachnoid. Weed[2] gives the results of the injection of a true solution of potassium ferrocyanid and iron ammonium citrate into the subarachnoid spaces during life, with subsequent precipitation of Prussian blue wherever the fluid penetrates in the head and neck by fixation of the tissues *in situ* by a 1 per cent. solution of hydrochloric acid in liquor formaldehydi.

By this method, Weed concludes that the chief pathway of absorption is the venous sinuses. After injection of the fluid into the spinal subarachnoid spaces, he finds the path taken by the fluid to be throughout the cranial subarachnoid spaces, and thence, by way of "arachnoidal villi," into the great sinuses. The sinus into which this occurs chiefly is the superior longitudinal, but practically all the others take some part in the drainage.

That the absorption is chiefly cranial Weed believes is shown by the much more rapid absorption and excretion in the urine of phenolsulphonephthalein from the cranial spaces than from the spinal, after ligation of the cervical cord and meninges. He finds that the cerebral, as distinguished from the pachymeningeal, vessels play no part in the drainage of the fluid under normal conditions of pressure, and that the subdural spaces are excluded from participation in this escape, since no connection exists between them and the subarachnoid spaces.

[2] Weed· Jour. Med. Research. 1914. xxxi. 51.

The path of escape from the subarachnoid spaces into the sinus he finds to be the "arachnoidal villi." These are projections of arachnoidea into the wall of the sinus, usually about veins entering the sinus, and most numerous in those areas where the great cerebral vessels enter. The arachnoidal tissue, as it passes backward and inward in the wall, becomes myxomatous, and is capped at its end, where it lies in close apposition to the endothelium of the sinus, by one or many layers of mesothelial cells, through which and the endothelium the fluid enters the lumen. Usually these villi are confined to the wall of the sinus, but in adults they may be seen projecting into the lumen, and the myxomatous portion forms the groundwork of the pacchionian granulations. Weed states further that projections of arachnoidal mesothelial cells occur in all portions of the dura, especially about the sagittal and cavernous sinuses, serving as intradural channels for cerebrospinal fluid, which explains the weeping of fluid from the exposed dura after removal of portions of the calvarium during life. He believes that the passage of fluid through the villi is a filtration, rather than a process of osmosis or secretion, since the Prussian blue granules are found in the cells and lumen of the sinus even with high concentrations of injection fluids, and retrograde passage of fluids occurs through the villi on obstruction of the return venous flow from the head.

The lymphatic system appears to play an accessory part in the absorption of cerebrospinal fluid, since after injection into the spinal subarachnoid spaces, Prussian blue is found in the cervical lymph-channels and glands and in the perineural lymph-spaces of the cranial and spinal nerves. About the olfactory nerves, in the meshes of the connective tissue reticulum and in the lymphatic channels of the nasal mucous membranes, large amounts of Prussian blue are found. Weed cites several cases in which fluid containing potassium ferrocyanid ran out of the nose during injection. This drainage seems to occur in a like manner, but to a lesser extent, along the other cranial and spinal nerves.

Briefly, then, we may conclude from the results of Weed's valuable work that the escape of cerebrospinal fluid is chiefly by filtration through arachnoidal villi from the subarachnoid spaces into the venous sinuses, with an accessory path from the perineural spaces of cranial and spinal nerves through the tissue spaces about the nerve to the lymphatic vessels.

SOME FEATURES OF BONE GROWTH

Although calcium is admittedly an indispensable constituent of the diet, the need of this element is far more acute during the period of growth than in adult life when the bony structures, rich in lime and other tissues, have been fully developed. The period of gestation — in reality, likewise a period of growth in a special sense — is excepted, and also the time of lactation, when milk comparatively rich in calcium is being secreted in abundance.

A deficiency in the intake of calcium during the period of adolescence is more than likely to entail disturbances in the development of the osseous tissues. This is, of course, a fact too familiar to admit of discussion here. Nevertheless, the actual character of the bone defects which result from such deficiency is by no means so certain as the supposed familiarity of the subject would lead one to conjecture. Perhaps the morphologic pathologists are confident of their ability to recognize a bone rendered defective from the lack of the essential lime salts. The pathologic chemist is far from convinced as to the indications of abnormal composition under these circumstances. Has not the problem of rachitis and of osteoporosis remained a topic of controversy until the present day?

The lack of satisfying knowledge with respect to the effects of a shortage of calcium in the diet is attributable in the case of the human subject in largest measure to the inability of the student to examine material from suitable cases. Comparatively few investigators have contributed tissue analyses bearing on this topic. Furthermore, the variations in the food intake of the growing infant or child are rarely extreme with respect to their deviation from the normal, so that the effects are never very pronounced and are likely to be concealed when they are contrasted with the broad range of a "general average." For these reasons our best information has come and is further likely to come from carefully planned experiments on animals during their period of growth.

Very recent studies by Weiser[1] in Professor Tangl's institute at Budapest are of peculiar interest, because they involve experiments on growth with diets differing solely in their content of calcium. The ration poor in calcium contained 0.055 per cent. of this element, in comparison with 0.448 per cent. in the comparable dietary. The prolonged lime-poor feeding brings about very apparent changes in growth, which early manifest themselves in undersize or underweight by contrast with control animals. If the calcium deficiency is continued the appetite fails and then nutritive decline may actually ensue. There are, of course, extreme conditions for actual practice, yet they are the outcome of diet deficiencies that are not apparent to the eye and sometimes call for very expert knowledge.

---

[1] Weiser, S.: Zur Kenntnis des Einflusses kalkarmer Nahrung auf die Zusammensetzung der wachsenden Knochen, Biochem. Ztschr., 1914, lxvi, 95.

How many mothers, or even physicians, realize that corn and meat, for example, are very low in calcium? Are they informed as to the distribution of calcium in common foods?

The bones of the individuals deprived of sufficient calcium exhibit a physical make-up that may readily reveal itself in a cursory examination. They are likely to be thin, pliable, deformed and fragile. The skeleton is not necessarily retarded in its external growth, but the bones supplant part of the lack of mineral constituents by an added richness in water.

One of the novelties revealed in Weiser's research is the unexpected presence of not inconsiderable quantities of alkalies—sodium and potassium—in the lime-poor bones. Magnesium, which has been believed by some to replace the calcium when the latter is not available, is after all not correspondingly conspicuous. The changes in the distribution of the inorganic components of the bone are not alike in all parts of the skeleton. The deviations are least conspicuous in the skull and most prominent in the ribs and spinal vertebrae. Many of these facts here elaborated from recent researches have been demonstrated in the past. They will bear repetition so long as the rôle of specific components of the diet is not appreciated more deeply than it appears to be at present in medical circles.

AS TO SANATOGEN

For several years it has been known by physiologists that all proteins taken into the stomach are disintegrated into their fundamental components, the amino-acids, and that they are not absorbed at all as proteins, except in most minute amounts under exceptional conditions. Therefore, no matter what protein is taken as food, the material obtained from this protein by the body is a group of amino-acids, always pretty much the same except in relative proportions, whatever the food. A few proteins lack certain essential amino-acids, but any ordinary diet supplies enough, and more than enough, of each and every amino-acid. Furthermore, since the proteins are completely disintegrated before absorption, it follows that any adventitious chemical substance that is bound to a protein taken in the food does not enter the blood and circulate in the body in the same protein compound.

All the facts stated above are elementary, and should be known by any and every physician who pretends to keep even approximately abreast of the science of medicine. If there are any who do not know these fundamentals, and from certain unwelcome evidence we fear there are, they must be resigned to being told just where they stand. Certainly they have no good excuse for their lack of information, for the physiologists and biochemists have informed them of modern advances in innumerable ways. For ten years and more these facts have been discussed and demonstrated in societies and in medical publications. And yet — there is Sanatogen, prescribed by Geheimrats, Hofrats and also by doctors, and testimonialed as abundantly by men with medical degrees as Duffy's whisky is by centenarians. One can merely throw up his hands. If, as the exploiters of Sanatogen declare, the product "has been endorsed by von Noorden, Ewald, Dührssen, Eulenburg, Neisser, Binswanger, Leyden, Krafft-Ebing, Tillmanns, Tunnicliffe and thousands of other earnest, reputable physicians," we can only say that their earnestness has not been in the direction of grasping fundamental advances in medical sciences, however great the reputation they have gained may be.

In this issue[1] we print another report of exact experimental observation which shows, as was obvious beforehand, that Sanatogen has the properties of its constituents, namely, casein and glycerophosphates. Nothing more nor nothing less could be the case. Bottling dried cottage cheese plus some glycerophosphates, and raising the price many times, may increase its psychic effect, but it will not alter its physiologic action. These facts we have presented often enough, but the amount of paid advertising the proprietors of this compound find it profitable to carry in the United States makes us feel obliged to give them this bit free. That laymen may be persuaded to purchase Sanatogen in the belief that it possesses some occult powers not to be found in its constituents is not surprising. By blatant and persistent advertising, the public can be fooled into buying any product — however valueless — for which medicinal claims are made. But that physicians should prove equally gullible is a sorry commentary on the scientific attainments of the followers of a learned profession.

NEW EXPERIENCES WITH INTRAVENOUS NUTRITION

Not long ago we called attention to the successful experiments of Henriques and Andersen of the physiologic institute at the University of Copenhagen in the field of intravenous nutrition.[2] They succeeded in keeping animals alive for very considerable periods of time by the device of a continuous intravenous injection of nutrients, either by way of the jugular vein or through a splenic vein. By such parenteral "feeding" of completely digested proteins, together with suitable non-nitrogenous food materials, it was possible to secure retention of nitrogen, that is, positive or favorable nitrogen balances in the organism. Inasmuch as the nitrogen in such nutrient solutions was supplied essentially in the form of amino acids, not only is their significance for the nutritive functions thereby conspicuously demonstrated, but also the probability of a pro-from the cranial spaces than from the spinal, after ligation of the cervical cord and meninges. He finds that the cerebral, as distinguished from the pachymeningeal, vessels play no part in the drainage of the fluid under normal conditions of pressure, and that the subdural spaces are excluded from participation in this escape, since no connection exists between them and the subarachnoid spaces.

---

[1] Weiser, S.: Zur Kenntnis des Einflusses kalkarmer Nahrung auf die Zusammensetzung der wachsenden Knochen, Biochem. Ztschr., 1914, lxvi, 95.

may accordingly be interpreted in the form of emotional states. Inasmuch as the sympathetic nervous system is closely involved in the functioning of the internal organs and the blood-supply of different parts of the body, the logic of the situation leads one to inquire into a possible interrelation between all of the factors here discussed, particularly the association of dispositional changes following castration with alterations in the sympathetic system. Dr. Wheelon[1] of the Northwestern University Medical School in Chicago has made a careful comparison of certain vascular responses in dogs before and after removal of the testes, in order to secure information as to the effects of such operations on the general functions of the body. His work indicates that normal blood-pressure is only slightly changed as a result of gonadectomy. The irritability of the myoneural junction of the arterial walls, as determined by comparative responses to the same dosage of epinephrin, was constant, within the limits of experimental error, before and after castration. Sympathetic irritability, on the other hand, was clearly lowered after the operation. This was ascertained by the behavior of the circulatory system to nicotin, which was used as a vasomotor stimulant in these cases because of its selective action on the sympathetic nervous system. The evidence was made more convincing by the added fact that testicular grafts were apparently found to restore irritability in castrates practically to normal. Wheelon concludes that a relationship actually exists between the normally functioning testes and the irritability of the sympathetic nervous system proper. Deprived of these sexual organs, the individuals exhibit structural changes followed by alterations in their physiologic and emotional processes.

THE AVERAGE DURATION OF SICKNESS

It is recognized that much of our data regarding disease is practically valueless because the statistics recorded in different localities and for different purposes are not intelligently coordinated. The facts are on record, but the deductions which can be drawn only from carefully tabulated facts are too often lacking on account of the incompleteness of the records. One of the most promising features about the present public health situation is that the facts regarding disease are beginning to be subjected to the same careful scrutiny and mathematical analysis that have in previous years been given to life insurance tables and other tabulations of business facts. The Prudential Insurance Company of America has issued a reprint containing an address before the National Organization for Public Health Nursing, on "Practical Statistics of Public Health Nursing and Community Sickness Experience," by Mr. Frederick L. Hoffman. After commenting on the well-known lack of uniformity in recording the statistics of visiting nurses, of terminology and of completeness of records, Mr. Hoffman presents the statistics of visiting nurses' associations for Baltimore, Boston, Chicago and Philadelphia for 1912 and 1913. Tabulating these reports, he finds that the four associations in one year gave attention to 58,933 patients, making 429,620 calls, or an average of seven calls per patient. After discussing the general condition of hospitals and hospital treating throughout the country in an endeavor to establish the essentials of an analysis on this subject, Mr. Hoffman finds that the average duration of sickness, as far as can be determined from the fragmentary records, was eleven days for ages under 44 and twenty-three days for ages over 45, and that the average nursing duration for sickness for patients over 45 is seventeen days for males and twenty-five days for females. Many other interesting facts and deductions are presented. Mr. Hoffman's painstaking study of a large mass of hospital reports and statistics is of distinct value, although the most important point emphasized is the meagerness and incompleteness of our data.

AMINS AND URTICARIA

In a recent issue of The Journal, attention was directed to the occurrence of preformed amins in the foods we eat.[1] It was there pointed out that many of these products derived from bacterial decomposition of proteins are already known to exhibit pharmacologic potency, such as an unmistakable effect on blood-pressure, as well as other physiologic phenomena. We are now reminded of an interesting and novel observation by Eustis[2] on the action of one of these amins—betaimidazolylethylamin, derived from the amino-acid histidin. The introduction of a very small amount of this substance through superficial abrasions of the skin promptly gives rise to a localized edema resembling urticaria. This fact has prompted the assumption that betaimidazolylethylamin formed in the gastro-enteric tract may be responsible for urticaria of alimentary origin.[3] On this hypothesis a rational dietotherapy of such urticaria is at once suggested. Eustis proposes, for example, effective purgative treatment along with abstinence from protein in the diet for some days. He says that the intestinal toxemia can readily be judged by frequent examination of the urine for indican, the presence of which is used as a guide to the allowance of the amin-yielding protein in the diet. There are various theories as to the origin of urticarias. Some of the cases of the disease are singularly intractable. Doubtless they have a manifold cause or origin. The amin hypothesis is surely not without significance.

The Uniqueness of the Individual.—It is impossible to make the inevitable course of a man's destiny comprehensible in all details. Every man from his birth to his death is a unique phenomenon with no exact counterpart in the past or in the future. The observer understands things only within the limits of his own peculiar nature.—Gerhardt Hauptmann.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Personal.—Dr. Rudolph H. Kocher has been appointed instructor in research medicine in the Hooper Foundation of Medical Research of the University of California, Berkeley. ——Dr. James W. Keeney, San Francisco, is reported to be critically ill at his home.——Dr. Fletcher G. Sanborn returned to his home in Los Angeles, October 24, after an absence of eight months in charge of the Hospital Uyak, Alaska.——Dr. Benjamin F. Walker, Stockton, is in charge of a special first-aid corps organized by a Parisian banker.

New Medical Building.—Working drawings have been completed for the new pathologic building to be erected by San Francisco at the city and county hospital site. The plans call for a two-story building, 97x155 feet. This will contain on the first floor an operating amphitheater, human and animal rooms, inside and outside kennels for housing animals for scientific investigation, a specimen department and cadaver room. On the upper floor will be located two laboratories with the necessary preparation and animal rooms.

COLORADO

Personal.—Dr. J. E. Perkins, mayor of Denver, recently visited Indianapolis to study and inspect the activities of the health board and other departments of the municipal government.——Dr. Franklin E. Wallace, Pueblo, has been elected a member of the state legislature.——Fire in the McPhee Building, Denver, October 3, seriously endangered Dr. Walter A. Jayne who was asleep in his apartment when the fire broke out. He was overcome by smoke, but was rescued by the fire department.

Health Seekers Bureau of Denver.—At a recent meeting of the Denver physicians, the tuberculosis supervisor of the Denver Visiting Nurses' Association told of his work of setting incoming health seekers on the road to life and strength. The physicians adopted a resolution indorsing the work of the supervisor and volunteered to have one of their number assist him during his office hours. Health seeking new comers will find at the rooms of the Denver Visiting Nurses' Association at Fifteenth and California Streets, not only the supervisor, but a physician who will give them an examination and advice between 9:30 and 11 a. m. on Mondays and Thursdays.

GEORGIA

Atlanta Roentgenologists Organize.—On October 29 the Atlanta Roentgen-Ray Society was formed, with an initial membership of fifteen. Pending the adoption of a constitution and by-laws, Dr. George M. Niles was made acting president and Mr. B. E. Sale, acting secretary.

Pellagra and Hookworm at Milledgeville.—The Georgia State Sanitarium at Milledgeville has been selected by the United States government as a station for experimental work in pellagra cases. The patients will be segregated and kept under special treatment and diet, the work being done under the charge of two experts of the United States Public Health Service.——According to examinations made by specialists from the State Board of Health, the percentage of hookworm infection is about 50 per cent. It is estimated that 1,000 cases exist in Baldwin County.

ILLINOIS

Personal.—Dr. William A. Diffinbaugh, Dundee, was thrown to the ground while cranking his automobile, October 23, and fractured his ankle. He is under care in the Sherman Hospital, Elgin.——Dr. Anthony G. Wittman, of the staff of the Elgin State Hospital, has been made medical director of the new Alton State Hospital.

Tuberculosis Dispensary Opens in Quincy.—The dispensary established in Quincy by the Adams County Tuberculosis Association was opened for the inspection of the public November 7, and received patients on the following day. The dispensary will be open on Mondays, Wednesdays and Fridays at hours to accommodate all classes of people.

Elgin Superintendent Seeks Betterments.—Dr. Henry J. Gahagan, superintendent of the Elgin State Hospital, has asked the State Board of Administration for a tuberculosis hospital at an estimated cost of $50,000, a building for incurably insane women at an estimated cost of $35,000, an extension to the dining-room of the institution, and an addition of 500 acres of land to the hospital farm.

Chicago

City to Establish Public Laundry.—Health Commissioner George B. Young announced November 13 that one of the Municipal Bath Houses will soon be turned into a Municipal Laundry for the benefit of the women in the tenement districts.

Anti-Typhoid Inoculation in Holland.—Dr. Caroline Hedger has been asked to go to Rotterdam, Holland, taking with her antityphoid vaccine sufficient for 10,000 Belgian refugees in Holland, where typhoid fever has already appeared. The Chicago Woman's Club has already contributed $300 toward Dr. Hedger's fund. The antityphoid vaccine has been offered free.

Physicians Urge Increased Hospital Accommodations for Contagious Diseases.—Members of the Chicago Medical Society, speaking before the Association of Commerce, November 4, appealed for enlarged hospital accommodations for cases of contagious diseases. It is said that there are more than 40,000 cases in the city every year and that only about 10 per cent. of the number are sent to hospitals; also that the lack of hospital facilities causes failure to report many cases of contagious diseases to the health commissioner for quarantine.

Morals Board Plan.—The council committee on health has recommended the creation of a morals commission of five members whose work will be to study immorality in all its forms, its causes and effects; to recommend measures for the prevention of venereal disease; to report violations of the state laws or city ordinances covering immorality; to study the legal action necessary for the supression of disorderly resorts within three miles of the city; and to recommend measures for the physical and mental rehabilitation of fallen women. The commission is to make reports from time to time to the mayor and city council.

INDIANA

Eye Inspection Ordered.—The Indianapolis City Board of Health has ordered an inspection of the eyes of all school-children, with special reference as to their ability to see ordinary type at an ordinary distance.

Small-Pox in Whiting.—E. L. Dewey, commissioner of the department of health, states that since October 14, sixty-one cases of small-pox have been reported to his department. This department established an isolation hospital October 10. Sixty-one patients have been admitted since that date, and thirty have been discharged. Dr. Edward K. Newton is the resident physician, assisted by four graduate nurses. All children admitted to the public and parochial schools must be successfully vaccinated. Nearly all of the new cases developing are unvaccinated adults. One thing very noticeable about this epidemic is that of variety of types of the disease. One baby aged 3 weeks was admitted on the fifth day of the eruption, a typical confluent type. Those unvaccinated adults for the most part are severe discrete types, a few confluent.

KENTUCKY

Trachoma in Butler County.—Dr. James O. Carson, Bowling Green, with his assistant, spent from October 27 to 29 in Butler County inspecting for trachoma the eyes of the children of fifteen school districts on the north side of Green River. Dr. Carson will make a report of his findings to the State Board of Health, and will also lay the matter before the United States Public Health Service in the hope that a treatment station may be established in this section of Kentucky.

LOUISIANA

Postgraduate School Opens.—The New Orleans Post-Graduate School of Medicine opened for its first session October 26. Dr. Homer J. Dupuy, Jr., is president; Dr. Wilhelm Kohlmann, vice-president, and Dr. Joseph A. Danna, secretary, of the institution. The faculty is composed of staff members of the Charity Hospital, Touro Infirmary, Hotel Dieu and the Presbyterian Hospital.

Reciprocity with California.—At the meeting of the Louisiana State Board of Medical Examiners, October 29-31, a resolution was adopted that the board would accept for registration without examination in Louisiana, all applicants from California who can comply with the rules governing reciprocity with Louisiana. The board announces that an examination will be held in New Orleans, June 3 to 5.

Personal.—Dr. Espy M. Williams, Patterson, has resigned from the Louisiana State Board of Medical Examiners on account of his removal from the Fourth District, and Dr. Leon J. Menville, Houma, has been appointed to fill the vacancy.——Dr. George W. Lewis, New Orleans, fell October 26, fracturing his left arm at the wrist.——Dr. Arthur W. De Roaldes, New Orleans, who has been ill with pneumonia, is reported to be convalescent.——Dr. Allen J. Perkins, Lake Charles, while driving near Mallard Junction, October 23, narrowly escaped death when a magazine shotgun was discharged at his buggy.

MARYLAND

Personal.—Dr. Joseph W. Holland, Baltimore, has been elected vice-president of the Queen Anne's County chapter of the Eastern Shore Society.——Dr. Frederick H. Baetjer, Baltimore, who was operated on for the removal of glands near the shoulder, October 30, is reported to be doing well.

Adler Memorial Annex Dedicated.—The Adler Memorial wing of the Children's Hospital School, Baltimore, was dedicated on November 12, Dr. Frank T. Goodnow, president of the Johns Hopkins University, making the principal address. The new wing, which is the gift of Simon C. Adler, contains twenty-four beds on the second floor. On the floor below there is a room for the children's use as a playroom, a diet kitchen and a room for Roentgen-ray work.

Foot-and-Mouth Disease in Maryland.—On account of the epidemic of the foot-and-mouth disease among the cattle of Maryland, Dr. Nathan R. Gorter, Commissioner of Health of Baltimore, has issued a proclamation cautioning the public to heat all milk to the boiling point before using, in order to destroy the infection. The state veterinarian is making a thorough investigation and immediately quarantining all dairies and herds where the disease is discovered. Shipment of milk from such dairies is prohibited by the State and City Health departments and by the State Live Stock Sanitary Board. The City and State Health departments are cooperating with the Live Stock Sanitary Board in the warfare on the disease, and men from these departments have been sent to Highlandtown and to Howard County to see that all proper precautions are taken to prevent the communication of the disease to human beings.

MASSACHUSETTS

Personal.—Dr. Barry H. Calkin, Boston, after twenty years of practice in Jamaica Plain, has left for his new home in Nova Scotia.——Dr. Lemuel F. Noble, Boston, sailed for Europe, November 7.——Dr. Aubrey J. Collins, Boston, has been appointed a medical inspector of the health department.

Baby-Saving Sunday.—Many prominent physicians of the United States occupied the pulpits in Boston churches, October 8, preliminary to the meeting of the American Association for the Study and Prevention of Infant Mortality. In their addresses these physicians sought to show the causes of infant mortality and how it may be reduced.

Brigham Hospital Formally Opened.—Exercises in celebration of Founder's Day was held at the Peter Bent Brigham Hospital, Boston, at which the principal addresses were delivered by Drs. William H. Welch, Baltimore, and Frank Billings, Chicago, who emphasized the advantages of a teaching hospital. John P. Reynolds delivered the symbolic silver key of the institution to President Alexander Cochrane and Dr. Harvey Cushing, Boston, speaking on behalf of the staff, reviewed the difficulties of getting so large a plant into full operation and stated that he considered the proximity of the Harvard Medical School as the keystone to the hospital's future success.

MICHIGAN

Sicilian Surgeon in Detroit.—Dr. Franco Bonnarito, professor of surgery in the University of Palermo, Sicily, held a clinic and delivered a lecture at Grace Hospital, Detroit, recently.

Personal.—Dr. James Gostanian, Sault Ste. Marie, after fourteen years' practice in Baraga, has moved to Detroit, October 29. The Chippewa County Medical Society gave a dinner in honor of Dr. Gostanian at the Park Hotel, Sault Ste. Marie.——Dr. Benjamin T. Goodfellow, Clio, suffered a fracture of two ribs in an automobile accident near Clio, November 3.——Dr. James N. Garber, Detroit, who was injured in an automobile collision, October 26, is convalescent and expects to resume practice soon.——Dr. Warren H. Taylor, Flint, is suffering at his home from the effects of a cerebral hemorrhage, October 29.——Dr. Orlando E. Harvey, Howell, assistant superintendent of the state sanatorium, has resigned and will practice in Iowa.——Dr. Albert L. Laing, Escanaba, has been appointed local surgeon for the Soo Line. ——Dr. George A. Kirker, Detroit, who has been ill at his home with heart trouble for several weeks, is reported to be impfoving.

MINNESOTA

Health Body Joins Consolidated Charities.—The Municipal Anti-Tuberculosis Committee of St. Paul, on October 30, voted to go out of existence and unite with the Associated Charities of St. Paul.

Southern Minnesota Physicians to Meet.—The annual meeting of the Southern Minnesota Medical Association will be held in Mankato, December 1 and 2, under the presidency of Dr. Hugh F. McGaughey, Winona.

Personal.—Dr. Christian F. Carstens, Keewatin, has been transferred to the Rood Hospital, Hibbing.——Dr. John W. Lee, Minneapolis, who has just returned from abroad, was arrested in Dublin on suspicion of being a spy.——Dr. Eugene A. Hutchins, Minneapolis, is critically ill at Asbury Hospital in that city.

Specialists Elect Officers.—At the annual meeting of the Minnesota Academy of Ophthalmology and Oto-Laryngology, the following officers were elected: president, Dr. Edward J. Brown, Minneapolis; vice-presidents, Drs. John H. James, Mankato, and Thomas S. McDavitt, St. Paul; secretary-treasurer, Dr. John H. Morse, Minneapolis.

Diphtheria.—One hundred and twenty-one cases of diphtheria were reported in St. Paul, October 29, as against thirty cases during October last year. The health department expected soon to have all cases isolated and the spread of the disease stopped. Forty-one cases were also reported in Minneapolis by the school nurses for the week ended October 30.

MISSISSIPPI

Higher Entrance Standard.—At a regular meeting of the Mississippi State Board of Health on Oct. 26, 1914, a resolution was adopted that the definition of a reputable medical college be amended to read as follows: One which is classed as A plus or B by the American Medical Association until Jan. 1, 1919. After this date said colleges shall require an entrance qualification in addition to four years of standard high school work, one year of college work, including courses in physics, chemistry, biology and a modern language. This to apply to all who graduate in 1919, or thereafter. Those graduating before this to be allowed credit for four years or more of regular practice instead of this additional qualification. This is the twenty-fourth state to adopt this higher requirement.

MISSOURI

Anti-Tuberculosis Campaign.—Dr. Louis C. Boisliniere of St. Louis delivered a series of lectures on tuberculosis in six towns in Knox County, October 26 and 27. The campaign was conducted under the auspices of the Knox County Medical Society and was financed by the county court of Knox County.

Health Meet Postponed.—The Missouri Valley Health Congress, planned to meet at St. Joseph, November 27-28, has been postponed until some time in February on account of the wide interest manifested by the health workers. The scope of the congress will be enlarged and adequate preparations made for the meeting in February.

Physicians to Have Right of Way.—An ordinance was passed in the St. Louis Municipal Council recently, which gives physicians the right of way on public streets. Heretofore the fire department equipment, ambulances, United States mail wagons, police patrols and street railway repair wagons have been the only vehicles which had the right of way.

Medical History Exhibit.—The St. Louis Medical History Club is collecting articles for an exhibit at a loan exhibition illustrating the medical history of St. Louis and Missouri to be conducted under the auspices of the Missouri Historical Society. The exhibition will be held in Jefferson Memorial Building, beginning December 2 and will continue for two weeks.

Elected to the Legislature.—The following physicians, all reputable practitioners, have been elected members of the state legislature: In the Senate, Dr. W. Lee Welch, Mountain View, and Dr. John S. Wallace, Brunswick; in the House of Representatives, Dr. Thomas B. Cook, Rayville, Ray County; Dr. Guy B. Mitchell, Branson, Taney County; Dr. James A.

Waterman, Breckenridge, Caldwell County; Dr. James R. L. Womack, Houston, Texas County; Dr. Cassius M. C. Wilcox, Kirksville, Adair County.

NEBRASKA

Medical Fraternity Chapter Organized.—On November 2, a chapter of the Alpha Omega Alpha Society was organized at Omaha in the medical department of the University of Nebraska. The charter members being the dean, Dr. Willson O. Bridges, Drs. Irving S. Cutter, Charles W. M. Poynter, Oscar T. Schultz and Palmer Findley, and Messrs. Blaine A. Young and J. Jay Keegan.

NEW JERSEY

Dispensaries Opened.—A room in the Paterson City Hall has been asked for as a free dispensary and was opened October 31. The dispensary will receive patients at 9 a. m. and 2 p. m., and will be in charge of City Physician Dr. James F. Briody and Assistant Physician Dr. Joseph W. Williams.——The Tuberculosis Clinic for West Hudson, located at 41 Kearny Avenue, Kearny, established by the Hudson County Board of Freeholders, was opened for inspection, October 17. Dr. Alfred A. Mutter, Arlington, is in charge of the clinic.

Newark's Experience with Vaccination.—A folder with this title is now being distributed by order of the Board of Health. Among the figures given for the small-pox epidemic of 1901-1902 are the following: In 195 cases, totally without vaccination, 56 deaths resulted. Among 70 vaccinated persons exposed to small-pox in their homes, 4 deaths occurred. Among 131 cases in which the vaccination mark was more than 5 years old, there were 12 deaths. In 7 cases in which the vaccination mark was less than 5 years old, there were no deaths.

NEW YORK

New York City

Training Teachers for Defective Children.—The department of New York University for the training of teachers of defective children has 115 teachers enrolled. A clinic has been conducted in connection with this department and the indications are that its facilities will soon be taxed.

Handbook of the Bureau of Infectious Diseases.—A new edition of the Handbook of the Bureau of Infectious Diseases is now ready for distribution. Its scope has been considerably widened so that it now embraces a description of the varied activities of this bureau in all its details. It is at one time a manual of instruction for employees of the bureau and a book of information to students of this department of public health work. On request copies will be sent to those interested.

Milk Pasteurization and Foot-and-Mouth Disease.—The outbreak of foot-and-mouth disease in a large herd of cattle at Woodhaven, L. I., and possibly also at another large dairy farm on Long Island, led to the adoption at the meeting of the Board of Health, November 13, of resolutions requiring the pasteurization of all milk brought into the city. It is said that 99 per cent. of the supply is pasteurized under ordinary conditions, so that this order will not carry with it any serious hardship for dairymen.

Factory and Shop Inspection.—The Health Department has formulated plans providing for the sanitary inspection of all shops and factories in this city. The information thus acquired will be turned over to employers and employees who can then cooperate to secure any needed reforms. The department also announces that through its Bureau of Public Health it will be glad to assist in formulating sanitary industrial standards for the prevention of occupational diseases. This movement is the outgrowth of the garment workers' strike four years ago, when it was ruled that every industry should be responsible for the sanitary conditions in that industry.

Inquiry into Coroner's Officers.—This inquiry is being conducted before Commissioner Wallstein, and thus far a number of coroners and officials of the Health Department have been examined. The testimony presented showed that in 5,749 deaths investigated during the year 1913, necropsies were performed in only about 13 per cent. Dr. James Ewing expressed it as his opinion that this was far too small a number, and pointed out that New York got along with practically no aid from the science of legal medicine and that it was highly inadvisable to allow any one not trained in pathology to diagnose causes of death. A great deal of evidence has been presented, showing that in many instances the cause of death in the coroner's reports is very inadequately stated.

NORTH CAROLINA

Medical Legislators.—Among the members of the medical profession recently elected to the legislature are Dr. Alfred A. Kent, Lenoir and Dr. E. J. Tucker, Roxboro.

Fund for Distressed Belgians.—Dr. Samuel Westray Battle, Asheville, who was appointed by the governor, chairman of the North Carolina State Committee of Mercy to solicit aid for the distressed Belgians, has already $1,000 in hand contributed by the citizens of Asheville.

State Board Exhibit.—The State Board of Health made a creditable exhibit at the recent state fair at Raleigh. One of the attractive features of the exhibit was the analysis of a number of patent and proprietary articles, exposés of which have already been made in The Journal.

PENNSYLVANIA

The Pittsburgh Bulletin on Contagious Diseases of Children.—The October number of *The City's Health*, the monthly bulletin issued by the Pittsburgh Department of Health, is devoted especially to scarlet fever, diphtheria, measles and whooping-cough. Figures are given showing the abrupt fall in the diphtheria death-rate since the introduction of antitoxin in 1894, the rates per 100,000 population being 140 per 100,000 in the five-year period 1889-1893, 54 per 100,000 in 1894-1898 and 26 per 100,000 in 1909-1913.

Personal.—Dr. John H. Galbraith, Altoona, has been transferred from the associate staff of the Altoona Hospital to the active staff in the orthopedic department.——Dr. William A. Lynott, Scranton, has been appointed a member of the medical staff of the Federal Bureau of Mines in charge of the eye division.——Dr. Charles F. Altmiller has tendered his resignation as pathologist of the Bloomsburg Hospital.——Dr. F. McCall Keating, Philadelphia, has been appointed pathologist, and Dr. W. Wellington Woodward, West Chester, has has been made anesthetizer at the Chester County Hospital.

Philadelphia

Insanitary Conditions in Schools.—A report compiled by Dr. Walter S. Cornell, head of the medical inspection of the public schools says the sanitary condition of the public schools covering 304 buildings gives 586 specific statements of insanitary conditions.

Aid Association Election.—At the annual meeting of the Aid Association of the Philadelphia County Medical Society, November 9, the following officers were elected: president, Dr. Jacob R. Shellenberger; vice-president, Dr. James C. Wilson; secretary, Dr. Lewis H. Adler, Jr., and treasurer, Dr. John B. Turner.

The Making of a Woman Physician.—Motion pictures of the life of a woman medical student were shown for the first time at a private exhibition held at the Woman's Medical College. The pictures, entitled "The Making of a Woman Physician," recently were made at the college and consisted entirely of actual scenes, showing professors and students at their work and play. These films are to form part of the College exhibit in the Educational Building at the San Francisco Panama-Pacific World's Fair.

Personal.—Dr. Seneca Egbert, dean of the Medico-Chirurgical College, was the guest of honor at a banquet given by the first-year class of that institution at Kugler's, November 5. ——Dr. Edw. K. Tullidge, a resident of Philadelphia but attached to the Department of Charities, New York, will leave shortly for Vienna, Austria, to serve in the field hospital corps of the Austrian army.——Dr. John E. B. Buckenham has been appointed by Director Harte of the Department of Health and Charities, as superintendent of the Philadelphia Hospital for Contagious Diseases at a salary of $3,000 a year. Dr. Buckenham has been acting superintendent provisionally, succeeding Dr. William H. Walsh, who became superintendent of the Children's Hospital.——Dr. John A. Kolmer, pathologist at the Municipal Hospital for Contagious Diseases, has been appointed to the staff of that institution by Director Harte.

SOUTH CAROLINA

Sanatorium Site Selected.—The site for the State Tuberculosis Hospital has been selected at State Park. The legislature has made an appropriation of $10,000 for the institution, for which plans are being prepared.

Personal.—Dr. William Weston, Jr., Columbia, has been elected chief of staff in the new children's clinic recently opened in that city.——Dr. Thomas J. Strait, Lancaster, has resigned as senator from Lancaster County to accept the position as superintendent of the State Hospital for the Insane, Columbia.

TEXAS

Measures Against Trachoma in Schools.—A campaign against trachoma in Texas City carried on by the Mothers'-Teachers' Association began October 28, with the examination of schoolchildren. If the parents of children found to have the disease are unable to pay for treatment, the children will be given treatment at the expense of the Mothers'-Teachers' Association.

Personal.—The office of Dr. Ralph Bailey, Gatesville, was destroyed by fire, November 1, with a loss of about $2,000. ——Dr. Ernest W. Nitsche, Jr., Dallas, and Dr. Harold L. Warwick, Fort Worth, are attending the wounded in hospitals in Berlin and France, respectively.——Dr. Alva W. Carnes was pinned under his overturned automobile near Hutchins, October 8, but was only slightly injured.——Dr. Jim M. Hart, Woodbine, was thrown from his buggy in a collision with a street car, October 2, and painfully injured. ——Dr. Frederick K. Fisher, Galveston, was injured in a collision between two automobiles, September 29.——Dr. George W. Nibling, San Angelo, has been elected secretary pro tem. of the Tom Green County Medical Society, succeeding Dr. Lester C. G. Buchanan, San Angelo.

WISCONSIN

Personal.—Dr. Sidney H. Wetzler, Milwaukee, suffered severe injuries and burns when his automobile overturned in Milwaukee, November 7.——Dr. Daniel Hopkinson, Milwaukee, who suffered amputation of a toe recently, is convalescent.——Dr. Raymond C. Meyer, Elkhart Lake, has been appointed local surgeon for the Chicago, Milwaukee and St. Paul Railway.——Dr. Albert F. Schlick, Algoma, has been adjudged insane and ordered committed to the Northern State Hospital.

CANADA

Personal.—Hon. Dr. Joseph O. Reaume, Windsor, Ont., who for many years was minister of public works for Ontario, has been appointed registrar of the county of Essex. ——Drs. Herbert J. Hamilton and Edmund E. King, Toronto, have been elected to the Medical Council of Ontario for the territorial divisions of West and East Toronto, respectively. Sir James A. Grant, Ottawa, the only surviving member of the original Medical Council of Ontario, has again been reelected representative for the University of Ottawa.——Dr. Edward Worthington, surgeon to H.R.H., the Duke of Connaught, has left for England on his way to the front.

Canadian Medical Colleges.—Eighteen students have registered in the first year at the University of Alberta in the faculty of medicine. Dr. Allan C. Rankin, bacteriologist to the university, accompanied the first Canadian contingent abroad.——The number of medical students registered in the first year at Dalhousie University, Nova Scotia, is thirty-four, which is inclusive of dental students. No one has yet been appointed to the chair of pathology in this university. ——One hundred and ten freshmen have been enrolled at McGill University. The Faculty of Medicine offers to furnish the staff for a general hospital for service in the European war.——There are seventy-six freshmen in medicine at Queen's University, Kingston, Ontario. Dr. A. H. Lothrop, formerly of Columbia University, has been appointed Professor of Biological Chemistry. The faculty has offered to equip a general hospital for the front.

Hospital Notes.—The Moncton (N. B.) General Hospital has received a contribution of $1,000 from the Ladies' Aid toward the $8,000 required for completion of the proposed nurses' home of the hospital.——Thirty thousand dollars is to be expended on a new hospital at Miramichi, N. B.——A new hospital is to be built at Timmins, Ont., by the Hollinger Gold Mines Company. It will contain thirty beds.——A new wing was formally opened recently in connection with the Galt, Ont., hospital.——The Owen Sound Hospital, Ontario, is establishing a maternity ward.——The government of the province of Quebec will contribute $15,000 a year to the hospital at Maisonneuve.——The new hospital at Sherbrooke, Quebec, has been opened. It cost $88,229.——Dr. James C. Fyshe, Montreal, Que., superintendent of the Edmonton General Hospital, accompanied the first contingent to England.——Wainwright, Alberta, is to build a hospital at a cost of $10,000.——Dr. B. L. Wickware has resigned as superintendent of the Moose Jaw General Hospital, Saskatchewan. ——A hospital was recently opened at Summerland, B. C. It will accommodate about thirty-five patients.

GENERAL

Health Sermons in Richmond.—Fifteen of the pulpits of Richmond were filled November 8 by physicians in attendance at the annual meeting of the Southern Medical Association, who preached special "health sermons."

Iron Mountain Surgeons State Meeting.—The third annual meeting of the Arkansas Association of Iron Mountain Surgeons was held at Little Rock, November 17 and 18, under the presidency of Dr. Charles S. Holt, Fort Smith, Ark.

Hookworm in Panama.—The Rockefeller Hookworm Commission has established a station on the Isthmus of Panama for systematic work against hookworm which seems to prevail to a degree hitherto unsuspected. Of the first 1,000 persons examined at the laboratory, more than 700 were found to be harboring hookworm.

Executive Committee for San Francisco Session.—The Executive Committee of the Local Committee on Arrangements for the next annual session of the American Medical Association, to be held June 22-25, 1915, in San Francisco, is as follows: Dr. Herbert C. Moffitt, chairman; Dr. Solomon Hyman, secretary, and Drs. Emmet Rixford, George B. Somers, J. Henry Barbat, William P. Lucas and Philip Mills Jones, all of San Francisco.

New York and New England Surgeons Meet.—The twenty-fourth annual meeting of the New York and New England Association of Railway Surgeons was held in New York City, October 21-22, under the presidency of Dr. Clifford A. Pease, Burlington, Vt. New York City was decided on as the place for the meeting which celebrates the quarter-century anniversary of the organization of the association, and the following officers were elected: president, Dr. William H. Marcy, Buffalo, N. Y.; vice-presidents, Drs. David H. Lake, Kingston, Pa., and Halbert G. Stetson, Greenfield, Mass.; c[illegible] [illegible]etary, Dr. George Chaffee, Brooklyn; r[illegible], Dr. John H. Reid, Troy, N. Y.; and treasurer, Dr. James K. Stockwell, Oswego, N. Y.

Meetings of Railway Surgeons.—The Southern Association of Railway Surgeons held its annual meeting in connection with the meeting of the Southern Medical Association at Richmond, November 9, under the presidency of Dr. Duncan Eve, Nashville, and elected the following officers: president, Dr. Thomas H. Hancock, Atlanta; vice-president, Dr. Southgate Leigh, Norfolk, Va.; and secretary, Dr. Clarence H. Vaught, Richmond, Ky.——The twentieth annual meeting of the Big Four Railway Surgeons Association, New York Central Lines, was held in Indianapolis, November 12, and the following officers were elected: president, Dr. Isaac L. Firebaugh, Robinson, Ill.; vice-presidents, Drs. Walter M. McGaughey, Greencastle, Ind.; Clayton W. Russell, Springfield, Ohio, and John C. Sexton, Rushville, Ind.; and secretary-treasurer, Dr. Leonard A. Ensiminger, Indianapolis.

FOREIGN

Santoro Prize Given to Discoverer of Induced Pneumothorax.—For his pioneer work on treating pulmonary tuberculosis by an artificially induced pneumothorax, Professor Forlanini of the chair of clinical medicine at the University of Pavia has been awarded the Santoro prize of 10,000 lire ($2,000). This prize is given every two years by the Academy of Sciences at Rome for the most important contribution to science that has direct practical application.

The New Frankfurt University.—The issue of the *Frankfurter Zeitung* for October 25 is devoted entirely to the ceremonies connected with the inauguration of the newly founded university at Frankfurt a. M. It opens with five departments, the medical faculty having enrolled Edinger, Ehrlich, Embden, B. Fischer, Göppert, Herxheimer, Neisser, Rehn, Schwenkenbecher, Sioli, Spiess, Voss, Walthard and others to a total of twenty professors. Many of them are now at the front and there will be few students this year but the university has been duly launched. The Kaiser is said to have signed the statutes of the university on the historic date, August 1. There has long been a nucleus for a university at Frankfurt in several scientific institutes; pioneers in research and accomplishment. Chief among these is the birth-place of the side-chain theory, the Institute for Experimental Therapy and Cancer Research, of which Paul Ehrlich is director. Another is the G. Speyer Institute for Experimental Chemotherapy, where salvarsan first saw the light.

Deaths in the Profession Abroad.—F. Gerlier, aged 74, the Swiss physician who first described in 1886 what he called *vertige paralysant*, a disease attacking farm laborers and stablemen, characterized by attacks of pain, paresis, vertigo, ptosis and muscular contractions. The disease was prevalent for a time in his district but then died out. It is comparatively frequent in Japan, but rarely encountered elsewhere.——S. Engelsted of Copenhagen, at one time editor of the *Ugeskrift for Laeger*, and chief of the board of public health, aged 91.——K. Heilbronner, professor of nervous and mental disease at the University of Utrecht, succumbed to apoplexy last month, aged 44.——D. Morisani, one of the leading surgeons of Italy, professor of surgery at the University of Naples and author of numerous works on surgical subjects and of methods of suturing the intestine, fractured patella, etc., aged 65.——Our German exchanges this week add ten more names to the long list of members of the profession killed at the front. Among them is O. Loeb, privatdocent of pharmacology at the University of Göttingen; J. Diebitsch, G. Herrenschneider, Hermann, W. Kösel, W. Magnus, Paradies, Sauberzweig, Timmermann, Wertheim, H. Schultz and H. Barth of Berlin. Ten others are reported as wounded.

WAR NOTES

German Surgeons Decorated.—It is reported from Copenhagen that 118 medical officers have been decorated with the iron cross.

New Appointment.—Col. Michael W. H. Russell, R.A.M.C., has been appointed deputy director general of the Army Medical Service and temporary surgeon-general in succession to Surgeon-General W. G. Macpherson, A.M.S.

Practice of Medicine in France Opened to Belgian Physicians.—The *Medicina Contemporanea* of Lisbon states that a movement has been initiated by the members of the profession in France to throw down the barriers to the practice of medicine in that country for registered physicians from Belgium who may wish to reside in France.

Compulsory Accident Insurance for University Students.—The *Wiener klinische Wochenschrift* states that all students matriculating at the University of Vienna are required now to take out an accident insurance policy for which they pay about 13 cents (50 heller) for the semester. This is in accordance with a state decree, dated September 18, and includes all persons between 15 and 65.

Epidemic Diseases.—The *Wiener klinische Wochenschrift* of October 22, reports for the week ending October 3, 98 cases of cholera in Austria proper (9 in Vienna) and 231 in Hungary, with 11 cases in Vienna since that date. The *Berliner klinische Wochenschrift* reports 617 cases of dysentery in Prussia in the week ending October 3, and states that cholera has appeared at Kiev, and plague at Saloniki and Lisbon.

Servian Government Desires Medical Aid.—The Servian government is in immediate need of the service of qualified bacteriologists and physicians experienced in the treatment of epidemic diseases. The terms of service and remuneration will be made by arrangement. Applicants who are interested should submit their offers with references to the Secretary of the Servian Legation, 195 Queens Gate, London, S.W.

American Red Cross at Breslau.—Our German exchanges of October 20 mention the arrival at Breslau of the American Red Cross party in charge of Dr. Breadbury, accompanied by Count Talleyrand as the representative of the German Red Cross. There are twelve physicians and fifty-two nurses in the party and half of this number were distributed among the Breslau hospitals while the other half continued the journey to Vienna. Four cars with supplies for dressings, etc., were left in Breslau as the special train went on its way.

Funds Required for Physicians of Belgium.—A professional Belgium committee has been formed, consisting of Professors Stiénen and Jacobs of the University of Brussels, Professor Béco of Liége, Professor Schockaert of Louvain and Professor Benglemans, secretary of the National Therapeutic Society of Belgium, for securing immediate relief for doctors and pharmacists deprived of means of livelihood and an annuity fund for the windows and orphans of those killed in the war. Details will be arranged by a central committee in London, representing the United Kingdom.

Physicians Decorated for Bravery in the Field.—The *Wiener klinische Wochenschrift* brings each week an official list of three or four physicians whose name and regiment are thus published by the Austro-Hungarian authorities in token of appreciation for distinguished services and bravery. In addition to these the cross of Franz-Joseph order has been bestowed on Drs. J. Janak, K. Brust and A. Hocevar. The gold cross with the ribbon of the bravery medal has been given to R. Stigelbauer and R. Kaiser. Others decorated are M. Szabo, L. Redlich and R. Kraus. The iron cross has been bestowed on 120 physicians in active work with German troops at the front, including Kümmell, Rehn, Löffler, Payr, Römer, Salomon and Posner. It has also been presented to the trained nurse, Miss Scherhans, at the head of the nursing staff of the German army. She has been working on the eastern battle-line.

Wounded Soldiers and Sailors.—Between October 24 and 26 hospital ships arrived at Southampton, bringing nearly 2,000 invalid wounded troops, including a number of Belgians and Germans, who were sent to hospitals in various parts of Great Britain.——On October 26 the Hospital Ship *Oxfordshire* reached Queenstown from Boulogne, bringing twenty-six wounded officers and 700 wounded non-commissioned officers and men.——An anonymous donor has offered a fully equipped emergency naval hospital to the government, and this hospital, known as the Fourth Naval Hospital, has been erected in close proximity to the Royal Naval Hospital, South Queensferry. The buildings comprise a central administration block of eight rooms with wards radiating from the center of each side and from three of the angles.——The Second Southern General Hospital now has about 600 patients, not including the convalescent branch at Bishop's Knoll. The largest portion of the patients are composed of wounded and sick from the expeditionary force.——The Welsh Military Hospital, offered in behalf of the principality by the Prince of Wales to the War Office, has been accepted and has been located at Netley, to go overseas when required. The buildings are portable and of wood and galvanized iron, and will accommodate 104 patients in four wards pavilions. The hospital is in command of Lieut.-Col. A. W. Sheen, R.A.M.C.

Care of Wounded in Germany.—The surgeon-general of the German army, von Schjerning, published recently in a German lay paper (*Norddeutsche Allg. Zeitung*) the following report on the care of wounded and the health of the troops in the western seat of war. He commented on the difficulties inseparable from the rapid advance of the troops and the fact that at times the violence and long continuance of the artillery fire often rendered it impossible to seek the wounded on the battle-field, because "for days at a time certain points were shelled furiously. Every day many were wounded. The large battles and skirmishes over such a long extent of firing-line has made the care of the wounded extremely difficult. Surgeons and bearers had to submit to the military exigencies of the campaign, and there were many hours when it would have been madness to attempt to bring in the wounded. On the whole, however, the arrangements proved satisfactory in every way. All the wounded had their wounds bandaged on the battle-field, and this done so well that often, in fact, nearly always, the first dressing could be left unmolested until they reached the home zone. The severely wounded were brought at once to the field hospital and then to the base hospitals. As the troops were constantly pushing forward, the field hospitals had to be constantly changed and prompt transference to the base hospitals was necessary. But all was done with as little discomfort as possible. The slightly wounded were taken to the base hospitals in carts, autos or on foot; in one week there were about 40,000 to 50,000 of these, and they were all sent back to the home zone. Every train and vehicle bringing ammunition or other supplies to the front was emptied at once and sent back filled with the wounded. Only very rarely any actual hospital trains came through to the front. We had to use freight trains as we could not let the wounded accumulate for fear of bringing on epidemics. We have succeeded in avoiding this. The health of the troops is good. Catarrhal enteritis —isolated mild dysentery cases—is growing less frequent, and there are only scattered cases of typhoid.

"Of course the journey in the freight cars was not always comfortable for the wounded. But it was better to send the lightly wounded back home where they could get good shelter and care than to let them lie around in more or less demolished houses and often without adequate care. I reiterate: The transportation was satisfactory and the wounded were well taken care of at practically every station. I inspected personally 30,000 wounded at Coblentz, Liége, Namur, Sedan, Montmedy and elsewhere along the front and I did not find one who was not properly bandaged. The work on the battle-field and in the base hospitals was the hardest. Physicians and nurses worked day and night with the utmost devotion of all their energies, and I am glad to say that this was fully appreciated by the Kaiser and the military officers. The large number of iron crosses which have been bestowed on the physicians with the army testifies to the appreciation of their devoted labors. Of course some wounded man here or there did not have everything to suit him and especially the family complained at times. War nowadays takes no regard for anyone. But it would be too bad to generalize from a few scattered cases, as sometimes happens.

"There are 9,000 physicians in the field. How many are left at home, and who is adapted for service in the field and willing? Surgeons are needed in the home zone too, and as we have sent the wounded back home to be taken care of, the main task is thus placed in the hands of medical men in the home zone, so that we hope there are plenty of physicians and nurses for this task. Many nurses here at the front can find no work to do. It is utterly impossible to use them on the battle-field under present conditions of warfare and the frightful artillery fire. In one of the base hospitals I met Kraus and Pfeiffer and both confirmed my impression that the organization, the personnel and the supplies in the medical department answered all requirements, and they volunteered in addition that the work of the medical men on the firing-line was beyond all praise. As further testimony to this I mention the words of admiration for the work of the medical department spoken by the chaplain in chief for the army who has been at the front. Everywhere under the sign of the Red Cross kindly hands are ready to help and care for the wounded. We can be quite serene. The only thing that has given us trouble at times hitherto has been the transferring of the wounded from the field to the base hospital. But for this service further means of transportation have already been provided. Our Berlin autobus has proved the most useful; I took seventy-five of these along with me at the opening of the campaign. Several other cities have now sent us their park autobuses. And as now the supply of dressing materials and drugs is regularly replenished, we can be content."

LONDON LETTER

LONDON, Oct. 30, 1914.

Great Britain During the War

A visitor to this country would see nothing in the demeanor of the people to show that we are engaged in the greatest war the world has ever seen and in a life-and-death struggle to maintain our position among the nations of the earth; a war which is bringing death into many homes and into every circle in the land. The general feeling is one of calm determination to see this thing through which has been forced on us. In the streets he would notice some changes. At every turn the khaki-clad recruits are encountered and in the fashionable shops there is an unwonted quietness; but elsewhere the motto of the war, "business as usual," requires no enforcing; every one goes about his work as usual, the amount of unemployment is not abnormal, and the necessaries of life have advanced little in price. In London by night a great change would be noticed. The German dropping of bombs from aeroplanes on cities has caused great restriction of street lighting in London. The number of street lights is diminished and those which are used are covered above so that they cannot be seen from aeroplanes. Shopkeepers are not allowed to show lights which illuminate the streets. The metropolis is in semidarkness. As a result a few persons have been run over by motor cars and killed. Many of the theaters have reduced the usual evening performances to two in the week and give matinees instead. Wounded are arriving in such numbers that all the hospitals in the country, permanent and improvised, are being used for their accommodation. In three days as many as 2,000 were landed at Southampton. Over 700 wounded Irish soldiers have been landed at Cork from a hospital ship and distributed in hospitals in the South of Ireland. The War Office has accepted 247 hospitals organized by the British Red Cross, containing 8,077 beds. Free lectures are being given to the public on camp, ship and hospital hygiene, and the usual ambulance lectures have been greatly increased in number and attended by women in large numbers.

EFFECT ON THE MEDICAL PROFESSION

It has been necessary to increase the army medical corps by a large number of surgeons drawn from civil practice who enlist for the period of the war. This has created a shortage of practitioners, particularly of the young men who enter the service of institutions. As a consequence appointments usually filled by men are now offered to women physicians in greater numbers than they can take them. Another effect is a shortage of medical students at the schools, so great as to threaten a deficiency in the supply of physicians in the future. Not only have medical students gone to the front as dressers, but many have enlisted as ordinary soldiers. At Cambridge only sixty-four medical students have entered this year as compared with 116 last year. At one college noted for its medical studies thirty-two entered, but only seventeen came into residence. In order to supply the demand for army surgeons the various medical corporations have antedated their examinations this year. On the field of battle many army surgeons who have distinguished themselves by their bravery in attending to the wounded are mentioned in dispatches and some have met their death. Every number of the medical journals contain obituaries of physicians who have fallen.

THE DRUG SUPPLY

The first effect of the war was greatly to increase the price of imported drugs; but now many drugs have fallen, though the general level is still much above normal. Large shipments of many drugs have been received, and the advice issued by the government, given in a previous letter to THE JOURNAL, to avoid as far as possible prescribing drugs of which the supply was restricted, appears to have been followed. Some drugs, however, have continued to advance in price. Atropin is extremely dear and phenol (carbolic acid) is three times its normal price, because not only is it extensively used as an antiseptic, but it is also employed in the manufacture of explosives. On the other hand, some drugs are lower in price than normal. Menthol is an example for the reason that supplies which would ordinarily have gone to Germany have been diverted to English ports.

Sanitation in Training Camps

The local government board has called on the medical officers of health to cooperate with the military medical authorities regarding the insuring of satisfactory sanitary conditions for the various training camps of the home army, which at the time of writing contain over 700,000 men. The points on which special advantage from such cooperation is looked for are (1) provision of suitable water supplies and prevention of their contamination; (2) disposal of garbage and refuse; (3) drainage and conservancy, and (4) control of infectious diseases and disinfection. The good effects of this cooperation were soon manifest, and it is worthy of note that up to October 10 among 600,000 men there had been only ten cases of typhoid fever. A committee is to be formed consisting of members of the society of medical officers of health and the military medical authorities to coordinate this work.

Prize for Army Sanitation

The Chaddwick Trustees have announced that they will award the Gold Medal with a premium of £50 to the medical officers of the army and navy, respectively, who shall be adjudged, on the nomination of the Directors General of the respective services, to have achieved the most toward promoting the health of the army and navy, the military medical authorities to coordinate their work. The War Office has also lost no time in sanctioning the construction of an apparatus devised by Mr. James Menzies and Dr. Myer Copland for a system of destructive distillation of sewage, capable of providing for 12,000 men in the field.

Khaki the Usual Costume

Not only in universities "khaki's your only wear," for, besides being accepted as "academic costume" at Oxford and Cambridge, barristers have been allowed to appear in khaki in court, in place of the time-honored wig and gown on throne, that is, those who are called up in their territorial regiments and can get leave to attend to some of their professional duties.

The American Women's Hospital at Paignton

An interesting note on the American Women's Hospital, by Mr. Ernest Lane, F.R.C.S., Surgeon to St. Mary's Hospital, London, who is in charge, appears in the *St. Mary's Hospital Gazette* for October. Mr. Paris Singer placed his residence at Paignton, overlooking Torbay, on the beautiful Devon coast at the service of the American ladies, and the entire cost is sustained by Americans. It contains 200 beds with operating theatre, Roentgen-ray room and admirable lavatory and bathing accommodations. September 27, at twenty-six hours' notice, the hospital received its first batch of wounded, 130 in number, from Mons and Soissons. They landed at Southampton and went by train to Paignton, where they were transferred without a hitch, in good spirits. Most of them had not had their clothes off for two or three weeks, and had had little food, some having lain wounded in the trenches for two or three days. The cases were naturally septic for the most part, but being nearly all shrapnel wounds discharged freely from an open surface. A second batch of twenty-nine cases, mostly convalescents from Davenport, was received October 5, and a further batch of 121 October 6. The rapid recoveries made under rest, good food and skilful care is indicated by the fact that of the first 159 cases, seventy had been discharged by October 6. The executive staff of the hospital consists of Lady Arthur Paget, Mrs. John Astor, the Duchess of Marlborough, Walter Burns, Esq., Lady Randolph Churchill, Mrs. William Eustis, Mrs. Walter Burns, Lady Henry, Mrs. Hoover and Mrs. Owen.

Casualties

In no previous war have the medical casualties been so heavy. So far as I have been able to keep track, at the time of writing, and taking army and navy together, there are killed 16, wounded 18, prisoners 46, missing 14. The large number of prisoners is partly accounted for by the rear guard action of the period between the retreat from Mons and the time at which the allies assumed the offensive. Naturally in the retreat many wounded and medical officers in charge had to be left behind, and thus became prisoners.

PARIS LETTER

Paris, Oct. 29, 1914.

The Death of Dr. Emile Reymond

Dr. Emile Reymond, senator of the department of the Loire, has just met a heroic death. He was wounded while reconnoitering in an aeroplane above the German lines. He kept his head in spite of cruel suffering and, continuing to steer his machine, brought it down between the German and French lines. While being removed in the ambulance, the intrepid aviator was able to report with precision the result of the mission that he had accomplished. The commanding general gave him the cross of the Legion of Honor at his bedside.

Emile Reymond was born at Tarbes, April 9, 1865. He was the son of the great engineer, Francisque Reymond, who was director of the Ecole centrale. Emile Reymond was a laureate of the Académie des sciences, of the Faculté de médecine and of the Assistance publique. He published important surgical works, and had already acquired a reputation as a practitioner when, at the death of his father, he was elected senator. Reymond early perceived the possibility of the great development of aviation and became its ardent advocate before the senate. Aug. 29, 1910, he passed brilliantly his examination for pilot and afterward accomplished numerous flights across France, even making his electoral campaign in an aeroplane. The same year he was placed at the head of the national committee of aviation and used his greatest efforts to have the aviation branch of our army provided with 700 aeroplanes. Dr. Reymond believed that the aeroplane might be of great utility for the health service as a means of facilitating the search for the wounded on the battle-field after action and perhaps even afford rapid transportation to the ambulances.

At the time of the declaration of war, Dr. Reymond, who was a major of the first class in the military health service, insisted on being transferred to the corps of aviators and sent to the firing-line. He left with a squadron of the army of the east and his courageous conduct earned him mention in the order of the day.

The Treatment of Wounds Received in Battle

In one of the last sessions of the Société de chirurgie de Paris, several papers on this subject were read.

Dr. Paul Riche, surgeon of the hospitals of Paris, believes that it is necessary to distinguish carefully between bullet wounds, which are the only aseptic ones, and wounds from shrapnel and shell. In the case of the latter, abstention from operation must not be confused with conservation. The aim should always be conservative, but it is necessary also to operate freely and early, and when there is a gaseous septicemia to operate if the traumatic lesions compromise the future function of the member or if they do not, to make deep incisions beyond the zone infiltrated with gas. The latter point is essential.

Dr. Rochard, surgeon of the hospitals of Paris, while agreeing with Dr. Riche, emphasized the good results he has obtained with a relatively strong solution of phenol. Dr. Henri Toussaint, military physician, emphasized the advantages of early and preventive incision of wounds even in treatment at the front for wounds made by shrapnel or fragments of shell. When once a sufficient channel of exit has been opened to the products of infection, it is necessary to refrain absolutely from attempting to close the wound either by suture or by clips. Toussaint has observed two cases in which clips appear to have caused phlegmonous complications which improved after the removal of the clips and drainage of the wounds.

As for puncture, Dr. Picqué believes that it is necessary to distinguish between septic and aseptic wounds, of which the first only should be incised.

The Transportation of the Wounded

Since the beginning of the war, the government has been trying to improve the transportation of the wounded and has taken up with the railway companies the creation of sanitary trains. The companies have organized a certain number of sanitary trains, composed in part of freight-cars, arranged to permit the transportation of the wounded on litters and in part of cars arranged for the wounded who were able to travel seated. Nine wounded men may be transported in a freight car and forty may travel in a car arranged for those who can travel seated. Altogether these trains can transport 70,000 wounded. The minister of public health is, moreover, studying at present, means of using boats and of removing soldiers from the field of battle by canals, rivers and smaller streams. Forty-four wounded men, with all the medical staff and supplies needed, may be transported on a boat. While transportation by water is slow, it is accomplished without shock, and under such conditions that the wounded may be treated as if in a hospital.

Aid for Belgian Students

At its last session, the council of the Université de Paris unanimously resolved that Belgian students who before the war had been matriculated in one of the universities of their own country might become matriculated in the schools of the Université de Paris without having to pay the matriculation, inscription and library fees. Young Belgians from the Belgian establishments of secondary education will likewise be received if they fulfil the conditions exacted by the Belgian universities. In default of diplomas and certificates, the young people may prove their qualifications by such means as are possible, for instance, certificates of French or Belgian diplomatic or consular agents.

Localities Without Physicians and Physicians Without Patients

Many communes in the vicinity of Paris and in the departments have been left without physicians by the mobilization. Also the invasion of the north and northeast of France has driven out a certain number of physicians who are deprived of all resources and all patients. The Société médicale des hôpitaux de Paris has therefore requested of the dean of the Faculté de médecine to constitute himself a receiving center for the requests from communes for physicians and for the applications of physicians without practice.

Marriages

Frederick Elmer Munch, M.D., Chicago, to Miss Alma B. Kundert of Racine, Wis., at Martintown, Wis., October 28.

Frank Samuel Child, Jr., M.D., to Miss Helen Horton Bayles, both of Port Jefferson, L. I., N. Y., October 22.

Victor Eugene Kaufman, M.D., Canton, Ohio, to Miss Ella Lucille Moody of Carrollton, Ohio, October 20.

Frank Joseph Sykora, M.D., Brainerd, Minn., to Miss Adelaide Stoll of Little Falls, Minn., October 27.

Frank Burton Stephenson, M.D., Indiana, Pa., to Miss Elizabeth H. Wood of Philadelphia, October 28.

Howard Albert Hamilton, M.D., Drynob, Mo., to Miss Lois Brown of Springfield, Mo., October 11.

Hugh Owen Williams, M.D., Balaton, Minn., to Miss Ada E. Chrysler of Granville, Ohio, October 15.

John Graham Davis, M.D., Lincoln, Neb., to Miss Lenore Barber of West Pittston, Pa., October 22.

Karl Brooks Sturgis, M.D., Augusta, Me., to Miss Alice W. Fiske of Rockland, Me., October 28.

Firmadge King Nichols, M.D., to Miss Helen Marienne Spangler, both of Baltimore, October 24.

Morris Braude, M.D., Chicago, to Miss Dorothy Rosenstein of Mishawaka, Ind., recently.

William Frederick Becker, M.D., to Mrs. Becker, both of Chicago, October 27.

Deaths

Joseph Scribner Gibb, M.D. University of Pennsylvania, Philadelphia, 1880; a Fellow of the American Medical Association and College of Physicians of Philadelphia; from 1882 to 1892 outdoor physician to the Philadelphia Department of Charities and Corrections, and surgeon to the police department; from 1881 to 1884 in charge of the nose, throat and ear department of the Northern Dispensary; since 1893 professor and emeritus professor of diseases of the throat and nose of the Philadelphia Polyclinic; laryngologist to the Episcopal Hospital; who was seized with a cerebral hemorrhage at the Overbrook Golf Club, November 6; died at his home in Philadelphia, November 7, aged 55.

James Bartlett Brewster, M.D. Bellevue Hospital Medical College, 1866; a member of the Massachusetts Medical Society and formerly state medical examiner; surgeon of the Forty-Fourth Massachusetts Volunteer Infantry and assistant surgeon of the Second Division, Ninth Army Corps, during the Civil War, and surgeon-general of the Department of Massachusetts of the Grand Army of the Republic; at one time acting assistant surgeon in the United States Public Health and Marine Hospital Service; died at his home in Phillips, Mass., November 7, aged 73.

Osmon Beverly Campbell, M.D. Northwestern Medical College, St. Joseph, Mo., 1881; Jefferson Medical College, 1884; a Fellow of the American Medical Association; formerly president of the Tri-State Medical Society of Iowa, Illinois and Missouri; Western Gynecological and Surgical Association and Medical Society of the Missouri Valley; widely known as a surgeon of St. Joseph, Mo.; dean of the Central Medical College and professor of gynecology and abdominal surgery; died in his home in St. Joseph, November 11, after an illness of two years, aged 54.

George Livingston Peabody, M.D. College of Physicians and Surgeons in the City of New York, 1873; later professor of materia medica and therapeutics in his Alma Mater and from 1884 to 1887 a trustee and member of the council of Columbia University; formerly attending physician to New York Hospital, and consulting physician to the Roosevelt Hospital, New York City; died at his home in Newport, R. I., October 30, from heart disease, aged 64.

George Stanley Lynde, M.D. College of Physicians and Surgeons in the City of New York, 1866; a member of the Medical Society of the State of New York, New York Academy of Medicine and New York Pathological Society; for more than twenty-five years a member of the New York Board of Health and from 1907 to 1912 chief diagnostician of the board; died in the New York Hospital, November 5, after a surgical operation, aged 53.

Walter D. Green, M.D. University of Pennsylvania, Philadelphia, 1886; resident physician at the Presbyterian and Pennsylvania hospitals until 1892; then for two years medical inspector of the Philadelphia Bureau of Health, and in 1894 port physician of Philadelphia; aged 53; while a patient at a sanatorium in Bellemeda, N. J., October 25, wandered to the tracks of the Philadelphia and Reading Railroad and was struck and killed by a train.

Sarah R. Munro, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1872; a member of the Wisconsin State Medical Society; for many years a practitioner of Milwaukee; visiting physician to the House of Mercy and a director of the House and Home Farm School for Boys at Dousman, Wis.; died at her home in Milwaukee, November 3, aged 74.

Herman Reeve Ainsworth, M.D. New York University, New York City, 1866; a member of the Medical Society of the State of New York and its vice-president from 1905 to 1907; president of the Steuben County Medical Society in 1874; a member of the American Association for the Advancement of Science; died at his home in Addison, N. Y., September 3, aged 73.

Henry Northam Bryan, M.D. Jefferson Medical College, 1884; Medico-Chirurgical College of Philadelphia, 1895; a Fellow of the American Medical Association, and a member of the Medical Club of Philadelphia; for eleven years head of the surgical staff of the Medico-Chirurgical Hospital; died at his home in Philadelphia, November 2, aged 61.

John Ernest Gould, M.D. Western Pennsylvania Medical College, Pittsburgh, 1895; a member of the Medical Society of the State of Pennsylvania; died at his home in Pittsburgh, October 28, aged 44.

Albert Gallatin Jones, M.D. St. Louis Medical College, 1855; Chicago Medical College, 1860; for twenty-five years a practitioner of Milton, Ill., since that time a farmer near Kingston, Mo., and for the last four years a resident of Hamilton, Mo., and president of the Farmers' and Merchants' Bank in that city; died at his home, August 10, from arteriosclerosis, aged 81.

James Taylor Woodburn, M.D. Louisville (Ky.) Medical College, 1876; a member of the Kentucky State Medical Association; for twenty years a member of the board of health of Muhlenberg County, Ky.; and from 1910 to 1914 mayor of Central City, Ky.; died at his home in Central City, November 2, from nephritis, aged 64.

Ira F. Hart, M.D. Jefferson Medical College, 1852; formerly a member of the American Medical Association; a surgeon of Volunteers throughout the Civil War; editor of the *Saturday Evening Review* and of the *Elmira Advertiser* for many years; died at his home in Elmira, N. Y., October 30, from senile debility, aged 84.

Leo O. Egginton, M.D. Western Pennsylvania Medical College, Pittsburgh, 1907; formerly pathologist to the Independence (Iowa) State Hospital; died at his home in Juneau, Alaska, October 21, from appendicitis, aged 32.

James Jerome Hassett, M.D. Rush Medical College, Chicago, 1890; a member of the Illinois State Medical Society and of the Illinois State Board of Health; died at his home in McLeansboro, Ill., October 28.

Amos Jesse Newell, M.D. Rush Medical College, 1892; formerly a member of the American Medical Association; of West Pullman, Chicago; died in the Meadville, Pa., City Hospital, about October 21, aged 59.

Malcolm Duane Lewis, M.D. University of Missouri, Columbia, 1875; a member of the Missouri State Medical Association; died in his office in Columbia, Mo., October 22, from cerebral hemorrhage, aged 68.

James W. Money, M.D. University of Louisville, Ky., 1874; a pioneer practitioner of Central Kansas; died at his home in Herington, Kan., about October 14, from cerebral hemorrhage, aged 65.

William Ivan Senkler, M.D. University of Toronto, Ont., 1891; L.R.C.P. and L.R.C.S. Edinburgh and L.F.P.S. Glasgow, 1892; died at his home in Vancouver, B. C., July 29, aged 46.

William Henry Downey, M.D. Harvard Medical School, Boston, 1898; a member of the Massachusetts Medical Society; died at his home in Taunton, Mass., October 1, aged 49.

Blythe Jackson Callantine, M.D. Rush Medical College, 1913; after his graduation an intern in St. Luke's Hospital, Chicago; died at his home in Clifton, Ariz., October 28, aged 29.

Ely Bradley, M.D. University of Pennsylvania, Philadelphia, 1857; a member of the Medical Association of the State of Alabama; died recently at his home in Belleville, Ala., aged 78.

J. Franklin Barnes, M.D. Bellevue Hospital Medical College, 1875; a member of the Schuyler County (N. Y.) Medical Society; died at his home in Watkins, N. Y., about October 29.

Edward F. Gifford, M.D. Cleveland Medical College, 1893; of Erie, Pa.; died in the Hamot Hospital in that city, October 23, from septicemia due to an operation wound, aged 48.

Joseph Foster Dorsey, M.D. Starling Medical College, Columbus, Ohio, 1870; died at his home in Dresden, Ohio, October 22, from cerebral hemorrhage, aged 79.

William Garrett Stone, M.D. Vanderbilt University, Nashville, Tenn., 1879; formerly of Columbus, Ohio; died at Greenwood, Miss., about October 15, aged 59.

Adam Lindsey Wright Webb, M.D. University of Toronto, Ont., 1903; of Brighton, Ont.; died September 11, from accidental poisoning by toadstools, aged 35.

Daniel J. Reeder, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, Ga., 1882; died at his home in Atlanta, October 24, aged 58.

Archibald C. Leslie, M.D. McGill University, Montreal 1890; of Kathryn, N. Dak.; died at McVille, N. Dak., about October 23, aged 54.

James Weir Renwick, M.D. University of Toronto, Ont., 1875; died at his home in Courtland, Ont., July 3, aged 67.

John L. Fitzporter, M.D. Washington University, St. Louis, 1871; died at his home in St. Louis, October 23.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

ARTICLES REFUSED RECOGNITION

(*Continued from page 1778*)

Reports of the Council on Pharmacy and Chemistry

[The abstracts that follow deal with articles which, having been refused recognition, were not deemed of sufficient importance to require lengthy reports. A previous instalment of abstracts appeared in THE JOURNAL, Nov. 14, 1914.]

Lysoform and Lysoform Crude

Lysoform, made by the Lysoform Gesellschaft, Berlin, Germany, according to the information submitted, is a watery solution of potash-soap containing 6-7 per cent. of formaldehyde. Crude Lysoform is said to contain 10 per cent. of formaldehyde and to be made from cheaper oils, such as linseed oil.

Examination showed that the name "Lysoform" was blown in the glass and that a circular was wrapped around the trade package which recommended its use in conditions such as the following: "bites," "furunculosis," "softening abscesses," "insect-bites," "chronic and acute catarrhs" and "catarrh in the throat." The name was blown in the glass of the sample package of Crude Lysoform and the following claims appeared on the label:

> "Eingeführt in den Heilstätten zur Bekämpfung der Tuberkulose."[1]
>
> "Bestes Mittel zur Verhinderung und Beseitigung von Tierseuchen aller Art bei Pferden, Rindvieh, Schweinen, Schafen, Katzen, Hunden u. Geflügel."[2]

The referee recommended that these objections, constituting conflicts with the rules of the Council, be brought to the attention of the Lysoform Gesellschaft, and also that evidence be requested for the assertion made that soap is efficient as a means of removing the local effects of formaldehyde, and for Lysoform's asserted "thorough efficiency as a powerful disinfectant." The referee pointed out that the papers of Pfuhl (*Hygienic Review*, 1902-3), Symanski (*Jour. Hyg. and Infect. Dis.*, 1901-3) and Seydewitz (*Centralbl. f. Bacteriol.*, 1902-3) used in the advertising circular for Lysoform really show that Lysoform possesses only a moderate germicidal action and that the claim that Lysoform is a powerful disinfectant is misleading, especially in view of the work of Seydewitz (1902) who states that it requires a longer time of action than other disinfecting agents.

The referee's report having been adopted by the Council it was sent to the manufacturer Dec. 19, 1913. No action having been taken to remove the reported conflicts with the rules or to present evidence to substantiate the claims made, the Council voted that Lysoform and Crude Lysoform be refused recognition.

Phecolates, Phecolax, Phecozymes and Phecotones

Phecolates, Phecolax, Phecozymes and Phecotones were submitted by F. Waldo Whitney, New York, with "literature" indicating that they are designed to form parts of a system of treatment founded on the theory of autotoxemia, which they are supposed to prevent by their action on the functions of the intestinal canal. The different preparations consist in the main of mixtures of well-known remedies. The basic preparation is Phecolates, which contains bile salts in combination with phenyl salicylates and benzo-naphthol in about one-eighth the regular doses and hence not likely to be of any real service. Since the proportions of these ingredients ought to be regulated by the physician according to the needs of the individual patient, they should not be combined in fixed proportions. The name is not so framed as to indicate the principal ingredients.

Phecolax contains, in addition to the ingredients of Phecolates, phenolphthalein and cascarin, of each one-half grain.

Phecozyme is made more complex than Phecolax by the introduction of additional phenyl salicylate and of pancreatin. Phecotone contains ten ingredients.

Extravagant claims such as the following are made:

> "Our Health is governed by our bowels; Our bowels are governed by our nerves; Our nerves are governed by our digestion; our digestion is governed by Phecolates."

The Council voted to refuse recognition to Phecolates, Phecolax, Phecozymes and Phecotones as unscientific articles with objectionable names.

Serum Vaccine, Bruschettini

The Serum Vaccine, Bruschettini, sold by R. G. Berlingieri, New York, has for its aim the destruction of the tuberculous cell and the facilitation of its elimination by the natural expulsion process, it being held that this constitutes a victory in the struggle against consumption as much as obtaining the death and elimination of the specific bacillus. The description for the preparation of this "Serum Vaccine" is complicated and makes the impression that it is based on a number of unproved hypotheses.

After an examination of the evidence submitted the Committee on Serums and Vaccines recommended to the Council that further consideration be postponed until the manufacturer submit proof of the value of the preparation. The Council having agreed to the recommendation, this action was communicated to the American agent for Serum Vaccine, Bruschettini, June 14, 1913. After waiting nearly a year for evidence to substantiate the claims made for the product the Council voted that Serum Vaccine, Bruschettini, be refused recognition. This action having been communicated to the manufacturer, the information was received September, 1914, that the Serum Vaccine is now used only in slight cases.

Sherman's Non-Virulent Tubercle Vaccine

Consideration of this product of G. H. Sherman, Detroit, having been requested, the Committee on Serums and Vaccines examined the information and advertising matter submitted. It then recommended that in view of the far-reaching claims made for this preparation, for example, that "comparatively small doses of the killed organism will produce a marked immunizing response to the virulent human tubercle bacillus," that consideration be postponed, and the manufacturer be requested to submit evidence—reports of animal experimentation and case reports—to substantiate his claims. After waiting more than six months for the required evidence, the Council voted that Sherman's Non-Virulent Tubercle Vaccine be refused recognition.

White Sulphur Salts

White Sulphur Salts, put on the market by the White Sulphur Springs, Inc., White Sulphur Springs, W. Va., is said to be an effervescing salt containing sodium phosphate, magnesium sulphate, sodium sulphate, and sodium citrate with an effervescing base consisting of sodium bicarbonate, citric and tartaric acids and saccharin. It is claimed that one teaspoonful of the mixture represents "the approximate equivalent of one glass of the White Sulphur Spring Water." Comparison showed that the composition of White Sulphur Salts as claimed did not agree with the submitted analysis of White Sulphur Spring Water, the spring water containing calcium, strontium, iron, manganese, lithium, silica and alumina, which were not present in the artificial salts. Further, one teaspoonful of the manufactured sulphur salts to a glass of water would contain from 50 to 75 grains of the several salts, whereas the White Sulphur Spring Water would contain approximately 8 grains of the several salts. White Sulphur Salts being neither an artificial form nor an approximate equivalent of White Sulphur Spring Water, the Council held it not eligible for inclusion with N. N. R. or the appendix.

Unguentum Selenio Vanadic (v. Roemer)

Unguentum Selenio Vanadic (v. Roemer) is an ointment manufactured by A. von Roemer, Brooklyn, N. Y., and put on the market by Schering and Glatz, New York. It is claimed to contain 1 per cent. of selenium oxycyanid and 1 per cent. of vanadium chlorid "so prepared and incorporated into a modified lanolin base as to insure complete absorption." The preparation is recommended in the later stages of inoperable carcinoma, sarcoma, epithelioma and other malignant tumors, as a substitute for morphin and other narcotics to control pain, as a modifying (ante-operative) treatment in the middle stage of malignant cases presenting the characteristics of being inoperable, and as a prophylactic treatment of recurrences and metastases following excision of malignant tumors. It is also recommended for use in slow-healing surgical wounds, abscesses, tuberculous and mixed septic and gangrenous processes, etc., in lupus, acne, eczema, psoriasis, scabies, erythemata, adenomata, angiomata, papillomata, etc. The use of the ointment is further recommended by systemic inunction in septicemia, pneumonia, erysipelas, cerebrospinal meningitis, septic rheumatism, septic neuritis, etc. The Council voted that the preparation be not accepted for inclusion with New and Nonofficial Remedies because no evidence has been submitted that the vanadium and selenium are absorbed or that they produce any of the effects claimed.

---

[1] Introduced into sanatoriums for the treatment of tuberculosis.

[2] Best means for the prevention and suppression of epidemics among horses, cattle, swine, sheep, cats, dogs and poultry.

When the preceding report was sent to Schering and Glatz, the firm expressed surprise that evidence of the absorption of selenium and vanadium should be requested. On June 8 the firm wrote that within a few days one or more tests would be sent by which the presence of selenium and vanadium in the urine could be demonstrated. These tests were not received. So far (November, 1914) no evidence of the value of the preparation either in carcinoma or in any of the very long list of other diseases in which it is recommended has been submitted, and, the pharmacologic evidence that such a preparation would be of value in such conditions being practically nil, the Council authorized publication of this report.

(To be continued)

IODIA

Report of the Council on Pharmacy and Chemistry

The following report on Iodia was adopted by the Council and its publication authorized.

W. A. PUCKNER, Secretary.

Iodia is put on the market by Battle and Company, under the claim that it contains potassium iodid in combination with iron phosphate and vegetable "principles." It is ext. vagantly recommended for use in many and varied conditions. For instance, it is "an unexcelled altero-reconstructive," "almost a specific" in eczema and rheumatism and "a highly efficient form of iodin," which will not produce iodism!

The therapeutic effects of iodids result from a chemical transformation by which molecular iodin is set free in the tissues, thus producing a mild degree of iodism. It follows, then, that a preparation which cannot give rise to the symptoms of iodism cannot be expected to produce the therapeutic effects of the iodids. The claim that Iodia is *therapeutically* efficient without producing iodism therefore justifies suspicion, to put it mildly.

In view of the exaggerated tone of the advertising, together with the fact that a report from the Chemical Laboratory of the American Medical Association showed marked discrepancies between the formula and the *composition* of Iodia, it seemed desirable to investigate this product. The report of the laboratory, which is given below, shows conflict with Rule 1 (secrecy of composition) and with Rule 2 (false claims of standardization). A discussion of the claims made for Iodia follows the report.

LABORATORY REPORT

The composition of Iodia is given thus:

> "Formula.—Iodia is a combination of active principles obtained from the green roots of Stillingia, Helonias, Saxifraga, Menispermum and aromatics. Each *fluid drachm* also contains two and one-half grains Iod.-Potas. and one and one-half grains Phos.-Iron."

We are told that:

> "Its several ingredients are selected with *scrupulous* care, and the most exacting methods are constantly employed to insure absolute uniformity and maximum therapeutic potency."

This "formula" is an absurdity: First, the amounts of the "active principles" of the plants named are not given; second, these "principles," with the possible exception of menispermum alkaloids, have not been isolated; and, third, ferric phosphate and potassium iodid are incompatible! Incidentally, there are no methods whereby it is possible to secure "absolute uniformity" of a mixture such as Iodia is claimed to be.

Qualitative tests demonstrated the absence of iron and the absence of all but traces of phosphorus compounds (0.015 gm. phosphorus per 100 c.c.). Minute traces of alkaloids, possibly from menispermum, were found (*that* amount being about 0.004 gm. per hundred c.c. of the preparation). Therapeutically this quantity is entirely negligible. Determinations of iodid demonstrated the presence of only about 60 per cent. of the amount of potassium iodid claimed. The "formula" for Iodia is false and misleading.[1]

DANGEROUS RECOMMENDATIONS

One of the Iodia labels reads:

> "INDICATIONS.—Syphilitic, scrofulous and cutaneous diseases, dysmenorrhea, menorrhagia, leucorrhea, amenorrhea, impaired vitality, habitual abortion and general uterine debility."

Such recommendations are likely to lead to self-drugging in conditions that are not only dangerous to the individual but also a menace to the community. The preparation thus conflicts with Rule 4 of the Council. After admitting the need of efficient iodid medication in certain stages of syphilis and after exaggerating the frequence and severity of symptoms of iodism, an advertising circular entitled "Practical Therapeutics" asserts:

> "Iodia then is the preparation of iodid of potassium to be preferred whenever it requires to be administered in large doses or for prolonged periods of time . . .
>
> "Not only does the association of the iodid of potassium with the vegetable alteratives offer a measure of protection against iodism but the latter exert depurative effects on their own account . . ."

It is generally accepted that in certain stages of syphilis the only hope of success lies in efficient iodin medication. The exploiters of Iodia state that a dose of the nostrum contains 2½ grains of potassium iodid; actually it contains only 1½ grains. To urge physicians and the public to depend on this product for efficient iodid medication constitutes an unwarranted therapeutic exaggeration (Rule 6) which approaches criminality. The reason Iodia does not produce iodism is that, in the doses recommended, the iodin action is extremely feeble.

Likening the human body to a factory and discussing the "break downs" which are likely to occur, a circular entitled "Always Trustworthy" says:

> "When administered in proper dosage, Iodia stimulates organic functions, promotes the elimination of waste products, and re-establishes metabolic activity. It increases the solvent properties of the blood, and arrests abnormal tissue metamorphosis. In other words, it lends material assistance to weakened cells and curbs those unduly active. Iodia, obviously, has a wide range of indications. It has been most generally and successfully employed, however, in Syphilitic, Scrofulous and Cutaneous Diseases, Rheumatic and Gouty Ailments, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortion and General Uterine Debility, and wherever a reliable altero-reconstructive is required."

These recommendations show that in addition to the objections already given, this nostrum is an *unscientific shotgun mixture*. This brings it in conflict with Rule 10 (unscientific articles inimical to the medical profession and the public).

It is recommended that Iodia be refused recognition.

Correspondence

Priority in Discovery of Drainage Apparatus

To the Editor:—In THE JOURNAL, Nov. 7, 1914, p. 1667, I observe an article by Dr. Lucian W. Smith of Lafayette, Ind., on "Suprapubic Prostatectomy with Special Reference to Drainage."

As to the drainage apparatus which is the point of the article: A reference to the *Annals of Surgery* for April, 1896, also for October, 1899, will show the same thing described *in* full as my invention. Or rather, I credited the principle—though far less simply carried out—to Dr. Snow, a dentist of Buffalo, who first employed it many years *earlier;* and ever since then dentists everywhere have made use of it to empty of saliva the sublingual space during dental operations.

In the *Annals* articles quoted my device will be found also employed for estimating the amount of urine passed and for washing out the bladder.

---

[1] It should be noted that the discrepancies here reported between the actual and the claimed composition of Iodia were pointed out more than thirty years ago by A. B. Lyons (Detroit *Lancet,* October, 1882, vi, 157-8), who found that *Iodia* was deficient in iodid content and practically free from iron.

To quote from only one author, where if desired several could be cited, on page 416 of Dr. G. E. Brewer's work on surgery the same device is illustrated for his article on suprapubic cystotomy, and is credited to me

I have no doubt that Dr. Smith thought of this quite independently, and is simply unfortunate in that another writer happened to be born earlier. Indeed, so simple and at the same time practical and efficient is this mode of draining any cavity from its top instead of its bottom that the wonder is that this idea is not reborn yearly!

Let me remark, in conclusion, that I make the necessary loop in the exit tube from the reservoir by tying a simple knot in this tube. This makes it self-retaining. And the smaller the loop and the nearer down toward the floor it is placed, the better does the apparatus work. The Y-connection entering from the tube to the bladder should join as closely above the loop aforesaid as it conveniently can.

A valve at the lower end of the exit tube is not necessary. Any little weight, such as a door-key or a pebble fastened to the tube-end, holding it under water, is alone needed.

Robert H. M. Dawbarn, M.D., New York.

Alphonso Corti Correspondence

To the Editor:—Apropos of your interesting account of Marquis Alphonso Corti (The Journal, Nov. 7, 1914, p. 1676), I enclose a letter on file in the correspondence of the late Prof. Joseph Leidy which may interest your readers. Some years ago on a visit to Milan and Turin I got in touch with members of his family now living in Milan. I had hoped to obtain Professor Leidy's replies to the Corti correspondence. Though I understand some of his correspondence was preserved, there was unfortunately nothing of scientific interest.

Joseph Leidy, M.D., Philadelphia.

Turin, August 1, 1852.

My Dear Sir:—Having seen from your interesting observations on the microscopic structure of cartilage that you occupy yourself with microscopic anatomy—I am not aware of any one else doing so in America, I avail myself of the very kind offer of Mrs. White, returning home from here, to send you a copy of the first part of my research on the organ of hearing of mammalia. I was obliged to make my studies principally on domestic animals because it is very difficult in Europe to obtain wild animals, which will be easier for you in America. As you will see that my discoveries on that subject are not without interest to physiology—I wish I might induce you to repeat my observations and extend them over a larger number of wild animals.

I should be very happy to keep up a scientific correspondence with you on physiology and microscopic anatomy. I am at the beginning of my scientific career, and I will direct all my endeavors to the physiological anatomy of animals.

My already long letter will perhaps have annoyed you. Excuse me for it; but science and more than any other the study of nature brings men near to each other and will probably later bring me on a visit to your native country, the most wonderful both for its political institutions and for its natural productions.

You will greatly oblige me with an answer [and], believe me, My dear sir,

Your obedient servant,

Alphonso Corti,
at Turin, Kingdom of Sardinia.

I enclose two short German articles of mine and two Italian ones of my friend Dr. d. Filippi, Professor of Zoology and Director of the Zool. Mus. here.

To Dr. Joseph Leidy,
Philadelphia Academy of Sciences.

The Neglect of Vital Statistics.—If the unborn historian of hygiene in the twentieth century shall find one anomaly more curious than any other, it will be that the twentieth century, opening with prodigious resources immediately available, ran a third or half its course before these resources became so standardized that each unit of power might be accounted for in a definite scheme of vital statistics.—J. S. Fulton.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SEWER AND WATER PIPES IN THE SAME TRENCH

To the Editor:—In a town where it is exceedingly expensive to dig ditches owing to the rocky formation, would it be advisable or objectionable to lay the sewer pipe and the water pipe in the same ditch?

Charles W. Sult, M.D., Flagstaff, Ariz.

Answer.—The proximity of sewer pipes and water pipes is not altogether free from objection, but if the water pressure is constant and the sewer pipe is laid with tight joints there will probably be little risk under ordinary conditions. Careful construction should obviously be insisted on to reduce so far as possible the likelihood of an "accident."

ARTICLES ON ABDERHALDEN'S METHOD

To the Editor:—Can you refer me to any articles treating of the diagnosis of disease by means of Abderhalden's serum reaction?

J. D. Blything, M.D., Bettendorf, Iowa.

Answer.—A list of articles on the serodiagnosis of pregnancy was published in The Journal, Oct. 12, 1912. In the issue of September 6, p. 788, the technic was described and a full list of references was given; Dec. 6, 1913, p. 2087, a list of references to articles appears; and May 16, 1914, p. 1576, a list of references to the use of the test in psychiatry, together with a description of the technic, was published.

CEDAR POISONING—SOFTENING HARD WATER

To the Editor:—1. Lumber mill men frequently consult me for "cedar poisoning" on their hands. Is there such an ailment? If so, please give etiology, treatment and differential diagnosis from eczema and syphilis. I was of the impression that oil of cedar was soothing and mildly antiseptic.

2. Give a method of rendering hard water soft other than by boiling. This question was asked in a medical examination. The inhabitants of Kansas let the water freeze and then melt the ice. The result is soft water. Will you please explain why this is true? L. H.

Answer.—1. There are a large number of substances which produce irritation of the skin known as dermatitis venenata. The lists of these substances given in the works on dermatology are not complete but they do not include cedar. The diagnosis of such an affection would be most easily made by noting the recovery on removal of the supposed cause and the recurrence on renewed exposure. The diagnosis of eczema would be made by comparing the characters of that disease, which would probably persist after the cedar oil was removed.

2. Hard water can be softened by mixing it with a definite quantity of milk of lime which converts the carbonic acid into calcium carbonate and causes the precipitation of the calcium carbonate originally present in the water. When water freezes, the salts present in it are left behind so that the ice is very nearly pure water.

NARCOPHIN

To the Editor:—Can you give me any data concerning Narcophin advised by Prof. Krönig as an anesthetic in obstetrics? I understand it is a proprietary double salt of morphin and narcotin but have no record of its percentage composition.

C. E. Dakin, M.D., Mason City, Iowa.

Answer.—The manufacturers state that Narcophin is a double salt consisting of morphin meconate and narcotin meconate in molecular proportions, containing about 30 per cent. of morphin alkaloid. They claim that it is a scientific substitute for opium and that it has advantages over morphin; specifically that it is much less liable to produce respiratory disturbance or nausea. Examination made in the A. M. A. Chemical Laboratory essentially verified the claims made in regard to the composition of Narcophin (*Reports of the A. M. A. Chemical Laboratory,* 1913, vi, 92). The Council on Pharmacy and Chemistry, however, was unable to accept the therapeutic claims made for the preparation and voted not to accept it for inclusion in New and Nonofficial Remedies.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, Jan. 5, 1915. Chairman, Dr. W. H. Sanders, Montgomery.
California: Los Angeles, December 8. Sec., Dr. Charles B. Pinkham, 727 Butler Bldg., San Francisco.
Delaware: Dover and Wilmington, December 8-10. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.
Florida: Palatka, December 2-3. Sec., Dr. E. W. Warren, 102 Front St., Palatka.
Kentucky: Louisville, December 16-18. Sec., Dr. A. T. McCormack, Bowling Green.
Maryland: Baltimore, December 8. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown. Homeopathic, Baltimore, December 15-16. Sec., Dr. O. N. Duvall, 1817 N. Fulton, Baltimore.
Missouri: St. Louis, December 14-16. Sec., Dr. J. A. B. Adcock, State House, Jefferson City.
New Hampshire: Concord, December 29-30. Regent, Mr. H. C. Morrison, Concord.
Ohio: Columbus, December 8-10. Sec., Dr. George H. Matson.
Pennsylvania: Philadelphia, December 1-3. Sec., Dr. N. C. Schaeffer, Harrisburg.
Virginia: Richmond, December 15-18. Sec., Dr. J. N. Barney, Fredericksburg.

Higher Preliminary Requirements in Louisiana

A letter from Dr. E. L. Leckert, secretary of the Louisiana State Board of Medical Examiners, states that at the meeting of that board held October 29, a resolution was adopted that all students matriculating on and after June 1, 1915, in addition to a standard four-year high-school education, must present evidence of the successful completion, at an approved college or university, of one full year of work in biology, physics, chemistry and a modern language. This will apply to all applicants seeking licenses in Louisiana who graduate in 1919 and thereafter. This is the twenty-third state which has adopted the requirement of one or more years of collegiate work as the minimum standard of preliminary education.

Delaware Regular and Homeopathic Report

Dr. H. W. Briggs, secretary of the Medical Council of Delaware, reports the written examination held at Dover and Wilmington, July 16-18, 1914. The total number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 11, all of whom passed. Three candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Baltimore Medical College	(1913)	80.4, 83
University of Maryland	(1911)	82.4
New York Homeo. Med. Coll. and Flower Hosp.	(1913)	91.5
Hahnemann Medical College and Hosp., Philadelphia	(1914)	92.4
Jefferson Medical College	(1914)	84.1, 87.7
Medico-Chirurgical College of Philadelphia	(1914)	81.4, 81.5, 87.7
University of Pennsylvania	(1914)	87.1

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
George Washington University	(1906)	Maryland
Medico-Chirurgical College of Philadelphia	(1912)	Penna.
University of Pennsylvania	(1907)	New Jersey

Arkansas Eclectic May Report

Dr. C. E. Laws, secretary of the Arkansas Eclectic Medical Board, reports the oral and written examination held at Little Rock, May 12-13, 1914. The total number of subjects examined in was 12; total number of questions asked, 120; percentage required to pass, 75. The total number of candidates examined was 16, all of whom passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Georgia College of Eclectic Medicine and Surgery	(1914)	93.8
American Medical College	(1912)	82.2
Eclectic Medical University, Kansas City	(1901) (1914)	83.8 75, 76.2, 77.7, 79.1, 80.2, 82, 84, 85, 86.6.

Book Notices

Die Entstehung und Behandlung der Karzinome. Von Hofrat Dr. A. Theilhaber. Paper. Price, 8.20 marks. Pp., 182, with 17 illustrations. Berlin: S. Karger, 1914.

In the opening paragraph the author says that the statement commonly made that practically nothing is known concerning the cause of carcinoma is too pessimistic, and he declares that more is known to-day about the cause of carcinoma than is known about the cause of the majority of other diseases. He then takes up the causes of carcinoma under two headings: (1) local and (2) humoral. Under the first he mentions the usual headings: local irritation, chronic inflammation, trauma, scars, parasites (non-specific), etc., but brings out nothing new. Under the second are mentioned the influence of race and of social position, heredity, character of the food and of the soil, psychic excitement or depression, the structure and function of the internal organs, etc. After reading all the author has to say concerning the numerous causes of carcinoma one cannot fail to be impressed with the fact that the evidence in favor of each and all of them is insufficient. Under treatment considerable space is devoted to the use of the Roentgen ray. The author thinks, however, that the results are not very encouraging except in the cutaneous varieties. Concerning the use of the Roentgen rays after operation for the purpose of preventing a recurrence, the author says: "By intensive ray treatment the blood-forming organs are seriously damaged. The cells of the bone-marrow, the spleen, and the lymphatic tissues react strongly to the Roentgen and radium rays with nuclear destruction. On account of the great importance which the blood-forming organs possess when in good function as a prophylactic against carcinoma it is not probable that by the use of the rays alone the percentage of recurrences is materially reduced. Experience with Roentgen carcinoma has shown that by the too frequent use of the rays the disposition to carcinoma may be even increased." Much the same views are expressed about radium and radio-active substances. The author says: "A pronounced elective effect of radium on the carcinoma cells is not present. Simply the carcinoma cells are more sensitive and react sooner than the normal cells, but the normal tissues do not remain unharmed."

Attention is called to the fact that destructive changes may take place in the healthy tissues which at first are not apparent and that in a number of cases extensive sloughing of the bladder and rectal walls has taken place months after the use of radium in carcinoma of the uterus, and that in carcinoma of the rectum extensive strictures have occurred without the carcinoma being healed. According to the author radium has not given much better results than Roentgen rays as a rule, and in many cases the Roentgen rays are to be preferred. Other methods of treatment discussed are diathermia, fulguration, chemotherapy, the injection of tumor extracts, autotherapy, and the injection of organ extracts. The author thinks he has seen some benefit from the use of diathermia and the injection of organ extracts, and recommends this treatment as a routine after operation in order to prevent recurrence. The work is another evidence of the great effort that is being made at the present time to solve the problem of cancer.

The Life and Letters of Nathan Smith, M.B., M.D. By Emily A. Smith. With an Introduction by William H. Welch, M.D., LL.D. Cloth. Price, $2.25. Pp., 185, with illustrations. New Haven: Yale University Press, 1914.

Nathan Smith was one of the makers of the history of medicine in New England. Not only this, but he was one of the most important characters in American medicine during the first three decades of the last century. Hence anything that contains facts regarding him or his work naturally must be of interest to medical men.

A good portion of this book is devoted to his letters to his pupil and friend, Dr. George C. Shattuck. These are especially interesting and enlightening, not only regarding Dr. Nathan Smith and his work, but also concerning conditions that prevailed at the time. Dr. Shattuck seems to have been a useful friend, if we may judge from the correspondence: "I wish also," Dr. Smith writes from Hanover, Sept. 15, 1807, "that you would apply to Mr. Dunn or Mr. Maynard, whom you think best, and procure of them on my account several things, viz.: one dozen oil flasks and one pound each of the following: nitric acid, muriatic acid and sulphuric acid. . . . I wish also, that if they can be obtained in Boston, that you would procure for me some earthen and glass retorts." And this from another letter to Dr. Shattuck: "I am continually troubling you about many things. I wish now that you would be so kind as to procure for me two tin reflectors and a tin canister, which you will find described in Henry's Chemistry, in his chapter on Caloric. If you can find a tinman who will make them for you, and you will transmit them to me by Mr. Williams, or Mr. E. Woodward; it would oblige me very much. I shall soon be able to transmit to you the means of paying for these things." In another letter, we read: "If you have a man in Boston who makes thermometers," etc. These are samples from his letters to Dr. Shattuck and they show the "practical" friendship that existed between these two historic medical characters. But, more important, they give us a glimpse of Dr. Smith's scientific interests and activities.

Dr. Smith is best known in connection with his work in medical education. He was the founder of the medical school of Dartmouth College and for some time the whole faculty. When this college was well started he was called to the new medical school at Yale, as "professor of theory and practice of physics, surgery and obstetrics"—a position which he held until his death. Meanwhile, another medical school was started and secured his services. This was at Bowdoin, in the new state of Maine. He was professor of theory and practice of medicine of Bowdoin for five years. Here his lectures were delivered in the summer and did not conflict with his work at New Haven. The University of Vermont started its medical department, the leading spirit in this enterprise being Dr. N. R. Smith, son of Dr. Nathan Smith. "While still faithfully discharging his duties at Yale and at Bowdoin, Dr. Nathan Smith visited the Burlington School and not only delivered courses of lectures there, but by constant correspondence with his son gave it the benefit of his wisdom and experience, thus as the colleague of his son in the enterprise aiding in the establishment of a fourth medical school in New England."

While instrumental in starting four medical schools, he was not a believer in multiplicity, for he says in one of his Shattuck letters, "I think the four schools which I have been concerned in bringing forward, in addition to Howard, will be as much as New England will bear." And then farther on he adds—and if he were living to-day it is quite likely he would make the same statement—"Every state should have one medical school and no more."

Those who are interested in the medical history of the United States will find this book not only profitable reading, but full of some interesting historical data.

Recreations of a Physician. By A. Stuart M. Chisholm. Cloth. Price, $2. Pp. 328. New York: G. P. Putnam's Sons, 1914.

This book contains ten essays on various subjects. Five—"Banquo," "The Symbolism of Names," "Royal Authors," "On Some Translations of Horace," and "The Picaro in Fiction"—are literary and historical, rather than medical. They make not only interesting, but also instructive reading for any one who appreciates good things. The chapters of special interest to physicians are: "Specialization," "Physicians as Men of Letters," "The Inherited Spirit of Medicine," "Some Features of the Science of Medicine in the Seventeenth Century," and "On the Prevention of Disease." They are all full of information. The chapter on the prevention of disease is a historical account of the development of quarantine, and of inoculation and vaccination against small-pox; also an account of the plague visitations, of the origin and development of the science of bacteriology, of the discovery of the transmission of yellow fever, etc. This chapter alone is worth the price of the book. The one on physicians as men of letters is a revelation. It shows that medical men have influenced literature much more than most of us imagine, and that more noted men of letters were disciples of Æsculapius than is generally understood.

These essays reveal their author as a physician of wide reading, who has been industrious in his recreation. Each of the essays is well and interestingly written, and, more important, is instructive.

The American Encyclopedia and Dictionary of Ophthalmology. Edited by Casey A. Wood, M.D., C.M., D.C.L., Professor of Ophthalmology, College of Medicine, University of Illinois. Volume III. Cataract in Diabetes to Cocain Carbolate. Cloth. Price, $6. Chicago: Cleveland Press, 1914.

Chief topics in this volume are cataract, ocular relations of neighboring cavities and choked disk. Each of these important subjects is treated in a full and thorough manner, the first occupying 269 pages, giving an indication of the monumental character of the work. The pace set in former volumes is well kept, there being the usual defects and excellences of style and quality incident to varied authorship of the different articles. As a minor defect might be mentioned the use in legends of such expressions as "Author's irrigator," etc. It would be much better to give the irrigator the name of the author of the article, avoiding the necessity of looking up the author's initials at the end of the article and then referring to the authors' key in the beginning of the volume. To the editor and his collaborators are due congratulations on the rapid progress of the work.

Radium Therapeutics. By N. S. Finzi, M.B., M.R.C.S., L.R.C.P., Chief Assistant in the X-Ray Department, St. Bartholomew's Hospital. Cloth. Price, $2. Pp., 112, with 25 illustrations. New York: Oxford University Press, 1913.

The author's effort in this little book has been, he says, "to place before the profession a brief and clear account of the action and (therapeutic) uses of radium and its rays." And it may be said at once that he has succeeded well in this rather difficult and altogether laudable task. He has first written very clearly of the physics of radium and of the technic of its therapeutic application, and, best of all, has given an account of what is known from histologic study of its effects on tissues; so that he puts its therapeutics uses on a rational foundation. His summaries of its value in various diseases are brief but explicit; and he is blessed with experience and a fine conservatism, so that his judgment on its value is sane and not overenthusiastic. The book is an excellent one in a difficult field.

Manual of Surgery. By Alexis Thomson, Professor of Surgery, University of Edinburgh, and Alexander Miles, Surgeon Edinburgh Royal Infirmary. Cloth. Second Edition. Volume III—Operative Surgery. Price, $3.50. Pp., 620, with 255 illustrations. New York: Oxford University Press, 1913.

The convenient size, large print, the many good illustrations and a splendid text combine to make this book a welcome addition to the surgeon's library. It is written concisely but clearly, and the field is covered fairly well. The work of American surgeons receives the attention it deserves, although so well-known and popular an operation as the Andrews imbrication in connection with inguinal hernia is not mentioned. The usual division of the subjects treated is made. The closing chapter on anesthesia is good. It is short but gives much valuable information. Whether or not it should have a place in a book of this kind is open to question.

Infant-Feeding. By Clifford G. Grulee, A.M., M.D., Assistant Professor of Pediatrics at Rush Medical College. Second Edition. Cloth. Price, $3. Pp., 314, with 29 illustrations. Philadelphia: W. B. Saunders Company, 1914.

The author in revising his book has made no radical changes, but has endeavored to add the substance of the accumulated scientific data of the two years since the original publication. It is a good practical presentation of the theories and classification of Finkelstein, of Meyer, of Czerny and of Keller on the infant-feeding problem. Supplemented by observations from the author's own experience.

Miscellany

Oil of Chenopodium as a Substitute for Thymol in Hookworm Disease

Thymol, largely used in the treatment of hookworm, is one of the many drugs which has increased in price as a result of the present European war. In a recent article Motter (*Pub. Health Rep.*, Oct. 2, 1914, p. 2651) discusses the substitution for thymol of an American drug, oil of chenopodium. As indicated by its popular name, wormseed oil, this drug has long had a reputation as a vermifuge. The plant from which it is obtained grows in waste places practically all over the United States. The oil is produced chiefly in Maryland, and the seed comes to a considerable extent from Maryland and Florida. It is said that oils distilled by different processes and from seed grown in different localities vary in efficacy. The value of the drug in the treatment of roundworms is recognized, and Schüffner and Vervoort (*München. med. Wchnschr.*, 1913, lx, 129) found it superior to thymol, naphthol or eucalyptus oil in the treatment of hookworm. Oil of chenopodium paralyzes but does not kill the parasite, which must be removed by free purgation. Unlike aspidium and thymol, wormseed oil can be followed by castor oil, which does not increase the toxicity. Schüffner and Vervoort gave 16 drops of wormseed oil every two hours for three doses; two hours afterward, a tablespoonful of castor oil with a teaspoonful of chloroform. Gockel gives the single dose as 8 drops for patients 6 to 8 years; 10 drops, 9 to 10 years; 12 drops, 11 to 16 years; over 16 years, 12 to 16 drops. If inordinate sleepiness, depression or other untoward symptoms occur, the chenopodium must be stopped at once, active purgation induced, and stimulation by oral or rectal administration of strong hot coffee begun.

Medical Education of An Earlier Day

The *London Magazine*, a journal of note a century ago, in one of its issues during 1825 contains a somewhat satirical "dig" at the medical education of that period. One item reads:

"There are 3,500 medical practitioners in London, 900 in Paris, and not one in Jericho. If you ask aloud in the street in New York, How do you do, doctor? not fewer than nine passengers will answer you."

Concerning medical education in the British Isles, it says:

"We understand that there is a university called the University of Edinburgh, where ragged Scotch louts spend twenty or thirty pounds, and six months, in acquiring what is called medical knowledge. Others, richer and less ragged, spend three years, and twice as many hundred pounds; a few may occupy four or five. In Glasgow, they do pretty much the same. In both, they talk what is called Latin, and pay thirty pounds at the ends of these probations, have a velvet cap put on their heads, hear a speech from a man called a principal, and become M.D.—Doctors of Physic, or Medicine, for it is not absolutely agreed which (vide Term Reports, anno 1773. Boswell v. Johnson).—At Aberdeen again, physic is studied, learnt, acquired, for thirteen pounds twelve shillings, in about half an hour; *attendance*, on account of its inconvenience, being excused. At St. Andrew's, the facility is about as great; and thus, for thirteen pounds twelve shillings, a man acquires the right of 'purgandi, seignandi, accidendi, et trucidandi, impune per totam terram.' At Oxford and Cambridge, physic is acquired with the utmost certainty and facility, just as are other things in the same places; at Paris, Leyden, Göttingen *and elsewhere*, in other modes too tedious to detail. In England, generally, a student labors for seven years in spreading plasters, tying labels on bottles and applying packthread; but, *in London*, they dig up dead bodies and carve them, walk about an hospital and pay fifty guineas a year for the privilage of guessing what a man called an apothecary means, and what becomes of the money. Added to all this, in times of war, they go to the Peninsula, hew down legs and arms, and bore holes in skulls with a center bit, or do the same thing on board of a frigate. Then a few privileged ones wear scarlet cloaks, make a Latin speech, or listen to one, once in two hundred years, and vote all the rest to be ignoramuses."

Hospital Liable for Death of Delirious Patient Jumping from Window

(Wetzel vs. Omaha Maternity and General Hospital Association (Neb.), 148 N. W. R. 582)

The Supreme Court of Nebraska affirms a judgment against the defendant for $5,500 damages for the death of a patient who, while delirious, jumped from an unguarded window of his room on the third floor of the hospital, in the absence of the nurse, who said that she had not been gone five minutes, while another witness said it was nearly an hour. The defendant contended that there was no evidence of actionable negligence, particularly as the contract was to give the patient general, and not special, care, that the attending physician was selected by the patient or his friends, and that the nurse obeyed all of the physician's instructions. But the court points out that there was testimony tending to show that the patient, having typhoid fever in his own home, was taken to the hospital for better care and attention. When the hospital was called up by telephone to make arrangements for his care, it was said by whoever answered that general care was sufficient for a patient in such condition. The hospital was advised in advance that the patient had been delirious. To protect him from harm, the hospital nurse, on her own initiative, but with the subsequent approval of the physician, kept him for a time strapped to his bed. Then, though his fever remained high and his delirium continued, the straps were released by direction of the physician to permit frequent change of position, made necessary by premonitions of hypostatic pneumonia. The lower sash of the window was movable, unfastened and unprotected when he jumped out.

As law, the court holds that a hospital, incorporated and conducted for private gain, is liable in damages to patients for the negligence of its nurses and other employees. This rule of law rests on the general principle that a master is responsible for the torts or wrongful acts of a servant in the scope of his employment; and this doctrine applies to a hospital receiving for special care delirious patients, who on account of temporary conditions produce by fever or other ailments are not accountable for their own acts or conduct. A patient is generally admitted to a hospital, conducted for private gain, under an implied obligation that he shall receive such reasonable care and attention for his safety as his mental and physical condition, if known, may require. Any other rule would be a reproach to the law and to the hospital management. In the present case the evidence was sufficient to justify a finding that the patient was received under circumstances entitling him to the benefit of the principle stated. Duties which a hospital as such owes to a patient cannot be evaded by proof that the hospital nurse obeyed the instructions of the physician employed by him. Nurses necessarily have charge of delirious patients during the absence of physicians, while the responsibility of the hospital continues. Under the circumstances of this case, self-injury might well have been foreseen. It cannot be said as a matter of law that there was no proof of negligence on the part of the nurse or on the part of her employer. A nurse's absence of five minutes may amount to negligence. The question of negligence, under the circumstances here, was one of fact for the jury.

Roentgen Ray Liability—Changing Physicians—Expert Evidence

(George vs. Shannon (Kan.), 142 Pac. R. 967)

The Supreme Court of Kansas affirms a judgment against the defendant, a physician, for injury to the plaintiff in the negligent use of the Roentgen-ray machine in endeavoring to ascertain whether or not he had a stone in the kidney. The defense was that it was necessary to use the machine, that the plaintiff agreed to it, that if any injury resulted it was on account of the plaintiff's susceptibility to Roentgen-ray action, which could not in the exercise of ordinary care, caution and skill have been ascertained, and that if any burn developed as a result of the operation, it was through the plaintiff's own fault and negligence, and through his failure to follow the instructions to return to the defendant for further treatment.

The court holds that there was no error in an instruction to the jury that if the taking of such pictures in a proper and careful manner does not necessarily result in injury, then the fact that injury did result is some evidence (which may be rebutted) that proper care and skill were not exercised. Nor was there error in an instruction that "A physician is not released from liability for the burning of a patient by the use of the Roentgen ray by the fact that the patient quit the treatment of the physician after said patient was burned by the use of said Roentgen ray, and before said physician was willing that such patient should do so, or that said patient neglected to follow the instructions of the physician as to the use and care of the affected parts." The mere fact of discharging a physician or quitting his care and employing another physician by a patient who believes he has been injured by the negligence of the former physician is not in itself evidence of contributory negligence. In other words, the mere fact that a patient discharges or quits the care of his attending physician and employs another physician is not evidence of contributory negligence in an action by the patient against the former physician for negligence in the discharge of his duty to the patient. If any act of the plaintiff had been shown by the evidence to cause an aggravation of the injury, such evidence would probably have been pertinent in mitigation of damages, but the mere fact of a change of physicians did not raise the presumption that damages were increased thereby.

The defendant produced the testimony of a number of physicians, who were Roentgen-ray operators, which tended to show that a burn would not be expected by the use of the Roentgen ray with less than two or three times the amount of current actually used in this case, as shown by the testimony. On the other hand, there was evidence that the use made of the Roentgen-ray machine and current would be expected in ordinary cases to inflict the burn which the plaintiff suffered. On such conflicting evidence it was the especial province of the jury to determine the fact. This is a question of science in which the average juryman has no special knowledge to enable him to test the credibility and accuracy of testimony; still it does not follow that the mere number of witnesses on either side determines the preponderance of the evidence.

Patient Who Testifies Waives Privilege

(City of Tulsa vs. Wicker (Okla.), 141 Pac. R. 963)

The Supreme Court of Oklahoma holds that a patient, suing a third party for damages for personal injuries, testifying as to the nature and extent of her injuries, and the time and place of treatment, waives the privilege granted by the statute, and renders admissible the testimony of her physician on those subjects. In this case Mrs. Wicker sought to recover for personal injuries alleged to have been occasioned by the negligence of the city in not guarding a dangerous excavation in the streets. During the trial she offered herself as a witness and testified as to the nature and extent of her injuries, as also that she consulted a certain physician, who prescribed for her, she remaining under his care about six months, after which time she called at his office for treatment on various occasions. The city endeavored to ascertain from the physician for what, if anything, he had treated her, and offered to show that he had never at any time prescribed or treated her for an injury to her hip received at the time of the alleged injury. The court holds that it was error to exclude the testimony of the physician, after the plaintiff had voluntarily testified as she had, as it was material, and the attending physician was best qualified to testify as to the nature and extent, time and place of the treatment of the injuries.

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting held Oct. 28, 1914

The President, Dr. William Duffield Robinson, in the Chair

Abdominal Pain; Its Significance and Diagnostic Value

Dr. John B. Deaver: At least 90 per cent. of all diseases begin with pain or give rise to it at some time in their course. Ordinarily, pain is the result of undue stimulation of nerve fibers by mechanical, chemical or thermal agents. Such pain is objective. There is a type of pain which has no external physical basis. It is a product of disordered mental action. This is subjective pain and is illustrated in the phenomena of hysteria. Such pain belongs to the domain of the neurologist. It is a confession of ignorance to give to pain a name which has no pathologic significance. All the various "algias" should be replaced by terms conveying an understanding of the underlying processes.

The first great obstacle to the appreciation of the significance of abdominal pain has been the belief that pain in this region usually was the result of disordered function. The second great difficulty in abdominal diagnosis is the inability of the nervous system accurately to localize sensations received from visceral areas. Pain in the abdomen is per se no evidence that the lesion is in the abdomen. Abdominal pain associated with pleurisy or pneumonia, particularly in children, is probably of a reflex nature. Angina may give rise to intense epigastric pain simulating acute surgical disease of the upper abdomen. It is in the milder forms and beginnings of disease that the location of pain is of the greatest value. Of all the organs in the abdomen the stomach presents the greatest variety of symptoms and the most difficult to analyze. If general disease of the stomach is excluded, gastric symptoms should prompt a careful and systematic survey of the abdominal organs. Insignificant chronic disease of the appendix may set up pylorospasm with pain, retention, fermentation and secondary gastritis. It is of the utmost importance to investigate the right iliac fossa of every case presenting epigastric symptoms commonly referred to the stomach. The diseased gall-bladder frequently masquerades as a gastric affection.

Abdominal adhesions are a common source of pain and call for immediate surgical operation. This pain should never be treated with narcotics. At least a year should elapse before operative relief of postoperative adhesions is advised, except in the case of serious symptoms. There is too much morphin used as a routine measure after abdominal operations. When pain makes its appearance on the second or third day or later following operation, the conditions chiefly to be considered are simple distention, peritonitis and obstruction. The most important single feature in differentiation is the character of the pain, whether wave-like and intermittent, or steady and associated with tenderness. The pain of distention and obstruction is, as a rule, colicky and wave-like; that of peritonitis, more steady, diffuse and unremitting.

DISCUSSION

Dr. John B. McAlister, Harrisburg: We often are unable to interpret the language of these pains, and in spite of all our knowledge of anatomy and pathology in the abdomen, exploratory operations for diagnostic purposes will be made. I was called to see a woman who was taken suddenly with severe pain which I felt sure was characteristic of renal colic. Operation revealed a fibroid tumor with considerable colloid degeneration. The woman had been in apparently good health until that attack of pain. I could not account for the severe pain except that there may have been a twisted pedicle. Another pain in the upper abdomen which is of supreme importance is that of acute pancreatitis or hemorrhagic pancreatitis. I have seen four of these cases. In the first and second cases the diagnosis was made at the necropsy; in the third and fourth the diagnosis was confirmed at the necropsy. The patients were adults without history of previous ill health.

Dr. J. Leslie Ellenberger, Harrisburg: Pain is a signal that something is wrong. We should not expect to get rid of pain without removal of the cause, and in ascertaining the cause the utmost care is necessary. I have seen a case presenting all the typical symptoms of appendicitis on admission to the hospital and on the following morning show signs of pneumonia.

Dr. Joseph Sailer: Pain is a subjective affair, something felt by the patient, which we cannot measure; and, while experience may give us a proper estimate of the patient's manifestation of pain, we may be deceived by those who exaggerate or underestimate its degree. It is astonishing how often patients with valvular heart disease and with tuberculosis of the lungs come to the physician complaining of gastric symptoms. Acute endocarditis in the early stages may so simulate abdominal conditions that operation may seem imperative.

Dr. Wilmer Krusen: I would emphasize the necessity of a bimanual examination in all cases of appendicitis to determine whether the appendicitis is coexistent with pelvic disease or whether all the symptoms are due to salpingitis. The pain of ectopic pregnancy is of such gravity that physicians should be mindful of its possibility in cases of abdominal pain. Also to be considered are the pains associated with neoplasms. In fibroid tumors there is pain due to pressure conditions. In no condition in gynecology is pain so beneficent as in malignancy. The surgeon would welcome the fact that a woman with beginning cancer had pain.

Dr. A. C. Morgan: It is very important that we differentiate between acute and chronic pain. In a large percentage of cases acute pain constitutes a surgical condition calling for prompt action to save the patient's life. I regard the term "dyspepsia" as a very dangerous one, because this condition is not present, but the stomach is giving us warning of trouble elsewhere. The man who is content with the routine treatment of "dyspepsia" with nux vomica, etc., is careless or ignorant and is not a credit to the profession.

Dr. James Tyson: I was called yesterday to see a patient with abdominal pain, paroxysmal in character, and with a history of traumatism. The attacks of pain were of slowly increasing severity, resulting in collapse. The patient's abdomen was swollen and to my inquiry of the location of pain he replied that it was general. Passing my fingers in the region of the appendix I found evident tenderness, yet there was nothing that was distinctive. I have not yet made a diagnosis of this case.

Dr. S. Solis Cohen: I would not eliminate functional disturbance of the viscus from among those conditions giving rise to pain in the abdomen. Organic disease is often overlooked from want of careful examination, but when careful study has been made, and the evidence points to the so-called functional disturbance, then the physician is justified in carrying out medical measures. Several times in my experience I have been unable to exclude appendicitis, gall-stones or gastric ulcer without exploratory operation. A better understanding of the great sympathetic nervous system would give us more light on such cases. There is such a condition as hysteria, but ninety-nine cases out of a hundred called hysteria are something else. In such cases I would advise exploratory operation. I want to confirm the comparative frequency with which acute pancreatitis expresses itself as epigastric pain. I have known cases in which death occurred prematurely because the significance of the pain was not realized. To make a diagnosis one must not study pain or any other symptom alone, but must study his patient thoroughly.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

Fortieth Annual Meeting, held at Cincinnati, Oct. 27-29, 1914

(Concluded from page 1787)

Certain Physical Signs Referable to the Diaphragm and Their Importance in Diagnosis

Dr. Richard Dexter, Cleveland: Conditions which involve the diaphragm may be divided into two groups: 1. Those in which the symptoms of involvement depend on the irritation of the nerves which supply the diaphragm. 2. Those cases in which the position of the diaphragm is affected. Irritations of the pleural or peritoneal coverings of the diaphragm give rise to symptoms at a distance from the structure. The paths of pain distribution conform to type of the viscerosensory reflex in the sense of Mackenzie and Head. The inspiratory contraction of the diaphragm tends to draw the subcostal angle toward the median line. Under normal conditions this contraction is not strong enough to overcome the antagonistic action of the scalene and intercostal muscles. When the position of the diaphragm is lower than normal the contraction of the muscle will be more direct, and will, therefore, equalize or overcome the action of the scalenes and intercostals. The result will be a retraction of the costal angle toward the median line during inspiration. If the diaphragm is pushed up from below the power of its contraction will be lessened with the result that the subcostal angle will depart farther from the median line than usual.

Relation of Gastro-Intestinal Tract to Joint Disturbance; Value of Eliminative Treatment

Dr. William A. Mowry, French Lick, Ind.: Derangements of the gastro-intestinal tract operate in the production of chronic affections, such as rheumatism, gout, obesity and probably diabetes. Among 244 patients suffering from joint disturbance, 59 had true gout and 93 had autotoxemic arthritis. Most of the cases were of the chronic type. The fingers and knees were affected equally in two-thirds of the cases, with toes, wrists, ankles and elbows next in order of frequency. Constipation was very frequent in these patients, a few had diarrhea, while some complained of alternating constipation and diarrhea. Only one-third gave a history of headache, usually coincident with stomach or bowel attacks. In forty-eight per cent. of the cases mucus was present in the stools, constantly or intermittently. About half of the patients complained of some form of indigestion, most frequently with eructation and regurgitations. Examination in most cases confirmed the diagnosis of gastritis, colitis, chronic appendicitis and probably cholecystitis. Immediate relief was given by internal irrigation, free purgation and diet. Salicylates were used in the autotoxemic group for the relief from pain, while fomentations and other hydrotherapeutic measures were regulated for each individual patient. Laxative waters were used; paraffin oil and castor oil were given when too large doses of a saline irritated the gastro-intestinal tracts. The results of treatment were most gratifying. Seventeen patients were relieved entirely from pain or stiffness in the joints; all but fifteen of the remaining showed marked improvement. Patients were instructed as to the importance of diet and regulation of the bowels to insure permanent benefit.

Presidential Address: The Public and the Profession

Dr. D'Orsay Hecht, Chicago: The physicians of to-day are wading up to their necks into mysteries of research. The evenings are spent in dutiful attendance at the meetings of the medical society, and the nights under an avalanche of medical journals. There is a lamentable show of personal indifference for the microscope and test-tube. The commercialized general laboratory is an outgrowth of this. Another instance of our tension is the bread and butter physician's restless pursuit of research. Aside from the genuine fascination which the creative faculty is sure to have for some men of the academic type, there comes to my mind the thought that the many amateurs in research recruited from the heterogeneous mass of clinicians are attracted to it by the glamor of the name. By it physicians are diverted from the paths of the clinic, paths quite as congenial and in respect of their talents and equipment infinitely more promising. Medical society madness, instead of manifesting itself as a phase of the theory of relaxation, presents itself as a symptom of the gospel of intensive work, which it should not. There are thoughtful persons, appreciative of the work of the profession. Then there are others who capitalize themselves as antivaccinationists and antivivisectionists. The latter especially are even now spasmodically engaged in pseudoformidable campaigns against the very types of animal experimentation that have resulted in the greatest benefactions to man.

Conservative Versus Radical Treatment of Eclampsia

Dr. J. Henry Carstens, Detroit: Pregnant women should have their blood-pressure taken frequently and also have the urine examined. If symptoms of toxemia develop, a most restrictive diet should be started and the woman placed in a position where she can have prompt medical attendance, preferably in a hospital. If convulsions occur, premature delivery should be brought about by slow process, if the case is mild. In severe attacks of convulsions, immediate delivery should be instituted by the so-called vaginal cesarean section, if the woman is about seven months' pregnant or thereabout. If the woman is at full term, and especially in a primipara, an abdominal cesarean section should be the operation of choice.

Salvarsanized Serum in the Treatment of Locomotor Ataxia, Paresis and Cerebrospinal Syphilis

Dr. William Litterer, Nashville, Tenn.: After giving ninety intraspinal injections of neosalvarsanized serum to fifteen patients over a period of ten months, I have seen in some of these cases remarkable improvement which has persisted up to the present time. With perfect aseptic and cautious doses the method is practically devoid of danger. On account of the numerous areas of poor vascularization in the brain and cord, the most rational treatment of nervous syphilis appears to be the intraspinal administration of salvarsanized serum. Whether it will entirely annihilate the spirochete or whether there may still remain inaccessible foci of infection, which will make recrudescence possible after the lapse of time, the future alone can determine.

Mortality and Morbidity of Appendicitis

Dr. F. F. Lawrence, Columbus, Ohio: The mortality is determined by: 1. The promptness of action after a correct diagnosis. 2. The period at which a correct diagnosis is made. 3. The patient, his resistance, his environment, and whether it is his first or one of many attacks. 4. The family doctor, his ability, his conscience and his courage. 5. The surgeon, his judgment, his skill, and his personal attention to detail. The morbidity depends on: 1. Delayed operations resulting in complications. 2. Abscess formation requiring prolonged drainage. 3. Inefficient drainage when drainage is required. 4. Incomplete operations. 5. Faulty technic which tends to irritate the peritoneal covering, strictures favoring adhesions, leaving the uncovered stump, disseminating infection by overlooking the physics of distention or of tension, and unnecessary trauma.

Present-Day Conception of the Treatment of Nephritis

Dr. Arthur R. Elliott, Chicago: Improvements in treatment may be summarized as a better handling of the cardiac problem, a better standard of control in diet, and improved prophylaxis. Chronic focal infection may play an important part in the etiology of chronic nephritis. As a primary measure in treatment, every case should be examined thoroughly for infective foci and these obliterated by radical treatment when found. Syphilis and chronic lead intoxication are other insidious factors that must be combated.

In the vast majority of cases of chronic nephritis, during the stage of cardiac compensation, the total function of the kidneys is well up to normal. Aided by periodic functional testing to check up the kidney condition the diet may be so regulated as to maintain general nutrition and kidney conservation on a parity. I perform fluid and salt excretion tests in every case of chronic nephritis before laying down the diet. The most important item in the treatment of chronic nephritis is the preservation of cardiac compensation. The high blood-pressure and cardiac hypertrophy of chronic nephritis constitute a compensatory mechanism enabling the kidneys to maintain adequate function. They consequently are essential to the preservation of life and should be protected by every hygienic and dietetic safeguard. High blood-pressure should not be made the object of direct therapeutic attack. Nitrites should be reserved for emergency use to combat such developments as angina, cardiac asthma, etc. The appearance of dropsy in primary chronic nephritis almost invariably signifies the advent of cardiac failure. At this stage the digitalis bodies become the mainstay of treatment and should not be withheld because the blood-pressure is high, as they act just as well or even better with a high blood-pressure as with a falling pressure.

Gall-Bladder Infections: Their Treatment From a Surgical Point of View

Dr. Louis Frank, Louisville: My operative work has been performed under gas-oxygen anesthesia and complete blocking, with preliminary drainage of the gall-bladder, and dividing the operation into two stages. After the gall-bladder has been permitted to drain for some time, and the patient's temperature has receded to normal and the jaundice has subsided, I do a secondary operation removing the obstruction from the duct. Under this plan the mortality has been materially reduced.

Anuria: Its Etiologic and Surgical Phases

Dr. Hugh Cabot, Boston: Anuria should be classified according to its pathology. There are two types, the secretory and the excretory types. Classified by clinical causes, there are three types, the neuropathic, the destructive and the obstructive types. The diagnosis of anuria is always simple. Diagnosis of the cause requires care, use of all the means at our disposal and accurate deduction. Operation must be considered in all cases not due to destruction of kidney tissue. In cases of acute nephritis operation may tide over an emergency, but is rarely indicated. In cases due to obstruction of the ureter from without, operation will relieve the obstruction and is indicated when the cause is wholly removable, as in benign tumors. Operation is always indicated in anuria due to obstruction within the ureter. If both sides are obstructed, both should be operated on at the same sitting. If one is obstructed and the other has stopped secreting from reflex or other causes, operation is indicated only on the obstructed side.

11 *Psychic Manifestations of Disease of Glands of Internal Secretion. E. M. Auer, Kalamazoo, Mich.

9. Mental Disturbances in Articular Rheumatism.—The exact cause or causes of mental disturbances during the course of acute articular rheumatism, Haskell states, are not clear. Many of the delirious episodes during the acute stage of the disease are undoubtedly pure fever delirium and should not be looked on in any sense as specific. There are those who, without other signs of psychopathic makeup, regularly show a delirium with only a slight rise in temperature. Such individuals may later develop an endogenous psychosis, seen not infrequently in manic-depressive patients. In the hyperpyretic cases, conveniently so-called, the increasingly high temperature is simply an expression of the extreme toxemia which is affecting the nervous mechanism of the heat regulating center as well as the brain cortex. Whether this toxemia is purely bacterial in origin is unknown. Kraepelin has utilized in the manufacture of a theory the observations that sometimes in these hyperpyretic cases all signs of joint involvement actually do disappear and suggests that the sudden resorption of this fluid floods the body with an excessive amount of some toxic substance which cannot be excreted or made innocuous fast enough to prevent damage to the cerebral cortex. In the protracted cases there are numerous additional factors. The prolonged toxemia, the altered metabolism as a result of this and the physical exhaustion from the disease, together, in many cases, with the added effects of various complications or several relapses of the polyarthritis, all serve to bring about the changes in the cerebral cortex.

The outcome in the superacute cases is imminently bad. The mortality is 82 per cent. In the acute infectious delirium the prognosis is more hopeful, but still serious. Fifty-two per cent. of this class die. In the more protracted cases of the late febrile or convalescent period the prognosis is uniformly good for recovery. The course is usually long, from several months to a year. The treatment is first that of the primary disease. Numerous reasons make it highly advisable that the patient be in a hospital and preferably one especially equipped for the treatment of acute mental conditions.

11. **Disease of Glands of Internal Secretion.**—Auer is of the opinion that in the etiology of the affective psychoses we are evidently dealing with a biologic disturbance. The glands of internal secretion physiologically act not as independent units but, on the contrary, mutually influence functional activity. The occurrence of insanity at puberty and adolescence after severe physical and mental strain and at the time of menopause, all periods when the metabolic changes of the body are intense, and the occurrence in syndromes unquestionably the result of disease of the glands of internal secretion of idiocy, imbecility, depression, mania and dementia suggest strongly that the true etiology of the affective psychoses lies in a functional disturbance of the glands of internal secretion.

22 Recent Traumatic Dislocations of Hip. C. R. Steinke, Philadelphia.
23 *Significance of Jackson Veil. D. N. Eisendrath and E. W. Schnoor, Chicago.

15. **Sarcoma of Long Bones.**—The chief requirement for the early diagnosis of sarcoma of the long bones, according to Coley, are a more careful study of all known clinical data; a larger clinical experience in the diagnosis of sarcoma of the long bones; early and repeated Roentgen-ray examinations in all cases of suspected swellings of the long bones, especially those following trauma; exploratory operation and microscopic examination of the tissue removed in selected cases, but not as a routine measure; realization of the importance of not placing implicit reliance on the negative report of the pathologist, especially when in conflict with clinical and Roentgen-ray evidence that is strongly positive.

16. **Treatment of Malignant Tumors by Radium.**—The hopes placed in radium as a new and successful means in the treatment of malignant tumors, Sparmann says, have not been realized. Moreover, the number of cases in which one might have recourse to radium therapeutics shrinks constantly as experience progresses.

17. **Ostitis Fibrosa Cystica.**—According to Landon the healing of fractures occurring at the site of these cysts is uniformly good and may result in cure of the cyst. Operative treatment, unless one can be quite sure from constant watching that the diagnosis is correct, is always justified. Although in selected cases and in the hands of experienced operators, resection with autogenous grafting has resulted favorably, curettement, crushing in of the walls and primary closure of the wound have been almost universally sufficient to procure a cure.

18. **Operations for Goiter.**—Of the 103 operations done by Frazier there were 80 thyroidectomies with no deaths. Of 3 thyroidectomies for malignant disease, there was one death, a sarcoma in a boy 11 years of age. Of 17 ligations, there were two deaths, both true exophthalmic goiters, one an acute case of six months' duration, the other a case in the terminal stage of the disease. The end results in the toxic cases were in accordance with those recorded from other clinics. Of the patients heard from, 90 per cent. had fully recovered or were greatly improved, and of the latter a number had been operated on within the last year. The completeness of cure, Frazier states, does not depend entirely on the successful removal of the gland. Two other factors must be considered: First, the care of the patients after the operation, which should, whenever possible, free the patient from physical and nervous strain for periods varying from several months to two years. The completeness of the recovery will depend on his appreciation of the need of this after-treatment and whether the circumstances permit of its enforcement. Second, the existence of chronic visceral disease at the time of the operation must be taken into account. Some of these patients are physical wrecks with organic lesions of heart, kidney and other organs, from which complete recovery is impossible.

Frazier emphasizes that the general practitioner has every right, if he so chooses, to try non-surgical means in the early stages of the disease before the myocardium or kidney or nervous system is permanently damaged. But if he fails to arrest the disease and does not advise operation in the curable stage, he should be just as severely censured as the practitioner who fails to call for surgical aid until his patient with acute appendicitis has developed peritonitis, or one with a callous ulcer of the stomach, carcinoma. The extraordinary recuperative power of patients with Graves' disease is amazing, and in most cases, sick as they are at the time of operation, they will almost uniformly be restored to perfect or reasonably good health.

20. **Technic of Eck Fistula.**—From a rather extensive use of the Eck fistula in dogs Peet considers the operation safe, entirely compatible with a normal life, and simple of execution. He prefers the modification of Carrel's technic. In cases of liver cirrhosis with ascites and in cases of thrombosis or other obstruction to the portal circulation, Peet considers the operation advisable, especially so in cases in which esophageal varices exist. In the latter condition, at least, he says, it should prove much superior to omentopexy.

24. **Anaphylactic Skin Reactions Excited in Hay-Fever.**—Fifty-eight cases giving a history of hay-fever were examined by Goodale. The extracts were prepared by soaking the pure pollen for twenty-four hours in 15 per cent. dilution of alcohol and filtering. Forty-five cases were examined with reference to grasses. It was observed that in all positive cases the red-top, timothy and blue grass equally excited reactions. Of these cases eight were affected by grass alone, none of the other plants tested exciting reaction. Thirteen cases were affected both by grasses and ragweed alone. Six cases showed positive reactions toward grasses, ragweed and golden-rod, and a variety of other plants. Three cases showed positive reactions to grasses and roses alone. The beach grass was tested in twenty-seven cases. This, although flowering late in the season, excited positive reactions in eleven cases of the spring form, fifteen cases being doubtful or negative.

Ragweed was tested in 49 cases. Of these, 45 were positive, 4 being negative; 13 were affected by ragweed alone, no other plants tested exciting reaction. Sixteen were positive with reference both to ragweed and to golden-rod, but not to other plants. One case showed positive reactions to grasses, ragweed and roses, but not to golden-rod or to other plants. Forty-nine cases in all were tested for golden-rod. Of these, 26 were positive, 23 being negative. One case only showed positive reaction to golden-rod alone, without disturbance from other plants, all of the other positive golden-rod cases reacting also to ragweed.

Twenty cases were tested for yarrow, 5 being positive, 15 doubtful or negative. Beach wormwood was tested in 6 cases, 2 of them showing moderate reaction, 4 being negative. Field daisy was tested in 14 cases, 5 of them showing a moderate reaction, 9 being doubtful or negative. Burdock and fall dandelion were tested in 3 cases, showing each 1 positive and 2 negative results. Hawkweed was examined in 17 cases, 5 being positive and 12 negative. English daisy (*Bellis perennis*) was examined in 20 cases, 4 being positive and 16 negative. Pigweed was examined in 26 cases. Three of these were positive, and 23 were negative. Wild carrot, or Queen Anne's lace, was examined in 23 cases, only 1 being positive and 22 negative. Tansy was examined in 12 cases, 2 being positive and 10 negative. Two types of roses were tested, the early flowering Japanese rose and the late flowering prairie rose. The Japanese rose was examined in 19 cases, 3 being positive, the remainder without reaction. The prairie rose was tested in 8 cases with negative results. The mock orange was tested in 6 cases, 2 of these being positive. Tests were also made in a few cases with negative results of the following plants: California poppy, hawthorne, bayberry, frost grape, jack pine, peony, white oak, rhododendron, hardhack.

26. **Asthma in Children.**—Talbot is of opinion that the evidence at hand points to the fact that asthma is a manifestation of anaphylaxis, namely, a local manifestation in the lungs. It is conceivable that the urticaria which is seen on the skin may also come on the mucous membrane of the bronchi, and thus cause the symptoms of asthma. Asthma in a certain number of children is due to egg poisoning. Scarification of the skin and inoculation with egg white will show whether egg albumin is the specific cause of the asthma. Many, if not all cases of egg asthma may be immunized to egg white by feeding them with gradually increasing doses of egg albumin in capsules. When the egg idiosyncrasy is cured the asthma stops unless an idiosyncrasy to some other protein complicates the situation. Horse-asthma is an anaphylactic phenomenon due to protein of the horse and may be recognized by scarifying the skin and applying horse-serum. A similar reaction to the egg reaction results.

29. **Three Methods for Diagnosis of Tuberculosis by Sputum Examination.**—The methods used by Ertischek are as follows: 1. Direct smear. 2. Antiformin digestion. 3. Salting method of Davis. Out of 168 specimens examined, which form the basis of this report, 149 were negative to all three methods. Direct smear found four positives that the antiformin did not. Direct smear found six positives that salting did not. Antiformin found six positives that salting did not. Antiformin found four positives that direct smear did not. Salt solution found six positives that direct smear did not. Salt solution found six positives that antiformin did not. Three specimens were positive to all methods.

92. **Albumin in Sputum and Its Relation to Pulmonary Disease.**—The following technic is used by Callender after trials of all other recorded methods, and it is recommended for those who desire to continue work with this procedure. Twenty-four-hour amounts of sputum are collected and examined fresh. The material is placed in a glass-stoppered flask, and equal quantity of 3 per cent. acetic acid added, and the mass rendered homogeneous by shaking. Allow to stand for five minutes and filter. Add 1 drop of glacial acetic acid to the filtrate to be sure of complete precipitation of mucin and repeat filtration if necessary. Take a convenient quantity, as 4 c.c., and add an equal volume of supersaturated magnesium sulphate solution, about 80 per cent. (This solution may be used at 60 C. and kept in the 37.5 C. incubator). This precipitates globulin. To another similar portion add 5 drops of 10 per cent. potassium ferrocyanid to precipitate albumin. If much globulin is found to be present by the first determination it will be necessary to filter it out before proceeding with the test as the ferrocyanid precipitates both. Except in work involving an estimation of the prognosis and cases in which globulin is more than an opalescence, this is rarely necessary. In the case of globulin precipitates form slowly and tend to remain in suspension. It was found that the heavy clouds formed in the reaction will form precipitates if given a little time. The negatives then are reactions showing no change in the clarity of the material or an opalescence or cloudiness that does not settle as a precipitate and such as may be obtained from the sputum of persons with no respiratory disease.

One hundred and eight cases are reported. Incipient active cases all showed a positive reaction. Of the moderately advanced cases 40, or 80 per cent., were positive and of the far advanced 90.3 per cent. contained albumin. One of the negative cases in the far advanced series was clinically in extremis, but repeated trials failed to show the reaction. Of fibrous cases 10 cases were examined in a separate group. Of these, 2, or 20 per cent., were positive for both albumin and globulin; the rest being negative for both. Both of the positive cases showed periodically tubercle bacilli in the sputum. A cardiac case, showed during partial compensation a plus reaction. Two months later, when compensation was complete, though raising some sputum, the reaction was negative. Two cases of bronchial asthma were repeatedly negative. A case of pulmonary syphilis showed abundant precipitates of both albumin and globulin. A case of fibrinous bronchitis, showed at all times a small amount of albumin not estimable quantitatively. A case of subacute bronchitis and a case of bronchiectasis, similarly showed small amounts of albumin. Two cases of subacute rhinitis and nasopharyngitis showed constantly in the purulent sputum a small amount of serum albumin.

Three cases in which artificial pneumothorax had been produced showed on first examination a trace of globulin and a heavy albumin precipitate. Two months later all three cases clinically showed a marked improvement and in all three the globulin had increased to a double plus reaction while the albumin was present only in traces. Callender concludes that albumin is not present in the sputum from all cases of active pulmonary tuberculosis. An increase in globulin, accompanied by a decrease in albumin, is a favorable prognostic sign. Albumin is present in the sputum from cases of pulmonary syphilis and is therefore not a means of differential diagnosis between that disease and phthisis. As a general rule, though there are exceptions, the albumin content corresponds to the amount of activity. Fibrous cases with moisture but no active tuberculosis in the lungs do not show appreciable amounts of albumin in the sputum.

101. **General Anesthesia with Reference to Surgery of Genito-Urinary Tract.**—Most patients to be anesthetized, either locally or generally, Gwathmey urges, should have the benefit of physiologic doses of morphin before anesthesia, and also of an alkali, and carbohydrate treatment both before and after operation. For very weak and feeble patients, for those in the extremes of life, or where exhaustion with acidosis is present; also where the patient is in a state of coma or has acute or subacute nephritis, or any respiratory affection, the morphin should be omitted and bromids, or paraldehyd and olive oil, per rectum, should be substituted. The essence of orange-chloroform-ether sequence, or the nitrous oxid-oxygen-ether sequence should be used instead of ether by the drop method or the "gas-ether" sequence. Chloroform throughout is the anesthetic of choice for chronic alcoholics in fair condition. Oil-ether colonic anesthesia is indicated for the very obese. For office work and short operations, it is both safe and satisfactory to use only nitrous oxid and oxygen, without any preliminary medication or the addition of ether. For major operations in genito-urinary surgery, patients can be narcotized with nitrous oxid and oxygen alone, if proper preliminary medication is given, and this combination should be more frequently employed.

120. **Surgery of Gastric and Duodenal Ulcer.**—Out of a total of 334 gastro-enterostomies for gastric ulcer done by von Eiselsberg, seventeen patients died after the operation. In twelve of these the ulcer was recent. Eight died from causes referable to the ulcer itself; for instance, hemorrhage from the ulcer, due to a continuing progressive ulceration. There were 317 recoveries with 134 cures. In eight of thirty-one unrelieved cases, the ulcer was situated at the pylorus. In eleven cases the ulcer was situated at a distance from the pylorus. Eight cases were duodenal ulcers. In four cases the ulcer was not located; there were adhesions and probably the ulcers were duodenal. The interesting point demonstrated by these thirty-one cases is that ulcers situated at a distance from the pylorus are not so greatly influenced by gastro-enterostomy as those situated at the pylorus. First among the causes which are responsible for failure to cure by operation is the development of a postoperative peptic ulcer of the jejunum. This occurred seven times in 334 gastro-enterostomies.

Thirteen patients, or about 10 per cent., died of cancer of the stomach. In six the continuance of the growth and the development of the ulcer after the operation were the causes of death. In one of these six cases, the patient developed morphin habit through the pain he suffered, and died; another died from hemorrhage; another died following perforation of the ulcer; another had very severe pain and hemorrhage; jejunostomy was performed, but the patient committed suicide; and finally in one case the pains continued, but further details are unknown. Three patients died of tuberculosis of the lungs. One patient died of tumor of the suprarenal body. The cause of death in the remainder is unknown.

In thirty-six cases of ulcerative processes in the stomach and duodenum, unilateral pyloric exclusion was performed. Eleven patients made a complete recovery after the operation. Of four cases unrelieved, in one the whole ulcer was extirpated to relieve the continued pain, and cure followed; one patient still suffers from attacks of hemorrhage; and two patients developed symptoms of peptic ulcers. Of three who died at a later date, one developed cancer of the stomach and two patients developed peptic ulcers.

Von Eiselsberg observed the formation of peptic ulcers seven times in gastro-enterostomies. In addition to this he has found peptic ulcers in five patients on whom gastro-enterostomies had been done by other surgeons and in one of whom he did relaparotomies. Four patients developed symptoms of peptic ulcer following unilateral pyloric exclusion. In the seventeen cases the chief symptom was the development of a very painful induration in the neighborhood of the gastro-enterostomy fistula, the discomfort and pain becoming so great that one could scarcely touch the spot. Von Eiselsberg emphasizes that whenever possible the peptic ulcer should be excised.

123. **Is Thrombo-Angeitis Obliterans an Infectious Disease?**—This question is answered by Buerger in the affirmative. He says that thrombo-angeitis obliterans is a disease in which an acute inflammatory lesion and occlusive thrombosis of arteries and veins are the characteristic lesions. From the mechanical point of view and from the point of view of symptomatology, the thrombotic occlusion is the most important phenomenon. The thrombosis is probably preceded, and certainly accompanied, by an acute inflammatory or exudative stage. The lesion involves deep veins in about 40 per cent. and the superficial veins of the upper and lower extremity in 20 per cent. of the cases. Recent investigations of the veins show that the acute lesions in the superficial vessels and the deep vessels are identical. The histologic changes in the veins point to the existence of an infectious process. Buerger believes that future studies should be directed toward the discovery of the causative agent in specimens cut out from the superficial veins when they are the seat of the acute thrombophlebitis. In this way it is hoped that the etiology of the disease may soon become revealed.

124. Abstracted in The Journal, June 20, p. 1987.

127. **Regeneration of Cartilage and Bone.**—It is Haas' opinion that the periosteum is directly and actively concerned in the regeneration of bone. In the early stages the periosteum proliferates to form a cartilaginous tissue, which is later transformed into bone. The exact method of the changes from cartilage to bone cannot be determined. There is considerable evidence in favor of the direct change of the cartilage-cell into the bone-cell. There is at times the appearance of the osteoblast forming bone and substituting the cartilage. Therefore it seems to Haas that both processes can take place at the same time. The regeneration of bone also takes place from the marrow and cortical bone, but in a more limited degree and at a later period than that from the periosteum. The regeneration of cartilage takes place almost entirely from the perichondrium. It proceeds by a direct proliferation of all the layers of the perichondrium beneath the outer fibrous tissue. There is some evidence in favor of the view that the connective tissue is also transformed into cartilage under the stimulation of the neighboring cartilage or perichondrium. There is a slight amount of regeneration of cartilage from the original cartilage near the perichondrium, but the remainder of the cut end tends to undergo degenerative changes. The extent of the removed cartilage exerts no influence on the regeneration.

128. **Disease of Glands of Internal Secretion in Gynecologic Patients.**—The following facts are emphasized by Frank. The glands of internal secretion control and regulate many

vital processes, including development, growth, nervous impulses, psychic manifestation, metabolism and reproduction. Each gland, regarded individually, exerts a predominant influence on one or more of these functions. In order to produce a perfect individual and maintain perfect health, the interaction of these glands must be normal. Disturbance of this perfect interrelation reacts on the genital sphere in only one of two ways—in an increase or a decrease of function. The gonads, in turn, may react on one or more of the other ductless glands, causing a multitude of variations. The ovary, through which all impulses to the genital tract are transmitted, or in which they originate, is a compound organ (like the hypophysis or adrenal) made up of at least two (follicle apparatus, corpus luteum) or perhaps three (interstitial gland) components. Of these components, the follicle apparatus (and perhaps the interstitial gland) controls the growth and nutrition of the genitals, the corpus luteum controlling the periodicity and production of the cyclical changes. The local pregnancy changes are probably accounted for by the persistence of the corpus luteum, but that the products of conception, which surely cause the persistence of the yellow body, may share in causing both the local and systemic phenomena accompanying pregnancy.

Genital hypofunction manifests itself clinically chiefly as follows: a. Anatomically; locally, by aplasia of the genitals, systemically by the signs of infantilism, eunuchoidism, and other variations depending on the time of onset and the other ductless glands most affected. b. Symptomatically; by scant or infrequent menstruation, amenorrhea, dysmenorrhea and sterility. The genital hyperfunction manifests itself clinically chiefly as follows: a. Anatomically; locally, no change, "metritic type," fibroids (?); systemically, often no change. b. Symptomatically, by too profuse, too prolonged, or too frequent menstruation; occasionally, by overfertility.

133. **Bone Transplantation in Fractures of Spine.**—As the result of a trauma Palmer's patient sustained a laceration of the supra- and infraspinous ligaments between the eleventh and twelfth dorsal and first and second lumbar vertebra. Both lamina of the twelfth dorsal were completely fractured and displaced inward, pressing on the cord, so all that was necessary to expose the cord was to dissect the soft tissues from the spinous process and lift the bony fragment from its bed. The right lamina of the first lumbar vertebra was fractured. Removal of the bony fragment of the twelfth dorsal revealed a cord compressed by angulation of the spinal canal at the junction of the twelfth dorsal and first lumbar vertebra. The cord compression was relieved by a laminectomy on the first lumbar. The cord soon regained its normal fullness and appeared uninjured.

Three weeks after the laminectomy two spinous processes above the injured vertebra and two below were exposed. The supraspinous and infraspinous ligaments over and between the two processes above, and then those of the two processes below, were cut through and separated from the tips of the spines. The supraspinous ligament over the injured vertebra was cut through and the muscle separated to make a bed for the transplant. Six and one-half inches by 1 inch by ¾ inch, with periosteum and marrow-substance removed from the crest of the right tibia. Recovery was uneventful. The patient left the hospital twelve weeks after the injury, able to stand alone and walk with assistance. Since the fifteenth week she has walked freely without assistance and has improved steadily.

139. **Controlling Hemorrhage Following Suprapubic Prostatectomy.**—The following is Hagner's method of application: A specially constructed sound with beveled end is passed into the urethra and out through the suprapubic wound; the tube attached to the bag is threaded over the beveled end and the sound withdrawn through the urethra, the tubing being pulled through and the bag pulled into place by traction on the tube. The bag is then distended with air by Janet's syringe, the pressure within the bag being readily discernible by the back pressure on the syringe. To help hold the bag in place, Hagner has wrapped gauze around the tube in cases in which it comes in contact with the end of the penis; however, the cut-off muscle tends to shut down on the tube and hold the bag in position.

140. **Operation for Suppurative Appendicitis.**—White believes that the routine ligation of the deep epigastric in drainage cases when the incision approaches the vessel will reduce the morbidity and mortality of the surgical treatment of appendicitis.

5 *Plastic Roentgen Ray Proof Preparation of Use in Roentgen Therapy. E. P. Cumberbatch.

5. **Plastic Roentgen-Ray Preparation of Use in Roentgen Therapy.**—The following formula, Cumberbatch says, is opaque to the Roentgen rays, it can be easily moulded, and it does not adhere to the patient's skin. A sample which was made twenty-two months ago has retained its plasticity to the present day. The preparation is composed of:

Bees' wax	1	parts by weight
Vaseline	1	
Resin (finely powdered)	¼	
Lanolin (hydrous)	½	
Lead oxid (litharge), finely powdered	6	

The first four ingredients must be melted on a boiling water-bath, in the order given, and each must be completely melted before the next is added. Then the finely powdered litharge is added, little by little, stirring all the time. When all is added, the vessel is removed from the water-bath and allowed to cool. Stirring must be continued till the mixture become viscid, otherwise the heavy litharge will sink to the bottom of the vessel and the preparation will have an uneven consistency. Immediately after it has solidified it tends to adhere to the skin of the operator when it is moulded, but the preparation improves greatly after a few days, especially if it is occasionally moulded. A layer about 1 millimeter thick appears to be perfectly opaque to the Roentgen rays when placed under a screen between it and the source of the rays, and the outlines of a piece of lead ⅛ inch thick are not discernible. Cumberbatch has found the preparation useful in the Roentgen-ray treatment of rodent ulcers of the lower lid, and for a case of keloid of curious shape situated over the side of the face.

14 Aneurysm of Aorta Due to Bacterial Infection. J. M. Morgan and J. H. Teacher.

12. **Presence and Significance of Nitrites in Urine.**—Cruickshank and Moyes are of opinion that the most common cause of nitrituria is an associated urinary infection, and that the presence of bacilluria should be sought for in all cases. The organisms generally belong to the *B. coli* group and possess in marked degree the power to split the nitrate of urine into nitrite. The test for nitrite in the urine affords a simple and fairly reliable method of detecting cases of urinary infection without the use of microscope, provided that

the infection is not of such degree as to render the urine markedly alkaline.

13. **Hemic Infections of Urine.**—In fifteen recent cases of typhus occurring in Ireland, Hort made films from the fresh blood, and obtained cultures from which he was able to identify the large so-called diplococcal and diplobacillary organisms which various observers have regarded as the causal agents of the disease. He has found that injections of the cultures of these organisms in citrated human blood, in which growth is easily obtained, has in no case produced any observable pathogenic effects in bonnet monkeys. He concludes, therefore, that these large organisms are not themselves responsible for the production of the disease.

In thirty cases of typhus Hort examined the urine by immediate examination of fresh specimens and by cultivation. In the great majority the fresh urine during the period of fever was turbid from the presence of micro-organisms. Both in catheter specimens in the two sexes and in non-catheter specimens the bacteriologic findings in films made from the fresh centrifuged urine were strikingly similar. In all the urines examined before the crisis great numbers of large coccal and bacillary organisms, morphologically similar to those found in the blood, were observed, and their identity was later established in the ordinary way. In each case there were also present in the deposits of the fresh urine minute organisms which occurred singly, or in pairs or in clusters. When in clusters, as well as when occurring free, they were sometimes coccal in form, sometimes bacillary, and often it was impossible to determine whether they were the one or the other. They were both Gram-positive and Gram-negative in the same clusters, they had no apparent capsules, and they were non-motile. They varied in size from about 0.1 or 0.2 micron to about 0.5 micron in their greatest diameters when in pairs, and when single their greatest diameter was proportionately smaller. They rapidly disappeared from the urine when this was incubated, and after a few hours the larger coccobacillary forms only could be found, and these readily multiplied both in urine and in, or on, the ordinary laboratory mediums. Injection of these cultures into bonnet monkeys produced no apparent pathologic effect.

After filtration of the urine through tested Berkefeld candles Hort was able in many cases to show, by immediate examination of the filtrate, the small coccobacillary forms freed from admixture with the larger non-pathogenic organisms. When, however, the filtrate was incubated, they quickly disappeared, their place being taken by the large coccal and bacillary organisms, which also proved on injection into bonnet monkeys, to be non-pathogenic. The fresh urine of bonnet monkeys successfully inoculated with human typhus blood contained, during the period of fever, great numbers of the small and large coccobacillary forms, and the filtrate of this urine, when fresh, also contained the smaller forms alone. If, however, incubation were allowed for a few hours, they could no longer be found, their place being again taken by the large non-pathogenic forms.

By inoculation of human blood-agar with the fresh filtrate of fresh human typhus urine Hort has been able to obtain cultures of the small coccobacillus in which the small size is retained. On subculture, however, it tends to become mixed with larger forms. Injections of the first culture on human blood-agar into two bonnet monkeys gave rise to a high continued fever after the lapse of a definite incubation period of a few days. From fresh human typhus blood, and from fresh cerebrospinal fluid, Hort has been able to cultivate the small coccobacillus on human blood-agar, as in the case of fresh urine. On injection of the blood and cerebrospinal cultures on blood-agar the procedure has, in bonnet monkeys, been followed by high fever after a well-marked latent period.

15. **Etiology of Eclampsia and Albuminuria.**—That eclampsia and the albuminuria of pregnancy are due to the liberation of the products of early autolysis of the placenta, Young says, has been established by the following considerations: (1) The toxemias are especially associated with recent infarction of the placenta. (2) Placental infarction is due to an interference with the maternal blood supply of the part. (3) The interference with the blood supply, which is responsible for the infarction, is not dependent on a toxic state and in point of fact may occur in the most extreme form, in which there is no evidence of a toxemia, namely, accidental hemorrhage. (4) The placenta is so constructed that, if a part of it dies, the products liberated from the dying patch can pass directly into the blood-stream. (5) In cases in which the placental disease is gradual in its onset there is more chance of the evolution of the infarcted patches. This explains why, in long-standing albuminuria, there may be more visible placental disease than in an acute eclampsia. It is just the gradual development of the toxemia that allows of the pregnancy continuing. (6) These facts all suggest that the toxemias are due to the autolytic products liberated in the early stages of the placental death.

By imitating the process, which occurs *in utero*, it has been possible to isolate from the healthy placenta a material or materials of a soluble kind which reproduce the clinical features and morbid changes, which all agree are especially characteristic of eclampsia. These are (a) convulsions; (b) peripheral focal necrosis in the liver, and (c) degenerative lesions in the kidney, especially located in the convoluted tubules. Young urges making a thorough exploration of the uterus in all cases of post partum eclampsia for a small piece of retained placenta, for a comparatively small piece may suffice to liberate fatal poisons.

16. **Anterior Colporrhaphy.**—The steps of the Fothergill operation by the new method are as follows: 1. Dilate the cervix. 2. Pick up four points, one just behind the urethral orifice, one at the junction of the cervix and the posterior vaginal wall, and one on either side of the cervix, about an inch to right and to left of the cervicovaginal junction. 3. Connect the four points by an incision through the vaginal wall. 4. Begin at the urethral angle of the incision and separate the area of vaginal wall enclosed by the incision from the bladder and the other adjacent structures until it remains attached only to the cervix. 5. Snip round and round the cervix until a sufficient portion of the latter is exposed. 6. Cut through the cervix without splitting it. 7. Stitch the stump of the cervix into the posterior angle of the wound, working from behind forward, and placing the sutures so that they radiate round the new os uteri. 8. Close the remainder of the incision from side to side.

34. **Rheumatic Infection.**—The author's analysis is based on 350 fatal cases of rheumatism. There were 195 females and 155 males in this series. In 100 consecutive cases there was a strong family history in 26. In 250 cases under 12, 59 died in what were apparently first attacks, and four more were doubtful. In 100 cases over 12, only 3 deaths were recorded in a first attack, and 2 of these were practically children, being both 13 years of age. One case, a young woman of 21, died in a first attack of acute carditis. With few exceptions, the fatal issue was the result of cardiac disease and its complications. In 250 cases under 12 the pericardium was affected in 215. In 250 cases the mitral valve was only reported undamaged in 3; the aortic valve in 102 cases; the tricuspid in 78 cases; the pulmonary valve in 6 cases. In this series, there were 102 examples of combined aortic and mitral lesion. An analysis of the cardiac lesions in patients over 12 years showed that 22 died of malignant endocarditis; 29 died of mitral stenosis; 20 died of mitral and aortic disease of the simple form; 15 died of double mitral disease; 9 died of acute carditis—characteristic of childhood; 1 died, without a valvular lesion, from a dilated heart and external pericardial adhesions at the age of 16.

There were 30 cases of malignant endocarditis. In 14 of the 30 cases there seemed to be a decided relation between the rheumatism and malignant endocarditis. From a study of this series it was apparent that arthritis, pericarditis, nodules and other manifestations of a rheumatic type, may occur during the final illness, and may actually be recovered from. In only 3 of the 350 cases was there no valvular lesions and death from myocardial failure. One was acute, the other 2 were chronic. Pleurisy and mediastinitis in a series of 100 cases were present in 50 per cent. Two cases demanded paracentesis. Congestion and basal edema, with brown induration in some cases was present in at least 38 out of 100 cases. There were two examples of acute edema of the lungs in 100 cases. Bronchopneumonia occurred in 12 per cent. of these cases. Infarctions were present in 11 per cent.; peritonitis in 5 cases; ascites occurred in 10. Thrombosis of branches of the portal vein occurred in one instance, and hemorrhages into the mucous membrane of the stomach also in one instance. Thrombosis of one or more of the large veins in the neck occurred in three cases.

35. **Carcinoma of Stomach.**—Sherren urges that every suspicious case should be considered surgically, and that cases of chronic gastric ulcer should be submitted to surgical treatment early. In this way the percentage of "cures" will be much improved and the incidence of the disease greatly lessened.

48 *Gonorrheal Arthritis. O. M. Chiari.
49 Etiology of Gastric Ulcer. R. Vogel.

47. **The Roentgen Method of Examining the Kidneys.**—Altschul gives an alphabetical list of 604 articles on this subject and compares the views of the different authors. He expatiates on the extreme importance of the Roentgen findings not only with calculi and displacement of the kidney but in hydronephrosis and pyonephrosis. The Roentgen method with a tumor or tuberculous process in the kidney is less instructive than other methods of clinical examination, as a rule. "A reliable Ronetgen picture of the kidney should show the edge of the psoas, the transverse processes of the vertebrae and the last rib. The edge of the psoas does not encroach on the kidney shadow in normal condition. Kidney calculi cast a shadow so that negative findings exclude a concrement with 97 per cent. certainty." Even in the apparently negative cases the concrement may show up if a silver salt is injected into the pelvis and then withdrawn. Enough of the silver salt clings to the concrement to render it visible then.

In case of positive findings the various sources of error must be excluded. He lists forty-eight possible sources of error, including fruit stones, gall-stones and concrements in the bowel or prostate, cheesy or calcareous processes, scars in the kidney, relics of bismuth in the bowel or of iodipin possibly decades after intramuscular injection, warts on the back, undissolved pills, salol, fragment of broken spinous process, calcified parasites in muscle tissue, hypernephroma, deposits of sulphur, etc.—he cites one or more clinical instances of each. Even the most expert are liable to draw mistaken conclusions at times, as when the opaque catheter passed smoothly along past a suspicious shadow in the ureter, and it proved to be a ureter stone lodged in a diverticulum. The diagnosis of kidney stones used to be made too lightly and too frequently.

48. **Gonorrheal Arthritis.**—Chiari reviews 470 articles published on this subject in the last ten years. Gonococci are seldom found in the effusion in the joint after the acute stage is past, except in the more malignant types with involvement of the myocardium. He tabulates 443 cases in which vaccine therapy was applied with autogenous or commercial vaccine. Only forty-two cases were uninfluenced; thirty-two patients were improved and 367 cured. In 16 cases antimeningococcus serum was used instead of a vaccine, and 13 of the patients were cured. Ramond reported in 1911 successful autoserotherapy in 5 severe suppurating cases; he injected several times from 1 to 5 c.c. of the fluid obtained by puncturing the joint. The injection was made subcutaneously near the joint in question. Maillet has reported similar experiences, as also Constantinescu with hydrarthrosis. The progress in the last decade has been such that we can count now on curing the arthritis with vaccine therapy and physical measures, especially stasis hyperemia and superheated air, or at least inducing marked improvement even in apparently desperate cases.

50. **Serotherapy of Tetanus.**—Behring calls attention to the fact that the symptoms of tetanus are the result of the action of the tetanus toxin on the central nervous system and especially on the motor ganglion cells. The tetanus toxin reaches the spinal cord only by way of the nerves, on account of its special affinity for nerve tissue. Research has demonstrated further that the toxin makes its way up the nerve tissue quite slowly. One consequence of this is that the longer the nerve tract, the longer the period before the characteristic symptoms develop. It takes five days in the horse, one or two days in the dog, thirteen to eighteen hours in guinea-pigs, and only eight to twelve hours in mice. The local focus should be excised and antitetanus serum be given to neutralize the still free toxin, and the passage of the toxin up through the nerve tissue interrupted by resection of the nerve. It is useless, he says, to amputate the whole limb when all that is needed is to make a gap in the nerve running to the focus of infection. His collaborator for twenty-five years, "H. S.," has on three occasions accidentally infected himself with tetanus by the breaking of a glass vessel. The third time (1902) the cramps of the shoulder, chin and eyelids and bad general symptoms following the breaking of a tetanus culture tube in his hand all subsided after the trunk nerves were exposed in the axilla and an injection of the strongest antitetanus toxin made into each. The tetanus was arrested and gradually retrogressed to complete recovery. The use of the arm was restricted for a time but was finally regained in full. In prophylaxis, Behring thinks that wounds with bad smelling secretions had better be treated with iodoform in coarse crystals while those of benign aspect should be irrigated with a 0.1 or 0.5 per cent. solution of iodin trichlorid. Preventive antitetanus serum may merely postpone the tetanus which may develop as soon as the effect of the serum has worn off. Consequently it may be well to make a second injection with an antitetanus serum designed to avoid danger of anaphylaxis.

56. **Dental Protheses for the Wounded.**—Dieck insists that the teeth of the soldiers should be put in good condition before they are sent to the front. All broken-off roots should be pulled even if they are not causing disturbance. The tissues around are seldom quite normal and although there is no trouble under ordinary conditions, chilling, wetting and trauma are liable to set up mischief in the old prongs at any moment. In fact he goes back of the reservist to the children, and emphasizes the necessity of systematic training and dentistry of the children in school as a vital factor in building up the health of the rising generation and reducing dental trouble in the land and sea forces. Dental protheses are of the greatest importance in case of wounds of the jaw, as fracture of the jaw is of more vital consequence, he declares, than fracture of any other bone, perhaps. The Japanese army was supplied with ready-made adjustable splints for fractured jaws, and they restored the functional use of the jaw.

57. **Blood Platelets Responsible for Anaphylactic Intoxication.**—Behring reviews here the intensive research in regard to anaphylaxis which has been conducted during the last four years at the institute at Marburg in his charge. The results confirm the assumption that the blood platelets are responsible for anaphylactic shock. Some disturbance in the medium or in themselves causes them to clump, and the consequence is obstruction of the smallest blood vessels with the clumped platelets. This in the brain brings on anaphylactic shock. It is more than a mere coincidence that all substances which induce anaphylactic shock in normal, nonsensitized guinea-pigs have a destructive action on the blood platelets, both in the test-tube and in the living body. The history of this view and the various data which have led up to it are analyzed and the practical result stated that he has succeeded in making an extremely powerful agglutinating substance out of the blood platelets; it is capable of coagulating a mixture of fibrinogen, etc., with one part to forty million parts of the mixture. He suggests that the platelets should more properly be called "thrombocytes."

63. **Traumatic Softening After Fracture of the Semilunar Bone.**—Gaza has recently encountered two cases of this rare affection of the semilunar bone of the hand. In both the Roentgen rays threw the first light on the clinical picture. Comparison with similar cases on record shows that the so-called traumatic softening is in reality a fracture, generally in the middle of the crescent and it is shown up instructively by the Roentgen rays only when they are applied in the radio-ulnar direction. Patches of lighter shadows are seen as the result of destruction at the time of the fracture or of absorption or abnormal deposits of lime. Later the bone may develop serious secondary changes such as occur in spongy bones elsewhere, the tardy result of injury, as, for example, in traumatic coxa vara, in Kümmell's kyphosis of the spine, after fracture of the heel, and possibly after Köhler's affection of the scaphoid bone of the foot. There may be a latent period of months or years after this semilunar bone fracture, and then the joint may develop a severe secondary arthritis and the only means of relief be removal of bones in the wrist with eventual interposition of a flap of fat in the gap left in the set of carpal bones.

66. **Prophylaxis of Epidemic Disease.**—In the course of these general remarks Nocht emphasizes the danger of transmission of disease by flies, saying that typhoid and dysentery seem to have a special attraction for flies. The English noted in their southern Africa campaign that when men with typhoid and with other affections lay in the tents, the flies collected on the typhoid cases and left the others in peace. He tells the story of a guest at a North Sea health resort who complained to the hotel proprietor of the hosts of flies in the privies, and was told, "You had better plan to go to the privy during meal-hours as the flies are all in the dining-room then." Nocht states that lime has not proved effectual for sterilizing manure, and a 25 per cent. solution of commercial ferrous sulphate seems the best disinfectant for this purpose.

67. **Tetanus.**—Jackobsthal remarks that the greater prevalence of tetanus among the wounded now in comparison to previous compaigns may be due to the more conservative treatment and to the digging of and fighting from trenches. The tetanus does not attack always the most severely wounded but only those with ugly, jagged wounds. He urges prophylactic injection of antitetanus serum on the firing line in cases of such wounds or all wounds soiled with dirt. The supply of antitetanus serum in Germany will not permit this at present, and he insists that more should be made at as many points as possible. "Even small private laboratories can make a satisfactory antitetanus serum that will answer for prompt prophylaxis, and horses should be supplied them for the purpose." He adds that he found tetanus germs in three out of seven specimens of the Indian fibers, *pengawar djambi*, which are sometimes used for dressing wounds. He examined this substance bacteriologically after knowing of

two cases of tetanus that had developed in patients whose deep wounds had been staunched with these fibers.

Therapie der Gegenwart, Berlin

October, LV, No. 10, pp. 409-428

72 *Epidemic Diseases during Wartime. (Kriegsseuchen.) L. Dunner.
73 *Synthesis of a Nucleic Acid. (Emil Fischers Synthese einer Nucleinsäure.) G. Klemperer.

72. **War and Pestilence.**—This article is a summary of a series of five postgraduate lectures on the diseases liable to become epidemic during the war. Kirchner emphasized the danger now from the lack of the previously enforced international exchange of information as to appearance and spread of epidemic diseases in other countries. Now we have merely rumors instead of accurate information as to the points in which the danger threatens. While the wounded are sent back to the home zone as rapidly as transportation can be secured, soldiers with an epidemic disease should be kept on the spot and not be despatched to the rear or the home zone. Isolation shelters can be erected almost anywhere, and provision made nearby for a sterilizing plant. The disposal of the dead and of dead horses is a problem that has not yet been satisfactorily solved. He advises to wait before vaccinating against cholera until cases of the disease actually occur as the immunity conferred is of brief duration. "The production of antiplague serum is a difficult and dangerous matter as the horses have to be inoculated with living cultures, and several of the workers in this line at Petrograd have lost their lives at the work." He adds that antidysentery serum is ineffectual in certain forms of the disease.

73. **E. Fischer's Synthesis of a Nucleic Acid.**—Klemperer states that the year 1914 will be memorable in science on account of the announcement of E. Fischer at the July meeting of the Prussian Academy of Sciences that he had succeeded in synthetically producing cell-nucleus substance. It is in the form of a theophyllin-glucosid phosphoric acid which crystallizes readily and is apparently a uniform chemical entity. The process is extremely simple, namely, by the use of dry pyridin and phosphorus oxychlorid, as is described in detail, as also the various properties of the synthetic nuclein. Fisher remarked, "The successful research in this line opens the way for synthetic production of many substances more or less closely analogous to the natural nucleic acids. How will they act on the living organism? Will they be directly assimilated and used in building up the cell nucleus or will the living organism reject them or break them down before assimilating them? Experimental research alone can answer these questions. I am audacious enough to hope that under especially favorable circumstances the assimilation of artificial nucleic acids can proceed without the splitting of the molecule. This, however, must lead to profound changes in the organism, changes which possibly may resemble those permanent ones observed in natural conditions, which we designate as mutations." Klemperer remarks in conclusion that the cooperation of synthetic chemistry with experimental biology may lead to new therapeutic achievements, especially in the treatment of gout, just as the treatment of diabetes was placed on a sounder basis by the discoveries which resulted in the synthesis of carbohydrates.

74 Diathermia in Gynecologic Disease. J. Kowarschik and H. Keitler.
75 *Parotitis in Barracks. (Mumpsepidemie 1913-1914 in der Garnison Graz.) W. Kulka and A. Neumann.
76 Notifiable Diseases in Vienna. (Die anzeigepflichtigen Infektionkrankheiten Wiens in den Jahren 1901-1910.) S. Rosenfeld.

75. **Mumps in a Garrison.**—Kulka and Neumann state that 293 of the 317 cases last year in the barracks at Graz were in one regiment while only a few scattered cases developed among the other troops although in close contact with them. Droplet infection is incriminated and convincing instances are related to prove this and also that direct transmission and the entire period of incubation can be comprised in twenty-four hours. In several cases, after an interval of from fifteen to seventy-five days, there was a new attack of the mumps or relapse. Orchitis developed in only 13 per cent.

October 17, No. 42, pp. 1585-1608

81 *Symptoms and Treatment of Fractured Patella. Haeberlin.

77. **Diagnosis of Appendicitis.**—Ten Horn found in twelve of the fifteen cases of appendicitis that traction on the right spermatic cord, seized just above the testicle, caused sharp pain. Pulling on the cord evidently drags on the parietal peritoneum at the internal inguinal ring and if there is inflammation this causes pain. The cremaster reflex is not to be relied on as a sign of appendicitis.

78. **Resection of the Stomach.**—Neugebauer expatiates on the advantages of Reichel's method of suturing the stomach directly to the jejunum after circular resection. He has applied the method in twenty cases with constant satisfaction, but instead of trying to join the entire cut surface of the stomach to the jejunum he sutures the upper two-thirds to close the stomach like a bag, and joins merely the lower third of the stomach stump to the jejunum. The stomach thus forms a wide bag tapering toward the wide opening in the bottom directly into the jejunum. By this method it is possible to resect even quite high ulcers on the lesser curvature, and yet have a broad enough base to the bag to join to the jejunum with an ample outlet for the stomach, as he shows in an illustration.

79. **Permanent Cure of Presternal Dislocation of the Clavicle.**—Danielsen quotes authorities to confirm his own experience that this form of luxation is easily diagnosed and reduced but that it is extremely difficult to keep it reduced, and pain and disturbed function inevitably follow. He declares that the principle of the usual method of correction by drawing back the shoulder is wrong. The shoulder should be drawn forward, not back. He applied this principle in a recent case with prompt and permanent cure of the trouble. To hold the shoulder in this forward position he lifted the arm and bandaged it so that the upper arm lay against the cheek, the forearm on top of the head.

81. **Diagnosis and Treatment of Fracture of the Patella.**—Haeberlin's experience in a recent case confirms in every respect the importance of Dreyer's sign of intact muscle apparatus with fracture of the patella. (It was described in The Journal, July 11, 1914, p. 206.) By excluding the action of the quadriceps by applying extension to the thigh, we can see at once whether the muscle is lacerated along with the patella. In the case reported the patella was fractured in falling from a wagon and the gap was almost one and a half fingerbreadths. The man was unable to extend his leg or raise it when passively stretched, even after an extension bandage had been applied to the thigh, thus confirming the assumption that the muscular apparatus had been torn across also. The operation revealed that this was the case in fact, but rapid recovery followed under extension and Kausch suspension.

85 Anatomy and Pathology of the Menstruation Cycle. R. Schröder.
86 The Stem Pessary. (Zur Frage der Intrauterinstifte.) A. Goenner.

82. **Gynecology and Obstetrics in Tropical Africa.**—Deppe's district has the reputation of being one of the unhealthiest on the east coast; he found malaria parasites in the blood in 44.2 per cent. of 988 healthy natives examined last February. The total mortality among the 19,629 whites for this period was 2.4 per cent., namely, men, 2.8; women, 1.6, and children, 2.6 per cent. Of this total mortality 50.2 per cent. was due to tropical diseases. He comments on the importance of capable, healthy white women for the welfare of a tropical colony, as on them usually depends the efficiency of measures to protect against infected mosquitoes, contaminated drinking water and improper food and clothing. Sex does not seem to affect the liability to malaria, and evidence is accumulating that this applies also to climatic influences. Pregnancy seems to be carried a little past term, as a rule; labor is short and delivery easy, but Deppe's experience has been that an obstetric case requires closer supervision in the tropics than elsewhere. The fetal membranes rupture early and the unfavorable conditions in the tropics in regard to radiation of heat are liable to render the nervous system unstable. The physical cause should be sought; this may be the hyperemia of the abdominal organs, which is physiologic for the tropics. In conclusion he reiterates the importance of regular exercise for both men and women as this alone keeps the body at par in the tropics as well as elsewhere.

84. **Asthenia-Enteroptosis.**—Kaiser gives a historical review of the varying conceptions in regard to whether the viscera are suspended by their supports, "like clothes in a wardrobe," or whether "the ligaments merely determine their relative position while the abdominal pressure bears their weight" or whether they rest on organs and tissues below as on a cushion and would stay in place even if all their ligaments were severed. The surgeons and internists are still disputing on the subject, Rovsing pointing to his successful operations to suspend the organs better, while Faber claims that asthenia-enteroptosis should be combated by general internal medicine. Kaiser's view is that the internal conception is nearer the truth, but as it so seldom is systematically applied to bear fruit, surgical measures are more practical and are usually successful. In some cases there is undoubtedly a disproportion between an unusually large abdominal cavity and unusually small viscera. The heaviest viscera sink down the lowest, he adds, citing Mann's case in which the liver contained an abnormally high proportion of iron, and had sagged exceptionally low.

93 Lactose Content of Human Milk. (Concentrazione del lattosio nel latte di donna.) E. Palmegiani.
94 *Splenic Anemia in Children. (Etiologia e patogenesi dell'anemia splenica nell'infanzia.) G. Caronia.

91. **Chloroma in a Child.**—Di Cristina's little patient died the fifth month after the first sign of trouble, a tumor in the right orbit. Severe pains in the bones soon followed and necropsy showed that all the blood-producing organs had been involved in the pathologic process. The mother was tuberculous and the child gave a positive Wassermann reaction but there was no response to tentative specific treatment and there was nothing else to suggest syphilis in the child or family so that the reaction was most probably non-specific in this case. The blood findings resembled those of acute leukemia.

92. **Chronic Hydrocephalus and Inherited Syphilis.**—Cannata obtained a positive Wassermann reaction in only 10 of the 19 infants with chronic hydrocephalus he encountered last year, but application of the test to the parents gave positive results in 16 of the mothers and in 4 of the 10 fathers tested. One child and its mother gave a negative reaction but the father responded positively. In an additional group of 3 cases of chronic hydrocephalus the test was not applied as the parents were unmistakably syphilitic. These findings justify prompt treatment for inherited syphilis in every case of chronic hydrocephalus without waiting for the assumption of syphilis to be confirmed.

94. **Splenic Anemia in Children.**—Caronia has applied the Wassermann test systematically to the parents of the 30 children with splenic anemia in his service during the last twelve months. He obtained a positive response in 19 cases. The syphilis in the family was accompanied by tuberculosis in 9 cases; in 2 there was tuberculosis in the family without detectable syphilis. His experience confirms the assumption that still other causes may bring on splenic anemia in children. Chief among these probably is sepsis with a chronic course.

109 Behavior of Cerebrospinal Fluid in Acute Nephritis in Children. L. M. Spolverini.

95. **Workmen's Compensation.**—Diez is medical inspector of all the Italian railroads and has extensive experience with accidents among the employees and determining the pensions for disability. He reviews the various systems in vogue for this in different countries and discusses in particular the best means for stimulating a crippled workman to make the most of what functional capacity he has left. When he is assured of an indemnity proportional to the injury, he is interested in exaggerating his crippled condition instead of trying to overcome it. Diez expatiates on the necessity for institutions to train the crippled to overcome their handicap. Resumption of work is in itself, he says, a powerful aid in the cure for the majority of industrial accidents while loafing aggravates the functional weakness and increases the psychic incapacity

for work. He thinks the best plan is an indemnity for two or three years on a declining scale, to be forfeited unless the workman makes every effort to improve his functional capacity under proper training. The man knows that at the end of this period he will be left without income from this source, and hence he will have every inducement to become self-supporting in the interim. Unforeseen complications or errors in diagnosis may call for revision, but otherwise this plan—which is already working well in Switzerland for traumatic neuroses—seems very promising, he thinks.

100. **Dilatation of Uterine Cervix for Dysmenorrhea and Sterility.**—Zekete writes from Budapest to laud the fine results to be obtained by systematic mechanical dilatation in cases of stenosis, deformity or obstruction from any cause of the lumen of the uterine cervix. In eighteen cases the women had never conceived and menstruation was more or less painful. In six of the cases the mucosa showed signs of chronic inflammation or hypertrophy. The mucosa was curetted and touched with tincture of iodin and the intracervical stem pessary introduced and held in place by packing with gauze which was changed each day, inspecting each time to see that the instrument was in place. The patient stays in bed for eight days and continues to wear the endouterine pessary for twenty days in all. It was removed and cleansed two or three times and never caused the least disturbance of any kind. In the 20 cases treated for dysmenorrhea, complete success was realized in 16, the cervix becoming of normal size and shape and no longer opposing any obstacle to the menstrual flow, and in the others the former extremely severe dysmenorrhea has been very much improved. This systematic method of treatment corrects infantile conditions and anteflexion or both. In some cases the dysmenorrhea did not develop until after marriage.

102. **Foci of Inherited Syphilis in Rome Province.**—Campana states that in his expeditions into the rural districts to help in rooting out malaria he has frequently had groups of children brought to him for treatment of malaria who showed unmistakable signs of inherited syphilis. The promiscuous family habits and the custom of hiring out as wet-nurses have contributed to the spread of syphilis in the province. He cites a number of typical cases to emphasize the differential points and urges the necessity for specific treatment in addition to the treatment for malaria. He found signs of incipient myocarditis quite pronounced in a number, and the teeth were exceptionally fragile and malshaped even when they were not of the typical Hutchinson shape.

110. **Endemic Goiterism.**—This is a free translation of Grassi's term *gozzismo* by which he designates the syndrome affecting persons in certain districts, the chief seat of the trouble being apparently in the thyroid gland, and the manifestations running a wide range of morbid conditions, chief among which are goiter, cretinism and deafmutism. He reviews the various theories in regard to the etiology, summing up his own view in the statement that there is no conclusive evidence to date that incriminates infection, contagion nor the drinking water. There may be multiple causes at work, he thinks, inadequate nourishment and ventilation, much contaminated waters and damp and dark houses. He lists the literature on the subject that has appeared in the last ten years.

116. **Phonoauscultation.**—Pletneff applies this term to auscultation with a tuning-fork and stethoscope or phonendoscope. The tuning-fork is placed over the organ to be examined, and its vibrations are listened to through a stethoscope or phonendoscope placed on the same organ. The tuning-fork is gradually moved along from the neighboring organs to the one to be examined, and when it reaches the latter an increased and louder resonance is perceived. With this method the stomach boundaries can be easily differentiated from those of the intestines, the boundaries of the lungs can easily be determined, also foci of infiltration in the lungs. Pleuritic effusions, etc., change the resonance. It can be used not only to outline different organs but also to distinguish diseased conditions in them.

117. **Elimination of Iodin by Healthy and Diseased Kidneys.**—Sivert and Kaminsky report that six healthy persons were examined and it was found that healthy people rapidly eliminate iodin, the average proportion being 77.9 per cent. of the total amount during the first twenty-four hours. During the second twenty-four hours the amount of iodin eliminated is from 15.5 to 19.6 per cent. of the dose taken, while during the next twenty-four hours the elimination of iodin stops altogether. Only about 5 or 6 per cent. of iodin remains in the body, or is eliminated by other organs. The elimination does not seem to depend on the amount of urine voided. In the patients with pathologic kidneys examined there were 5 with acute and 2 with chronic parenchymatous nephritis, and 4 with chronic interstitial nephritis. In parenchymatous nephritis the elimination of iodin by the kidneys is rapid and complete, the average proportion being 81.9 per cent. of the amount taken. Of this amount 70 per cent. is eliminated during the first twenty-four hours. No difference was noted in this respect between acute and chronic parenchymatous nephritis which thus resemble healthy kidneys in regard to the amount of iodin eliminated. In 4 cases of chronic interstitial nephritis the amount of eliminated iodin is markedly decreased, being 17 per cent. instead of the normal 70 or 80 per cent. The duration of the iodin elimination is considerably prolonged, sometimes for five or six days. The test dose was in all cases 1 gm. of potassium iodid given after a meal. The authors think that the nature of the renal trouble can thus be determined from the proportion of iodin eliminated. If this is below 70 per cent. it indicates an interstitial process.

119. **Ligation of the Inferior Thyroid Artery for Strumectomy.**—Petroff warmly recommends De Quervain's method of ligating the inferior thyroid artery before operating on the thyroid gland. This renders the subsequent course of the operation comparatively bloodless. Petroff used this method on fourteen patients in one year—all under local anesthesia plus epinephrin. Ten minutes was sufficient to find and ligate the inferior thyroid artery. Once he was unable to locate it. The strumectomy was done when the upper thyroid was also ligated. The inferior artery is ligated only on one side, as bilateral ligation might endanger the nutrition of the parathyroids. Complete recovery was the rule in from six to thirteen days.

122. **Tubercle Bacilli in the Blood in Incipient Tuberculosis.**—Lopatin found tubercle bacilli in the blood of only 6 of 26 patients in the initial stage of tuberculosis or only suspected of this, but there were numerous acid-proof bacilliform formations that could be easily mistaken for real tubercle bacilli. Positive results from inoculation of guinea-pigs were obtained in 9 cases out of 16 that showed signs of initial tuberculosis. Of 10 patients that did not show clinical signs of tuberculosis, only in 2 cases could tuberculosis be demonstrated in the guinea-pigs. This method is reliable provided the tissues of the animals show characteristic changes. Bacillemia thus occurs in about 60 per cent. of patients in the initial stage of tuberculosis.

123. **Salvarsan in Surgical Syphilitic Lesions.**—Ivashenzoff and Lange treated with salvarsan and neosalvarsan sixty patients with gummatous syphilis of nose, throat, pharynx, larynx, skull (2 cases), tibia, penis, sternum, joints (tabes), syphilitic osteomyelitis or periostitis. The doses for salvarsan were 0.5 to 0.6 gm. for weekly intravenous injections, followed sometimes the next day by an intramuscular injection of 0.4 to 0.5 gm. The dose for neosalvarsan was 0.75 to 0.9 gm. Sometimes the patients felt much improved from one to two injections, especially with lesions of the nasopharynx or larynx. The voice that for years had been lost would clear up, and the breathing become free, rendering the use of the tracheotomy tube superfluous. The success in the treatment of nasal lesions was so striking in some cases that rhinoplastic operations could be postponed and rendered more efficacious as the tissues became stronger and more vital. The same excellent results were obtained in the rest of the above mentioned lesions. Complications are liable but with the proper technic and dosage they are comparatively rare.

124 *Operative Treatment from Without of Intralaryngeal Cancer; Thirty-Three Cases. (Resultaterne af den operative Behandling —Laryngofissur—af den intralaryngeale Cancer.) E. Schmiegelow.
125 *Operative Treatment of Diffuse Lipomas of the Neck. (Et opereret Tilfælde af Madelungs Fedthals.) E. Gjessing.

124. **Intralaryngeal Cancer.**—Schmiegelow's report on sixty-six operative cases of cancer of the larynx was presented at the Clinical Congress of Surgeons held at London last July. He emphasizes that in by far the largest proportion of cases the cancer started in the vocal cords, and that cancer of this origin is more readily and completely eradicated while it induces hoarseness almost from the start and is thus detected early. The growth besides is unusually slow. An exception to the grave prognosis with other forms of cancer of the larynx is the pedunculated adenocarcinoma growing from the superior aditus laryngis. In his total 66 laryngeal cancer cases, 5 were removed through the mouth but 4 succumbed to recurrence, 10 died from recurrence without an attempt at operation, and 8 died in the 8 cases treated by means of tracheotomy and also in the 1 case treated by subhyoid pharyngotomy, 4 by partial resection and in all but 1 of the 9 treated by total resection. In the 33 cases in which the cancer was removed by thyrotomy, 18 of the patients were cured; 5 succumbed to pneumonia and 10 to recurrence. The interval after the operation has been from ten to eighteen years in 4 cases; from three to nine years in 9 cases and two years in the others. Two of the patients died from a cancer in rectum or stomach eight and eighteen years after the operation and at the necropsy the larynx was found clinically normal. He compares these results with those reported by Semon (24 cases), Chiari (29) and Thomsen (10)—a total of 96 cases of thyrotomy technic applied to laryngeal cancer, with 61 surviving for more than a year, that is, over 63 per cent.; 9 did not long survive the operation and 25 succumbed to recurrence.

125. **Operative Treatment of Symmetrical Lipomas of the Neck.**—Gjessing's patient was a man of 50, healthy until he became addicted to liquor a few years ago. Treatment for a gastric ulcer has been required recently. The lipomatosis had been developing for sixteen years. The huge lipoma encircling the entire neck was excised at two sittings, with an eighteen-day interval, and although there was some suppuration from the wound at first the results were excellent. Removal of the lipomas is a comparatively tedious procedure but the mortality is zero. In some cases on record the cure was permanent; in others there was great relief for a long time although there was recurrence later.

126 *Treatment of Exophthalmic Goiter. (Till frågen om behandlingen av morbus Basedow och särskilt om indikationerna för operationer å glandula thyreoidea vid denna sjukdom.) K. Petren.
127 Measles in Infants; Thirty-Three Cases. (Mässling hos späda barn.) A. Lichtenstein.
128 Muscular Work from Heat and Energy Standpoint. (Om muskelarbetet från termodynamisk synpunkt.) O. Ottosson.

126. **Treatment of Exophthalmic Goiter.**—Petren discusses in particular what indications in exophthalmic goiter call for surgical treatment and comes to the conclusion that the cardiac symptoms are the criterion for this. None of the other cardinal symptoms is constant enough to base the indications on it. But the almost delirious heart action is a futile waste of energy and a source of permanent injury. The palpitation and the rest of the excessive action of the heart lead to a compensating hypertrophy and dilatation, and may finally wear out the heart from the overstimulation of the sympathetic from the hyperthyroidism. As this is the most serious element of the Basedow clinical picture, in his opinion, he bases on it the decision whether to operate or not. When the heart is already enlarged and does not subside under medical treatment or the heart symptoms show no marked improvement, an operation should be undertaken. It may also be indicated if the mental or moral nature is changed. In the majority of cases the disease is mild and subsides more or less completely under medical measures. The patient should be kept systematically in bed. The latest reports on serum treatment, especially with milk from thyroidectomized goats, have not been encouraging, but Petren himself has had occasional good results from it. He has also obtained good results from carbonated baths and electricity to the nerves in the neck. The carbonated baths had an unmistakable soothing effect on the rapid heart action. Hot and cold baths might aggravate conditions.

October 1, LXXVI, No. 40, pp. 1721-1766

129 *Potassium Iodid Test for Carbon Monoxid in the Blood. (Metode til Paavisning af Kulilte i Bloder.) K. Sand.
130 Average Food Ration in Denmark. (Danske Familiers Forbrug af de enkelte Födemidler.) M. V. Bjorum and P. Heiberg.

129. **Detection of Carbon Monoxid in the Blood.**—Sand states that when halogens are added to blood the oxyhemoglobin is transformed instantaneously into methemoglobin, and the color changes with this from red to brown. When the blood is under the influence of carbon monoxid, the hemoglobin resists the halogen and there is no change in tint. His various experiments have shown that in the form of a solution of 1 part iodin and 2 parts potassium iodid to 300 parts distilled water this inhibiting phenomenon occurs with special force. He utilizes this to detect and estimate any proportion of carbon monoxid in the blood. The iodid solution is added to a set of test-tubes containing each 10 c.c. of normal or the suspected blood, until in the control tubes all the oxyhemoglobin has been completely transformed into methemoglobin, as evidenced both by the tint and spectroscope. The same number of drops is then added to the corresponding tubes of the suspected blood. The reaction occurs down to a content of 0.25 per cent. carbon monoxid and below; 0.125 per cent. seems to be the limit. The best results were obtained with the blood diluted to 2 or 3 per cent. He says that the color reaction occurs earlier and is more distinct than with other technics, and it is four times as sensitive, revealing as little as 5 per cent. carbon monoxid content. When the blood is at a temperature of 20 C. the reaction occurs instantaneously. This technic permits also spectroscopic control with the same specimen of blood.

SERVICES TO BE EXPECTED FROM THE PSYCHANALYTIC MOVEMENT IN THE PREVENTION OF INSANITY *

JAMES J. PUTNAM, M.D.
BOSTON

I understand that the problem before us for discussion is, How can we best help people to preserve their mental health? and that my part in it is to answer the particular question, What contribution can psychanalysis make toward this end?

I shall confine my remarks almost exclusively to this one point of prevention, resisting the temptation to wander at length over the wider field of the mental treatment of patients who have actually shown distinct symptoms of one or another form of the psychoses.

It is, however, germane to say that inasmuch as psychanalysis is best definable, from the therapeutic point of view, as an educational method of high value, and since, under all circumstances, it exerts its usefulness largely through helping the patient to become a more thoughtful, more rational, and more mature person, the aims of prevention and the aims of treatment are to a great extent the same.

It is also proper to point out that the psychanalytic literature contains very encouraging reports, indicating not only that the temperamental tendency to depressive states, but even the tendency to recurrent manic-depressive outbreaks, can sometimes be affected favorably by this treatment; and that there is some evidence that patients with dementia praecox in its initial stage can occasionally be benefited in the same manner.

It is my confident belief that the contribution of the psychanalytic movement to prevention is to become an important one, but that it will make itself felt not so much directly, through the treatment of individual patients, as indirectly and gradually through the stimulus which these searching studies into the nature and history of human motives must exert on parents and educators, in proportion as the principles discovered or emphasized by them become an integral part of psychologic doctrine.

To assert that it is possible to prevent or cure a psychosis by mental influence is equivalent to asserting the psychogenic origin of these diseases. To maintain this is not to deny that special toxic influences, general disorders of metabolism, or abnormalities of cerebral structure or development may play an important part as predisposing causes, or even that the influence which these causes exert in one or another case may have been the controlling influence, *sine qua non.*

It is, however, certain that even where this is so, the mechanism of the psychosis, as a mental phenomenon and as the sign of the occurrence of a mental process having a more or less clearly definable aim and meaning, ought to be specifically studied, and that in order to do this thoroughly the physician should have made himself aware of the patient's inner life, both as an individual and as a member and representative of a social group or social groups.

The psychoses and psychoneuroses are not to be regarded (psychologically) as mere misfortunes or mere accidents, but as phenomena that represent definite, instinctive attempts at readjustment and the securing of some workable equilibrium, on the part of persons whose actual adaptation to their environmental conditions had proved unsatisfactory in the face of this or that special strain, and whose powers of readjustment had shown themselves inadequate to the task of restoring the disturbed balance in any better fashion. This view is in harmony with that of Meyer, Hoch, Bleuler and others who have stood for a partially psychogenic origin of the psychoses, and have recognized that the constitutional and temperamental make-up of each patient's personality is partially responsible for his illness, or, as I should say, for the method which he instinctively adopts to reassert himself. The psychoses form, in short, one more illustration of the general principle that illness may be classified as the manifestation of efforts toward a certain sort of health.

It is no valid argument against this view to say that the outcome of these efforts, from the clinical and social standpoint, seems anything but desirable. The "desirability" depends, as a rule, only on the satisfaction of the patient's unconscious cravings; but in this sense his illness may secure him something which, with one portion of his nature, he may be said to wish for.

There are times when, from this point of view, a fit of anger fills, psychologically, a useful purpose—then, namely, when it makes the rational thinking which the angry person does not wish to use, or cannot use, seem so impossible that no one asks him to attempt it. Similarly, when a wife's hysteria gains her the attentions of her otherwise inattentive husband, it fills, from the standpoint of her deeper longings, an important place. And the process is, for her, all the more "desirable" if it works without any conscious acquiescence on her part.

---

* Read before the Section on Nervous and Mental Diseases at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

It is believed by those who accept the explanation offered by psychanalysts[1] that the difference in mechanism between the psychoses and the psychoneuroses is one (from the psychologic standpoint) mainly of degree. Leaving wholly aside the problem of physical or chemical influences (not by any means as unimportant, but as not germane to this particular discussion) it may be said that in the case of the psychoses the patient's emotional interest and attention is engrossed in his complexes to such an extent that he becomes submerged in them. The "gain" to him through this process is to be reckoned, as already stated, in terms of the fulfilment of an instinctive but unacknowledged attempt to escape from an intolerable emotional situation, or else to satisfy an unconscious craving.[2]

It is of no importance, as a counter argument, to say that this complex process of readjustment (the details of which I do not attempt to indicate here) would never have taken place but for the presence of a physical "disease-process" in his brain or elsewhere.

Let this be proved by all means if it be possible; or let us admit, as with Hoch, that the brain-cells may be undeveloped. We are not questioning or studying these facts, but are studying only the mechanism of the patient's attempts to find an equilibrium of a new sort.

This principle that the psychoses and neuropsychoses come into existence because they serve a purpose, has been discussed so often that I ought perhaps to assume it as granted, and pass on; but its recognition is so important for the prevention of the psychoses, that a few words of further explanation may not be out of place, the more so that the doctrine here at stake is distinctly an outcome of the psychanalytic movement.

It seems at first sight almost impossible to get away from the patient's conscious point of view, and to deplore with him and his friends, as if for a misfortune without mitigation, the signs of an oncoming mania or depression or paranoia or dementia praecox. But if, through the aid of knowledge and insight, one can succeed in placing oneself in the depths of the patient's mind, at the center of his vain struggles to make the conditions around him square with his desires, even though these be immature and narrow, it becomes possible to see that his illness may have furnished him a real way out of his perplexity, even if not the one that we, looking on, or he, if possessed of full conscious insight, might have wished to see adopted. The justice of this conception becomes clearer if one scrutinizes, to begin with, the psychologic significance of one's own fits of temporary depression, of the "blues." Whatever else the "blues" accomplish, they certainly afford us the chance to bury ourselves in an ocean of self-engrossment, self-pity or self-commendation in which we may become for the time being almost as thoroughly immersed as a dementia praecox patient in his delusions. The difference lies in the power of emergence and its special causes.

I have recently followed with great interest the gradual transition of a reactive outbreak of depressive self-pity, excited by a misfortune in business, into as severe and prolonged and typical a melancholia as one could wish to see.[3]

It occasionally happens that a patient with obsessive fears is intelligent enough (after a certain amount of treatment) and frank enough to see and say that in some respects he feels better satisfied with the prospects offered by his dissociation than by those offered by health; then, namely, when to be well means the facing of situations and renunciations that he is unwilling to contemplate. The only alternative recourse seems to be suicide. As a rule, of course, the logic of the process is concealed from his conscious view. Such persons are somewhat like children, who learn to create, in fancy, a separate realm of feeling and fancy, to which they may retreat[4] for the private enjoyment of emotions in which the other elements of their nature do not permit them openly to indulge. In this realm of fancy the child may become for the time a king, or a being to whom all sorts of excesses of imagination are permissible. If, however, he stays in this realm too long, the return into a life of relative reality[5] and social responsibility may be attended with difficulty. The justification of this comparison only becomes clear when (as sometimes in dementia praecox or paranoia) it is possible to get at the patient's delusions from their deeper and, to him, better side.

What such a child does for a brief space, when he withdraws into this delightful world of fancy, peopled, it may be, by beings from some other sphere,[6] the paraphrenic (i. e., "dissociated" or schizophrenic) patient may — in the terms of this important theory — be said permanently to do. And, *mutatis mutandis,* similar statements may be made for manic-depressive and for paranoid patients. Such persons may, namely, become in different degrees and ways, so preoccupied with the details of their "autistic" life, even when, to the untrained eye, this does not appear to be the case; they may get so immersed in their fantasies and day-dreams that they lose touch, to a greater or less extent, with the life of relative reality. During a period of many years I have had the chance to watch a young girl[7] who, although still able and even brilliant in certain intellectual lines, has been gradually sinking into such a life of fantasy, in which secret marriages, pregnancies and miscarriages play prominent parts.

We are too apt to define each other's tendencies in terms of misfortune, weakness, deficiency and lack. This procedure is misleading. There is really nothing negative in nature. If a plot of ground does not grow grass, it runs to weeds, but the weeds are as positive in their nature as the grass and often more resistive to destruction.

---

[1] See especially, as making clear the grounds for this mode of reasoning, Jung's now classical study of dementia praecox (published in English as one of the monographs of the Jour. of Nerv. and Ment. Dis.), Freud's investigation of the Schreber case of paranoia (Jahrbuch für Psychoanalytische u. Psychopathologische Forschungen, iii, 9), Abraham's study of manic-depressive insanity (Zentralblatt für Psychoanalyse, ii, 302. See also the brief but excellent study of the psychoses by Bernard Hart entitled "The Psychology of Insanity").

[2] The term "unconscious," as here used, indicates the absence of selfconscious awareness only.

[3] No psychanalytic treatment was attempted or would have been practicable. After the attack is fairly over it should be used for the prevention of a second attack.

[4] Compare Bleuler's *Das Autistische Denken,* Jahrb. für Psychoanalytische und Pathologische Forschungen, iv, 1.

[5] I say "relative reality," because even the most conventional and usual sort of life gets its form and color from the imagination of each individual. Each person's world is, in part, his personal world alone.

[6] I have a patient at present in mind, of good intelligence, but small in stature and timid in temperament, who suffers both from depression and from compensatory ideas of courage. All his life long he has gained great satisfaction from day-dreams of power and prominence. Even at the present time, when he is about 22 years old, he occasionally imagines himself to be a supernatural being, wandering through space in the skies or "talking with God," and dreams of driving a four-horse sleigh or piloting a swift boat into that unknown world from which, in reality, he shrinks.

[7] She entirely refused treatment.

Life may often be said to consist in the gradual (at times apparently sudden) abandonment of equilibriums which had sufficed well enough up to a certain point, in favor of new and more insistent equilibriums that loom up as representing, as the case may be, a more advanced (sublimated) or a more regressive (infantile) but seemingly more stable stage of evolution or of evolutionary tendency.

It is in the terms of this process that the history of the psychoses should be written.

It is important to recognize that this substitution of new equilibriums for old ones often concerns, at least in the first instance, not the whole personality, but only a part of it, and that in proportion as this happens the individual loses his unity and becomes relatively dissociated.

Also, and by the same token, the process may go on to a great extent without the active or even passive intervention of the consciousness and the constructive imagination, although these powers might, if properly trained to the work, be counted on to lend powerful assistance to the maintenance of the mental unity and to the binding of the forces of the past (which in a certain sense still lives) into one coherent whole with those of the self-foreshadowing future.

These two facts — that the mentally unbalanced person[8] is "dissociated," i. e., subject to two or more sets of strongly conflicting motives, and that this happens without the intervention of consciousness — which, however, might intervene with profit, at least in a certain proportion of the cases — are to be considered as of fundamental significance.

It is the function of psychanalysis to see that consciousness comes to its rights and is given its due share in the determination of the result.

I have, however, been led by my experience to believe that patients with oncoming psychoses, several of whom I have watched with interest throughout the gradual development of their illnesses, are very tender plants and need to be handled by psychanalysts (as by therapeutists of all sorts) with extreme care.

I also sympathize heartily with the view expressed by several experienced observers,[9] that similar care, as well as great patience and friendliness, are essential, if one wishes to do good and avoid harm in dealing with neurotic children by the trenchant weapon of psychanalysis.

But to say this is to broach the subject of prevention; and before speaking on that point I wish to discuss a little further the general claims of mental influences to be considered as both causative and curative, in theory at least.

It is obvious that the questions which are before us for consideration would never have been asked unless the belief was somewhat prevalent that the degree of liability of any given person to fall a prey to mental disorders of one or another sort was in a measure dependent on the mental influences to which he had been previously subjected. As a matter of fact, I suppose that all physicians tacitly assume this proposition to be proved, if not, indeed, self-evident — even those who would think that we ought to look for the final causes of the psychoses in brain-changes, of toxic or degenerative or hereditary origin, and who would reject the formal assertion that a purely psychogenic basis for these disorders was conceivable.

But if it makes even some difference as regards his liability to insanity, as to what mental environment a person has been subjected to, then several important inferences follow:

In the first place, if the psychoses are even partially of mental origin — i. e., "psychogenic"— who can say how far this may or might be true?

An adequate explanation, satisfactory to all disputants, of the exact etiology and nature of these serious mental disorders will, to be sure, never be furnished until the time arrives when the nature of the relationship between the body and the mind is expressible in clear and comprehensive terms.

This is largely a philosophical problem,[10] and as such cannot be discussed here. I venture nevertheless, to assert that but few students of philosophy would to-day get warm over the particular difficulty that confronts us and that forms a real stumbling block to a certain proportion of physicians. Most such students would surely encourage us to believe that a psychogenic etiology is, theoretically, just as admissible as a physical or an hereditary or a chemical etiology.[11] But when one says "psychogenic etiology," one should be understood as including all that that term implies to the man who uses it. If he believes that all mental phenomena have their physical aspect or that they are hereditary, then "psychogenic" means for him, in so far, "physical," etc. If he does not believe this, then "psychogenic" means for him purely mental.

Both practical and scientific considerations justify us in accepting as genuine any causes which *seem* to lead to these disorders, provided only that they are not reducible to simpler, more manageable terms.

One thing seems to me certain: While it is true that those who study the psychoses as diseases of the brain can count on the powerful aid of chemical and histologic tests, it is equally true that those who, on the other hand, prefer to emphasize the psychogenic aspect of this etiologic problem have the great advantage of placing themselves squarely in the position of the patient who is striving to find himself and to realize his destiny on the battle-ground of social life.

But I pass, now, from the consideration of the mechanism of the psychoses and the needs of the distinctly neurotic child to the subject of preventive education in the stricter sense, as applicable to children at large, whether at home or at school and whether sick or well; and I attempt again to answer the question, What contribution has psychanalysis to offer.

As I have already indicated, this contribution will perhaps always be mainly an indirect one. I propose nothing so insensate as that parents, or even teachers, should practice psychanalysis; but I maintain that this branch of medicine has something to offer to parents, more to teachers, and a good deal to the family physician. All these classes of persons need to have their own points of view reformed before they attempt to form the character of the child. They need a wider comprehension than that which has been current hitherto, as to what the psychologic nature of the child is, and what his purposes and his dangers are, as expressed in terms of his conflicts, his concealed and repressed thoughts, feelings and desires, and his so often misused imagination; and they need to have this knowledge on the basis of a thorough acquaintance with the psychology of human nature in general, as gained through clinical research.

---

[8] Provided that his disorder is of one of the types here in question.

[9] Compare Internationale Ztschr. f. Aerzt. Psychoanal.

[10] For the most recent discussion of this problem, from the points of view of philosophy and physical science, see the Concept of Consciousness, by Prof. Edwin Holt, Harvard University.

[11] This applies even to the psychoses of periodical recurrence and relatively long duration. It is hard to explain these periodic recurrences on any hypothesis. But it is hard also to explain the recurrences of the seventeen-year locust pests.

Needless to say I do not claim that psychanalysts have, at present, surpassing claims to recognition as physicians, educators or parents. The qualities required for serving in these capacities are numerous, and those which nature and instinct provide may, at their best, be more valuable than those gained through any kind of training whatsoever. No innate capacities are, however, so good but that they can be made still better by study and by knowledge.

In the first place, I think our current standards of conduct, and of thought as related to conduct, inadequately reflect the best conceptions of the ultimate goal of education and of life. Of course there are vast numbers of persons to whom this proposition is not applicable to any practical extent, and the proportion of these to whom it does not apply is doubtless particularly large among educators.

I presume it will hardly be disputed that the kind of person who most completely fulfils his destiny is he who looks on himself not only as a private and independent individual, but also as at once a member and a representative of the community in which he lives, then of a widening series of communities, and eventually of an ideal and all-comprehensive community. This proposition was long ago made the basis of the educational system of Froebel[12] which should be accepted as offering the best prophylactic method at our command, applicable to all children, though its influence might easily go for nothing unless reinforced by that of the child's environment and home.

But although definitions of this sort are generally accepted as indicating theoretically a suitable scheme of human opportunity and obligation, yet the observation of human conduct leads to the conclusion that the sentiments corresponding to them do not exert the thoroughgoing influence that one might look for. Obviously, these sentiments are but imperfectly accepted by some portion of the minds of most men. The very prevalence of the psychoneurotic illnesses and of the corresponding defects of character and temperament from which all men suffer in some measure, indicates that this is true. For many of these forms of illness, as well as many of the defects of character, are largely based on the self-assertion of the individual in the narrower sense, with his demand for personal "rights," and his (largely infantile, and thus selfish) longings and cravings, as against the assertion of his broader, his ideal self, recognizant rather of obligations to the community and of capabilities for usefulness than of rights.

I blame no one for this situation, and least of all do I bring an indictment against nervous invalids as a class, most of whom are handicapped and narrowed only by virtue of a necessity of development or evolution, against which they may have contended with all the force and light at their command. But the facts are so; and if it be asked what classes of persons it is that most often, even under conditions of the severest strain, escape the toils of invalidism, and of the sense of isolation that goes with it, it may fairly be said that they comprise, first, the persons of high grade such as I have just described,[13] who are able thoroughly to learn the lesson of "sublimation," perhaps because they were so "set" by nature and so favored by their environment that they could learn it easily; next, those who are so constituted—whether by inheritance or by training—that they fit adequately into the conditions by which they find themselves encompassed, and are not hampered by the visions of unattainable ideals.

It will be understood, of course, that I would classify as high-grade not only those persons whose native powers of reason and intuition, unhampered by serious defects, have been such as to enable them to grasp and define the doctrine of loyalty in its most highly developed and rational form, but all persons who are genuinely loyal to such ideals as they see. It is, in fact, this quality of genuineness that is controlling and indispensable as a factor in education and in life.

It may be urged that psychanalysis does not take the cultivation of social ideals as an end for which it should directly strive. Technically, this is true. But psychanalysts know well the evils that attend the overassertion of personal desires, cultivated too exclusively in and for themselves, and the importance of the opposite course follows by inference. The primary task of the psychanalyst is to remove handicaps to progress, but only in so far as these give rise to painful conflicts in the mind. They can, however, see and should endorse the schemes of education by which these handicaps are best avoided.

Doctrines of this sort cannot, obviously, be preached to young children, either at home or school, with any prospect of considerable benefit. If too strongly reminded, even of their social obligations and opportunities, children are likely either to react by a revolt, or to develop a hypocritical tendency, both of which results indicate the activity of that very repressive and dissociative tendency which is so objectionable.

On the other hand, teachers, parents and physicians can appreciate these principles, testing the genuineness of their beliefs, if necessary, by psychanalytic methods, and through them strong influences of the best sort can be brought to bear on the children under their charge. The best teachers do this already, but the background of intelligent cooperation should become more effective.

The steady progress toward sublimation of those individuals whose developmental tendencies are of the best sort, seems to indicate that they instinctively cultivate (in modes conforming to their age), even from the moment of their birth, the powers and pleasures which seem most personal and private, with reference to a social outcome which is soon seen to imply a loyalty to communities or social groups that exist for them only in an ideal sense;[14] while those who fail to instinctively seek this outcome are apt to exhibit, in a negative sense, a dim recognition of the binding force of these social obligations, by developing tendencies which are positively asocial or antisocial in their significance.

---

[12] Froebel: The Education of Man; see also Report on the Kindergarten by Susan E. Blow and others.

[13] This statement might be considered as misleading, but it is difficult to cover every contingency in a brief space. I do not, of course, mean to deny that nervous invalidism is to be found, perhaps to a considerable extent, among persons devoting themselves unselfishly to the public welfare. Of course, among persons of this class, as among others, innate differences of endurance are found, and specific tendencies of a neurotic sort may happen to develop. What I mean to say is that in so far as the ability to lose oneself in one's job, whatever this may be, acts as a steadying and wholesome influence, this influence is likely to be more far reaching in proportion as the job in question enlists tendencies of genuine disinterestedness, and makes it possible to put aside considerations of purely personal, as contrasted with social, interest.

[14] Compare Royce's Philosophy of Loyalty, and numerous other publications by the same writer.

Even the study of the sex life finds its most important bearing in its accentuation of the fact that man belongs to society in a sense deeper than commonly appears; that the family and, in general terms, the group should be considered as the unit, rather than the individual.

We ought to work for the maintenance of those educational systems and principles that help children first to feel and then to see that every man is most truly himself as an independent agent when he feels himself bound to merge his private interests in the interests of persons and causes outside of himself. But this tendency should go, in word and conduct, no further than it is expressive of a genuine sentiment.

Social sentiments of this better sort and the conduct based on them should not be regarded as implying standards seldom to be reached, but rather standards to which many persons might measurably attain. Children, especially, are natural idealists and respond to appeals which adults often dismiss as idle.

As illustrative of the kind of service that education can sometimes render, even to very young children, through planting the seeds of the broader sense of social obligations which is so favorable to mental solidarity and health and so hostile to the dissociation that is brought about by repression I will mention an observation, superficially trivial, but suggestively important.

A small child, who had fallen into habits of theft, became strongly captivated by the idea, which was carefully presented to him, that he could take "with his eyes," instead of with his hands, the things that he longed to appropriate, and thus gain, ideally, the satisfaction of possession, reinforced by the gratification of satisfying a dim social ideal, although obliged to renounce the pleasure of exclusive ownership,[15] with its denial of the social principle. Subsequent developments indicated that this discovery, which appealed, perhaps, primarily, to his imagination only, helped to effect a real change of temperament.

The educational system that has elaborated most thoroughly the methods of inducing or emphasizing this community sentiment as a goal of progress and has placed them on a practical footing for children between 4 and 6 years old, is undoubtedly the kindergarten system of the great thinker and educator Friedrich Froebel. Kindergartens do not by any means always come up to his ideals, but one cause of this lies in the failure of parents and their advisers to recognize the part which this system aims theoretically to play, and in their failure to give an adequate support to those who are working toward this end.

It is, however, not enough to admit the importance of a general preparatory training of this sort, even if it could be supposed that its principles were to be emphasized through the discipline of the home.

Each child has his own special needs, to be met by appreciative sympathy, direction and correction, and these needs are to be best understood when they are studied in the light of a knowledge of those to whom the tendencies to repression, dissociation and ambivalence have gone on to a more or less excessive degree.

A certain amount of repression, dissociation and ambivalence seems to be an inevitable attendant of competitive existence; but it has not been appreciated until recently at what an early stage in the child's life these tendencies may appear. It is true that, with the majority of children, neither repression nor dissociation, nor the tendency to primary or reactive emotional excess that leads to these results, is developed to any very objectionable extent. Children of the best sort, no matter how childlike and, for a time, immature their traits may be, appear to be marked by a characteristic quality that stamps every act as belonging in part to a maturer future of which it may be said to be prophetic, while, perhaps on that very account, it appears also to belong peculiarly to the present moment.

Nevertheless, the pitfalls into which so many children actually stumble (not so much because they are degenerate in the sense of having progressive brain defects, as because their power of adaptation is insufficient for the requirements of life in a given environment) should be recognized as standing open for even the most broadly adaptable child. The earliest years of all children are years of self-engrossment, the finding of themselves in the sensations that attend their reflex acts, their impulses, the recognition of their powers, desires and fears, and as reflected in the attention of their parents. And this period is beset from the outset with the danger that these new-found gratifications and excitements will be taken too exclusively in and for themselves.

The engrossment of these primary, primitive and elemental pleasures — which soon become modified by the comparisons which children institute between themselves and others, and the instructive discovery of their capacity for compensations and over-compensations — is then more or less superseded by the engrossments of their powers of fantasy, through which the unpleasant realities of the social life, for which they are still unprepared, can be shoved off for a time, in the interest of a more unified life of imagination.

Hand in hand with this tendency comes the recognition of the possibility of repressing what is too distressing, coupled with that of preserving the pleasurable aroma even of excitements that might be reckoned painful.

And here begins the double life of which every child lover should be able to see the traces and the dangers, and also, it should be said, the possibilities of added usefulness.

Children outgrow, it is true, vast numbers of habits which they are tempted to adopt in these earlier years, and it is as objectionable to see signs of permanent mischief in incidental tendencies as it is to overlook their psychologic significance. One may be trustful, but should none the less be watchful.

The principal dangers to which parents are exposed are of a twofold sort. First, they may fail to get any adequate idea of the process which is going on in the child's mind. Next, they may fail to recognize that each child, at each stage of his existence, is instinctively trying to construct a species of unified world, and is using therefor a set of symbolisms which must, perforce, be based on the sensations which he gets from his own efforts and functions, however foreign and trivial, or even revolting, the language of these symbolisms may seem to the adult.

Finally, they may let the desire to seek their own gratification (even though unconsciously) stand in the way of the best interests of the child.

This latter danger is important and familiar and although not difficult to understand is very difficult to avoid. The love of the parent for the child usually means great devotion; but this is too often given for the sake of a return in kind, and it then partakes of the character of self-love, or mirror love. This sort of devotion fetters the child instead of making him more free, whereas really disinterested love increases the child's independence by arousing in him a corresponding disinterestedness on his part, in a form suitable to his age.

---

[15] I am not attempting here a complete explanation of theft-habits, certain roots of which have been shown by psychanalysis to be very deeply rooted in infantile instincts.

The parent should be a bridge over which the child may pass to a social existence of a wider sort, carrying habits and tendencies of loyalty and service, and feeling within himself a foreshadowing sense of the larger community of which he is to become a part. But, instead, it too often happens that the father or the mother, by dint of the very exclusiveness and intensity of their own affection and the fascination of its exhibition, creates or intensifies a similar exclusiveness in the child's mind, and thus chains him to a set of private gratifications which become sensuous and exacting in proportion as they are asocial. The "father-complex" and "mother-complex" have played with good reason a large part in psychanalytic writing, as in life.[16] Repeatedly have I seen lives that should have been eminently happy, threatened with unhappiness through influences like those which I have outlined.

Another important principle which every one should know is that the fantasies and desires of children, even when their object is something which to the adult seems insignificant or unworthy, have meanings which *come near* to being good and useful meanings, and may by chance be transformed by good management into something useful and creative.

If the old saying is true, that the highwayman makes often a good turnkey, then there must have been a time when a dose of prevention would have been in place for him. And the same is the case with children. The slightly neurotic or imaginative child who is bound, at each phase of his life, to try his hand at building an imaginary world of interest, of beauty, and, above all, of power, will do this or symbolize his attempts to do so, by every means that lie at hand.

The intelligent parent will seek to see through the act or the symbol, and to appreciate the child's meanings. These meanings should be divined through real sympathy, based on close but intelligent intimacy, and should be taken at their best value.[17] For it may depend on the turn of this straw whether a desirable outcome finally emerges or whether the act or interest that might have served a good turn as a symbol and then have been replaced, becomes, through repression, the center of a hampering craving. The tendency to relive, in later years, the fantasy-life of self-indulgent childhood may arise from either of two sorts of causes; an excessive preference for the self-indulgent pleasures first exhibited at an early period when another and better choice might perhaps have been made with almost equal willingness; and a tendency to regression toward these renounced but simpler pleasures, showing itself under conditions of fatigue and strain from which every person seeks instinctively to escape. The child should be protected so far as practicable from both of these dangers, first through having ample inducements offered him for making the best choice, and, next, through being taught to do well and easily the tasks that he is to be called on to do.

In other words, his incitements to the best choice (as, especially, through the imitation of living and historic characters, and through examples afforded by literature), his adaptations and his adaptability should all be held in mind, and with special reference to the specific sorts of dangers that he must encounter.

The imagination of the young child is a weapon of immense power for evil or for good. It can be turned to the support of the reason or to the intensification of sense cravings. But on this great subject I cannot enter here.

The supplementary addition which I propose to this educational scheme is one that in a certain sense restores the ambivalent principle, as one that when rightly understood is broader than even the principle of independence and power, as commonly conceived. The best man—or child—is not alone a single individual; he is likewise a member of a community, or series of communities, eventually of an ideal community of some sort to which he feels that his loyalty is due and to which he becomes rebound. Similarly, just in proportion to the degree that a man makes himself independent of narrowing ties such as imply slavish dependence, whether based on fear or favor, or longing for approbation and attention, or jealousy or envy, and becomes in that sense independent, he becomes once more dependent on the obligations imposed by his own good qualities and powers, according to the principle hinted at by the term *"noblesse oblige."*

If such a person frees himself from the objectionable and hampering features of his childhood, he should retain, nevertheless, and all the more, the best that his childhood stands for, thus expressing, in his life, all that "religion" literally taken, indicates, namely, a rebinding accompanied by a setting-free. Nothing less than this sort of ambivalence should be, I think, the goal of education for the normal and the neurotically disposed child. This sort of rebinding which should show itself able to meet, at least fairly well, any ordinary test of genuineness is also a goal aimed at theoretically by the educational system of Froebel. It is, of course, not to be supposed that a couple of years even in the best kindergartens, much less in any given school which bears that name, is to be reckoned as a sure prevention against subsequent psychoses, any more than it is to be supposed that every person of the type to which I have above alluded as the best in kind, is to be considered as, *ipso facto,* beyond the reach of these dangers. The causative factors ordinarily involved are far too numerous for that, but one reason that I rate so high the possibilities of this system is that while it aims to use all obvious means for the development of character without needlessly calling the conscious attention of the child to this aim, it recognizes also the importance of taking some measures to prepare the child, through very simple investigations into the results of his own acts,[18] for making later, even if still only in a simple form, that kind of rational self-scrutiny which psychanalysts have learned to look on as of so much value.

One of the most obvious fruits of this rational self-scrutiny is that — contrary to the usual belief — it is destructive of that morbid, emotional self-scrutiny that goes by the name of introspection and that shows itself so often as a sign and a promoter of the neurotic disposition. I am not wedded to any one plan of education, however, and should welcome any scheme that could show evidences of its capacity to develop character, self-reliance and the recognition of community obligations.

[16] Compare papers by Abraham and by Jung in the Jahrb. f. Psychoanal. u. Psychopathol. Forsch., i, 110, 155.

[17] Compare R. L. Stevenson's Lantern Bearers.

[18] Compare The Kindergarten: A Report by Susan E. Blow and others, 1913.

Let it not be supposed, however, that this claim can, without further inquiry, be made for any and every system that makes a great point, with quasi-military vigor, on the overcoming of difficulties just for their own sake. This has its value, but it is a value that can easily be estimated too highly. After all, it is the personality and previous training of the teacher that are the elements of chief importance. But every such teacher should have been taught to accept a hint from the experience of the psychanalyst, and to use, not only general but specific means to make his personality eventually unnecessary to his pupils. The importance of following this rule was pointed out by the able Mme. de Stäel, as a consideration worthy the attention of every legislator.

GENETIC FACTORS IN ONE HUNDRED CASES OF PSYCHONEUROSIS*

DONALD GREGG, M.D.
BROOKLINE, MASS.

The object of this paper is not to present any new genetic or etiologic factors for the psychoneuroses, or to claim any one genetic factor as the origin of these nervous conditions. It is merely to present an analysis of 100 cases which have been studied to see what genetic factors have been found to occur. Theories can be met and controverted, or strengthened and established, only with the help of statistical studies. What are needed to-day are statistics of cases by hundreds and thousands. This is my excuse for presenting the following study:

The cases were gathered from the records of the out-patient department of the Boston Psychopathic Hospital. Here the clinic has been a steadily increasing one since its opening nearly two years ago, until it now numbers over 100 new cases and over 400 old cases a month. The cases are of three classes: patients discharged from the hospital that are subsequently followed up in the out-patient department; patients brought to clinic by various organizations; by court order; by charity agencies, etc., and cases of patients coming of their own initiative, alone or with friends. Over 1,500 new cases have been seen, and of these over 100, or about 7 per cent. of them, have been diagnosed as psychoneuroses and include cases of hysteria, psychasthenia, neurasthenia, etc.

METHOD

First, the statistics dealing with 100 cases as a whole will be presented, next, an analysis of various groups will be considered, and, lastly, conclusions will be drawn.

In the 100 cases studied, 57 patients were males and 43 females. The patients varied in age from 14 to 58 years. The average age was 34+. By decades the patients were distributed as follows: in the first decade, none; in the second decade, 10; in the third decade, 28; in the fourth decade, 36; in the fifth decade, 17; and in the sixth decade, 9 cases. Thus, two-thirds of the patients were from 21 to 40 years of age. Thirty-five patients were of native stock and 60 were foreign-born, or of foreign parentage. In 5 cases the stock was undetermined.

Ten years ago, Dubois wrote: "Nervousness arises from two factors: the one, essential and variable, viz.: natural psychopathic tendencies (hereditary or acquired in fetal life); the other, contingent and polymorphic—viz.: provocative agents."

An analysis of the cases for possible genetic factors showed that in fifty-six cases congenital causes seemingly existed, for the psychoneurosis subsequently developed; that is, psychopathic tendencies of an hereditary nature, or acquired in fetal life. In 44 per cent. of the cases, no such congenital causes were found. This absence of evidence of psychopathic tendency in these forty-four cases is probably explained by one or more of the following reasons: first, the large number of these patients (70 per cent.) that were of foreign stock, which means, in a majority of instances, inability to give intelligent and inclusive family histories, or histories of early life; second, the natural tendency of individuals to hide evidence of any trace of familial inferiority or deterioration; third, the impossibility in a large clinic of taking a detailed and thorough history in all cases.

The fifty-six cases considered to have probable congenital psychopathic tendencies, were grouped as follows:

1. Luetic stock: those showing evidence of congenital syphilis.
2. Insane stock: those giving a history of insanity in their families.
3. Alcoholic stock: those having alcoholic forebears.
4. Neurotic stock: those having "nervous" forebears, some of whom possibly were insane.
5. Tuberculous stock.
6. Miscellaneous stock: those having a history of cancer, asthma, etc., among their ancestors. Statistics of these groups are shown in Table 1.

TABLE 1.—FIFTY-SIX CASES OF PSYCHONEUROSIS GROUPED ACCORDING TO CHARACTER OF ANCESTRY

	No. of Cases	Sex, F.	Sex, M.	Foreign Stock, Per Cent.	Age, Yrs.	Symptom Age	Duration of Symptoms
Luetic	3	0	3	33	19.7	12.7	7.
Insane	14	7	7	35	35.7	27.2	8.5
Alcoholic	4	1	3	50	30.5	30.	.5
Neurotic	24	18	6	50	38.4	28.9	9.45
Tuberculous ...	5	3	2	60	40.8	36.2	4.6
Miscellaneous ..	6	4	2	100	39.6	32.5	7.1
Av. or total....	56	33	23	51	34.1	28.4	6.1

In this table, the most interesting point shown is the variation in age at which symptoms occurred in the different groups. It seems logical to assume that the more potent the congenital factor, the earlier symptoms may be expected to appear, or inversely, that the earlier symptoms appear, the more potent the congenital factor involved. Assuming that the symptom age bears some relation to the potency of the genetic factors involved in the production of the psychoneuroses, among the congenital factors luetic, insane, neurotic, and alcoholic defects of forebears are potent in the order named.

---

* Read before the Section on Nervous and Mental Diseases at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

In addition to the congenital or essential factors already considered, the relative importance of provocative factors such as environmental or somatic difficulties was studied. The distribution of these cases and their symptom age is shown in Table 2.

TABLE 2.—PROVOCATIVE FACTORS IN FIFTY-SIX CASES OF PSYCHONEUROSIS

Provocative Factors Stock	Environmental No. Cases	Environmental Symptom Age	Somatic No. Cases	Somatic Symptom Age
Luetic	2	14.5	1	7.
Insane	5	38.	9	25.6
Alcoholic	3	29.	1	33.
Neurotic	15	32.6	9	23.3
Tuberculous	4	40.2	1	20.
Miscellaneous	4	33.3	2	31.
Av. or totals..	33	33.	23	24.4

From these data, it seems that, given a psychopathic inheritance, an individual is likely to show symptoms of a psychoneurosis sooner when harassed by somatic than by environmental difficulties.

The cases were found to present various symptoms which were grouped under several heads: somatic, social, psychic, sexual, and religious. The frequency with which symptoms occurred in these various groups is shown by the following figures in 100 cases: somatic symptoms in 92 cases; social, in 50; psychic, in 19; sexual, in 32; religious, in 6; total, 199; average 1.9+. These figures show that the most common symptoms are of somatic nature.

TABLE 3.—ELABORATION OF SYMPTOMS

Group	No. of Cases	Duration of Symptoms
A	32	4.
A + B................	39	6.7
A + B + C.........	29	7.

In Table 3 is shown the elaboration of symptoms. Cases with one group of symptoms averaged 4 years in duration; cases with symptoms of two groups averaged 6.7 years, and cases of three or more groups averaged 7 years. In other words, the longer the psychoneurosis existed, the more complex and numerous became the symptoms.

In diagnosis, symptoms may suffice; in treatment, knowledge of the provocative agents and their removal may be essential, but in prophylaxis, the essential factors must be recognized. Within the last few years, so much stress has been laid on the provocative agents which have been brought into the limelight by psychanalysis, that the essential factors have failed to receive proper attention. No matter how early a psychoneurosis may be diagnosed; no matter how brilliantly an individual provocative agent may be pursued, captured, and dissipated by psychanalysis, psychopathic tendencies, hereditary or acquired in fetal life, will remain.

In preventive medicine, early diagnosis and successful treatment are both important, but prophylaxis is especially essential, and no successful prophylaxis can disregard or underestimate the importance of the essential factors in the production of a disease.

CONCLUSIONS

The conclusions to be drawn from this analysis of 100 cases of psychoneurosis are as follows:

1. In the majority, if not in all cases of psychoneurosis, there exists an essential factor, namely, a natural psychopathic tendency, hereditary or acquired in fetal life.

2. If the age at which symptoms occur among psychoneurotic individuals may be considered an index of the potency of the essential factor at work, luetic, insane, neurotic, and alcoholic defects among forebears are of importance in the order named in the production of psychopathic tendencies.

3. Among psychoneurotic individuals, somatic difficulties tend to induce symptoms earlier than do difficulties of enviroment.

4. The longer a psychoneurosis exists, the more numerous will the symptoms probably be.

5. Prophylaxis against the psychoneuroses can be furthered by early diagnosis, and by the elimination of the provocative agents of somatic and enviromental difficulties with the aid of medical treatment, psychanalysis, and psychotherapy, but no prophylaxis can be effective that fails to consider the essential factors in the production of the psychoneuroses.

NOTES ON PUBLIC INSTITUTIONAL WORK IN MENTAL PROPHYLAXIS

WITH PARTICULAR REFERENCE TO THE VOLUNTARY AND "TEMPORARY CARE" ADMISSIONS AND THE "NOT-INSANE" DISCHARGES AT THE PSYCHOPATHIC HOSPITAL, BOSTON, 1912-1913 *

E. E. SOUTHARD, M.D.

Pathologist, Massachusetts Board of Insanity; Director, Psychopathic Hospital, Boston; Bullard Professor of Neuropathology, Harvard Medical School

BOSTON

The technic of mental hygiene — how slender a prospectus is yet available! National and state societies, agitation for a government bureau, leaflet campaigns, after-care committees, programs of prophylaxis, all are signs of a developing propaganda. How often, as Mr. Beers of the National Committee has remarked, how often does this propaganda threaten to turn into a mere *letter-head!*

To be sure, a larger view reveals the fact that the entire movement is far more than a propaganda. A careful study of the increasing employment of the now classical plan of *voluntary admissions* to public institutions for the insane would reveal the large proportions of a deeper movement than what we now term mental hygiene. The law underlying voluntary admissions of the insane to institutions went into effect in Massachusetts, for example, in 1881. The opportunities afforded by the law were embraced by but a small number of patients, however, until the stimulation secured by a revision of the old law in 1905 (Chapter 432, Acts of 1905) permitting such voluntary patients to be supported like other patients from the public funds.

It is worth while to glance at a table illustrating the results of what was essentially a maneuver in mental hygiene. Table 1 illustrates conditions before

---

* *Contributions from the State Board of Insanity*, Massachusetts, No. 22 (1914.2). (Bibliographic Note.—The previous State Board of Insanity contribution was by E. E. Southard, entitled, "Eugenics versus Cacogenics: An Ethical Question," *Jour. Heredity*, September, 1914.)

* *Read before the Section* on Nervous and Mental Diseases at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City N. J., June, 1914.

and after the 1905 amendment to the voluntary admission law and the establishment of the Psychopathic Hospital.

TABLE 1.—VOLUNTARY ADMISSIONS TO PUBLIC INSTITUTIONS* OF MASSACHUSETTS

Year	No. of Admissions
1895-1899	405
1900-1904	520
1905	84
1906	125
1907	156
1908	195
1909	185
1910	200
1911	237
1912	282
1913	636

* Including a large private institution, McLean Hospital.

Until 1905 the voluntary admissions had run along rather evenly at 100 a year more or less, showing a slight response to the increase in general population. The majority of these patients had been private patients. After 1905 the absolute and relative numbers of voluntary admissions slowly rose up to 1913, when there was a signal and rapid advance due largely to the establishment of the Psychopathic Hospital.

TABLE 2.—ADMISSIONS WITH GROSS AND PERCENTILE FREQUENCY, 1906-1913, TO MASSACHUSETTS INSTITUTIONS

Year	Total	Voluntary	Per Cent.
1906	2,673*	125	5
1907	3,022	156	5
1908	3,195	195	6
1909	3,096	185	6
1910	3,254	200	6
1911	3,207	237	7
1912	3,350	282	8
1913	4,051	636	16

* These figures include so-called regular commitments, and both insane and sane voluntary admissions. They do not include the so-called "temporary care" group of admissions to Massachusetts institutions.

The leap from 8 to 16 per cent. voluntary admissions among the total admissions within one year is surprising. In point of fact, 440 of the 636 voluntary admissions of 1913 were admissions to the Psychopathic Hospital.

Enough to demonstrate how easy it is by setting a social mechanism in a suitable way to change the fate of various psychopaths. It is not my purpose here to investigate the value and results of the policy mentioned, although I believe it to be obvious that good must accrue. I think it worth while to print the text of the voluntary admission law of Massachusetts, hoping that some readers who live outside the boundaries of the sixteen states having such laws will be minded to push for the enactment of similar laws in states whose civilization has not reached that point. This reads as follows:

VOLUNTARY PATIENTS. R. L. 87

Section 45. The superintendent or manager of any institution, public or private, to which an insane person may be committed, may receive and detain therein as a boarder and patient any person who is desirous of submitting himself to treatment, and who makes written application therefor and whose mental condition is such as to render him competent to make the application. Such person shall not be detained for more than three days after having given notice in writing of his intention or desire to leave the institution. The charges for the support of such person in a state institution shall be governed by the provisions of law applicable to the support of an insane person in such institution, provided the approval of the state board of insanity shall be obtained in writing.[1]

Nevertheless, although it is certainly but semicivilized for a state to remain without the mechanism for voluntary admission of insane persons to public institutions, I should hardly go so far as to advocate as yet for all communities laws like the *temporary care* laws of Massachusetts. Perhaps they require further testing before they can be regarded as perfect. I give the more important of these laws, that dealing with seven days' care without commitment, hoping that its humanity will appeal to those whose communities are prepared to favor the patient's cause *as patient* at an apparent slight risk to his rights as an individual:

CHAPTER 395, ACTS OF 1911

AN ACT RELATIVE TO THE RECEPTION AND TEMPORARY CARE IN CERTAIN INSTITUTIONS OF PERSONS SUFFERING FROM MENTAL DERANGEMENT

The superintendent or manager of any hospital for the insane, public or private, may, when requested by a physician, by a member of the board of health or a police officer of a city or town, by an agent of the institution's registration department of the city of Boston, or by a member of the district police, receive and care for in such hospital as a patient, for a period not exceeding seven days, any person who needs immediate care and treatment because of mental derangement other than delirium tremens or drunkenness. Such request for admission of a patient shall be put in writing and filed at the hospital at the time of his reception, or within twenty-four hours thereafter, together with a statement in a form prescribed or approved by the state board of insanity, giving such information as said board may deem appropriate. Such patient who is deemed by the superintendent or manager not suitable for such care shall, on the request of the superintendent or manager, be removed forthwith from the hospital by the person reqesting his reception, and, if he is not so removed, such person shall be liable for all reasonable expenses incurred under the provisions of this act on account of the patient which may be recovered by the hospital in an action of contract. The superintendent or manager shall cause every such patient either to be examined by two physicians, qualified as provided in section thirty-two of chapter five hundred and four of the acts of the year nineteen hundred and nine, who shall cause application to be made for his admission or commitment to such hospital or, provided he does not sign a request to remain under the provisions of section forty-five of said chapter five hundred and four, to be removed therefrom before the expiration of said period of seven days. Reasonable expenses incurred for the examination of the patient and his transportation to the hospital shall be allowed, certified and paid as provided by section forty-nine of said chapter five hundred and four, as amended by chapter four hundred and twenty of the acts of the year nineteen hundred and ten, for the allowance, certification and payment of the expenses of examination and commitment.

I do not here discuss the operation of this seven days' care law, but merely wish to call attention to the stimulation afforded by the establishment of the Psychopathic Hospital to the drawing from the community of many persons suspected of insanity under conditions relieving them of stigma and expense in case they are proved not to be insane.

By the courtesy of Dr. Menas S. Gregory of Bellevue Hospital, I also include the text of a law passed by New York State in 1912, dealing with an ambulance service for the insane. This law goes in some respects further than the Massachusetts law and is worth considering by all interested in improving the care of psychopathic patients.

---

[1] It is the provision for *public support* of voluntary cases, herein provided, that turns the *voluntary* admission case into an important means of mental hygiene.

AMBULANCE SERVICE FOR THE INSANE

One of the most important and far-reaching steps in divorcing the medieval legal interference in the care and handling of the mentally diseased has been the recent change in the insanity law expediting and facilitating the admission of the mentally sick to the psychopathic wards. Section two of chapter thirty-two of the Laws of 1909 was amended March 5, 1912, to provide as follows:

> It shall also be the duty of such trustees of Bellevue and Allied Hospitals . . . to see that proceedings are taken for the determination of the mental condition of any such person in the boroughs or county mentioned, who comes under their observation or is reported to them as apparently insane, and, when necessary, to see that proceedings are instituted for the commitment of such person to an institution for the care of the insane; provided that such report is made by any person with whom such alleged insane person may reside, or at whose house he may be, or by the father, mother, husband, wife, brother, sister, or child of any such person, or next of kin available, or by any duly licensed physician, or by any peace officer, or by a representative of an incorporated society doing charitable or philanthropic work. When the trustees of Bellevue and Allied Hospitals are thus informed of an apparently insane person, residing in the boroughs of Manhattan or the Bronx, it shall be the duty of these authorities . . . to send a nurse or a medical examiner in lunacy, attached to the psychopathic wards . . . or both, to the place where the alleged insane person resides or is to be found. If, in the judgment of the chief resident alienist of the . . . psychopathic wards, or of the medical examiner thus sent, the person is in immediate need of care and treatment or observation for the purpose of ascertaining his mental condition, he shall be removed to such psychopathic ward for a period not to exceed ten days, and the person or persons most nearly related to him, so far as the same can be readily ascertained by such trustees, . . . shall be notified of such removal.

TABLE 3.—ADMISSIONS UNDER THE SEVEN DAYS' TEMPORARY CARE LAW OF MASSACHUSETTS

Admissions in 1911 (after June 4)	92
Admissions in 1912 (Psychopathic Hospital opened June 24)	416
Admissions in 1913	897

Of these 897, 590 were sent to the Psychopathic Hospital, the others to other institutions of the state.

These two examples — the increase in voluntary admissions and the increase in temporary care admissions — are enough to show what an engine of prophylaxis a psychopathic hospital, backed by proper laws, may become. Accordingly the Psychopathic Hospital deserves reckoning as one of the major departments of the prophylactic division of mental hygiene.

Every person admitted under the voluntary law is entitled to consider himself in one sense a free man, quasi-sane, or at least not antisocial, unless on his application to leave, steps are taken to commit him. Again, every patient temporarily cared for is entitled to consider himself as not yet *proved* insane, although he may be aware that alienists are examining him. Even if he is eventually to remain in an institution, he may well become such inmate voluntarily and, even if committed against his will, he has at all events the satisfaction of knowing that he was given a good chance of avoiding commitment by a period of hospital observation.

The proof of the pudding is the real object of my present communication. I have chosen to investigate the large "not insane" group of the Psychopathic Hospital's discharges to ascertain, if possible, just what benefit to the patient and to society has accrued from passing these persons through the psychiatric filter. How much a factor in *successful* prophylaxis are these "not insane" discharges?

For the moment, I do not deal at all with so-called "recovered" or "improved" cases that have been judicially recognized as insane. Of these recoveries there were in a period of about twenty-one months 195, and of "improved" cases, 177, or a total of 372 among 2,500 discharged from a hospital largely diagnostic in its functions, and with an average duration of hospital treatment not over three to four weeks.

I wish rather to consider among these first 2,500 discharges a group of 570 other cases regarded as not insane, and in fact as never yet insane. This group forms between a fifth and a quarter of our discharges (23 per cent.), calculating on a basis of our first 2,500 discharges. Of these 570 "not insane" discharges, 405 can be briefly disposed of from the diagnostic point of view as in Table 4.

TABLE 4.—"NOT INSANE" DISCHARGES WITH ASSIGNED DIAGNOSES

Feeble-minded *et al*	179
Psychoneuroses *et al*	100
Alcoholism	44
Epilepsy	39
Somatic and non-mental diagnoses	27
Syphilis	17
Brain disease of various types	10
Chorea	6
Paralysis agitans	2
Acromegaly	1
Other diagnoses	6
	431
Diagnoses in more than one case	26
	405

The significance of most of these figures is obvious. I will dismiss the feeble-minded group (179 cases), remarking that at least fifty-one of these may properly be regarded as belonging in the group of so-called "defective delinquents," using this term to include many who have never been considered by courts and who might better be termed potential delinquents. There promises to be a mine of criminal-anthropologic data among these cases, the more so in that alienists have not ever intensively studied large groups of these cases by the best methods in hospital wards. Reports should eventually become available of a large group of cases studied not merely with the Binet-Simon tests, but also from the point of view of the new "point scale" of estimate now about to be published by Robert M. Yerkes, psychologist to the Psychopathic Hospital. Meantime the value to the community of these examinations at a center having the stamp of authority is certainly large. Since a majority of these cases fall in the higher grades (by the Binet-Simon and other standards) it is possible that the amount of community prophylaxis thus afforded will eventually reach a high level, since the most difficult community problems in the field of feeble-mindedness are recognized on all hands to lie with the higher grades of feeble-mindedness.

I cannot forbear mentioning here, without developing the point, that a considerable advantage is accruing to the local social-service public from the making clear to them that the terms "feeble-minded" and "insane" (or, better, "psychopathic") are not terms equivalent to "should be sent to an institution!" With the organization of social service in various centers there has developed a certain tendency to bureaucracy, and to the conception that medical groups are institutional groups. Of course this runs counter to the underlying principles of social service, which, I take it, starts from a foundation of differentiated individual service. The basis of differentiation among psychopaths needing social service is very likely to be medical and not economic. Accordingly I feel that such an institution as the Psychopathic Hospital is likely to be salutary in any social service situation where bureaucracy tends to lift its head.

I will, secondly, dismiss the group of alcoholics (forty-four cases), remarking that they represent (*a*) certain cases of acute nature (considered *not* to be examples of delirium tremens or of the so-called pathologic intoxication or of any other form of mental disease, but) having a variety of mental symptoms demanding temporary care, and (*b*) certain cases of a chronic nature with acute exacerbations threatening to become antisocial. The advantage to the community of this service is obvious. The patients in question would formerly have gone to jail doubtless in most cases. The number of such cases does not represent the volume of the social problem they present. I will dismiss the topic, referring the interested reader to the conference on medical and social aspects of mental disease due to alcohol,[1] held at the Psychopathic Hospital before the legislative commission on drunkenness, Nov. 24, 1913. Article VI, from that conference report, by Dr. A. Warren Stearns and Miss Mary C. Jarrett, deals with the after-cure and moral suasion work of the Psychopathic Hospital. Although alcoholism forms only about one-ninth of the Psychopathic Hospital's problem, yet much attention has been given to the topic, and thirteen communications have been made to medical journals about it, twelve of which appear or are referred to in the report of the conference above mentioned and the thirteenth (on the treatment of deliria) has been published by Donald Gregg.[2]

Epilepsy (39 cases), syphilis (17 cases), various types of brain disease (10 cases), chorea (6 cases) and 9 miscellaneous cases need not be especially considered here, despite the attractive vistas which several of these fields bring up to the alienist, who is apt to feel that the mental complications *of the early phases* of various nervous and allied disorders have not been given adequate attention by neurologists untrained (at least in any modern sense) in psychiatric method.

Perhaps a group of 27 cases, tabulated as having "somatic and non-mental diagnoses," deserves more particular attention than I can at present give. I find 8 among these belonging to the in all ways difficult group of the morphinists, 5 to the group of dysthyroidism, 4 senile cases thought not to be psychopathic, 2 cases with some mental symptoms in advanced tuberculosis, 2 cases with mental symptoms in typhoid fever, etc.

I have reserved a group of 100 cases of psychoneurosis for consideration as a problem of great importance in any campaign of mental prophylaxis. The group was made up as follows: hysteria, 45; neurasthenia, 20; psychoneurosis not further specified, 20; psychasthenia, 10, and psychopathic personality, 5. I suppose the question uppermost in the alienist's mind as to this group is how far these cases are open to individualistic, and how far to specific or more general, lines of treatment. I take it that for the present it is well to give the patient the benefit of the doubt and individualize treatment as far as possible, although I hardly feel that the point has been proved. As between the therapeutic method that goes under the name "psychanalysis," the method called "rest treatment," the "work treatment," and what might be called calisthenic treatment, it is a question whether science can yet say that one treatment is always better than others, or that one treatment is good for Patient A and another for Patient B, or that no one of the methods is of avail in certain cases.

I know of no accurate estimates of the volume of such disease in the community. Here it seems as if about one-quarter of the not insane (but in some way psychopathic) cases resorting rather freely to the Psychopathic Hospital belong to the psychoneurotic group. It is natural to suppose that the severer examples of the group are the particular cases which reach the hospital. If the total 2,500 cases may be regarded as somewhat fairly representating the serious forms of mental disorder (all types) in the community, then one in twenty-five of these belong to the theoretically so interesting and practically so important group of the psychoneuroses.

Before the community plunges into the program of building public sanatoriums for this class, more figures should be available. Perhaps if we should combine certain convalescents from insanity with these psychoneurotics, we could justify on numerical grounds the establishment of such sanatoriums, having after-care and preventive functions. It seems doubtful whether the public funds will soon become available for this purpose, however worthy; but it would seem that private appeal could be very legitimately made for such institutions. It is a curious thing that some of the richest privately endowed institutions for the insane in this country have not seen their way to the establishment of such sanatoriums and preventoriums for the poor. Instead, we often find these endowed institutions successfully pushing claims for large private benefactions, but operating their wards on a system of high-priced treatments. Free beds for cases of this group are often hard to discover, at all events hard to find *empty!*

All that a psychopathic hospital, situated in the midst of a medical center (for the sound reason that otherwise not scientific men enough can be gathered for proper diagnostic work), can do with a problem like that of the psychoneurotics is to:

1. Effect certain cures of the magical order (though how permanent these are is a question, and how good for the patient's utlimate fate);
2. Apply "rest," "work," calisthenic and similar treatments (which unhappily can often not be carried on long enough for economic reasons);
3. Enlist private interest in individual cases requiring longer attention (methods of social service in discovering special private sources of aid);
4. Persuade suitable patients to submit to voluntary admission to state insane hospitals, there to stay for a time under rural conditions, enlisting the interest of resident physicians and overlooking the fact of association with the frankly insane (the cottage type of institution planning greatly helps here, because of the possible differentiation of cottages for psychoneurotics);
5. Endeavor to discover underlying causes.

If such a sanatorium for psychoneurotics were to be founded, it would be well not to divide it equally between the sexes. The psychoneurotic hospital should have more beds for women. Table 5 gives the incidence of 100 psychoneuroses according to sex in which twenty-nine patients were male and seventy-one female.

Tables 6 and 7 show that half of the psychoneurosis patients came to the hospital between the fifteenth and thirtieth years, and a little over one-half of the female cases (37:71) were between those ages.

Under 16	1	6	7
Over 30	15	28	43

Certain points about the syphilis index and the sex distribution at different ages have been placed in Paragraphs 11 and 12 of the summary.

SUMMARY

1. In the prophylactic division of mental hygiene the matter of voluntary admissions to hospitals for the insane holds a primary place; their number is increased by the plan of supporting such at the public charge just as committed cases are supported, and is still further increased, and even doubled, by the provision of a modern psychopathic hospital (increase from 8 to 16 per cent. of the total of voluntary and committed cases, experience at Boston Psychopathic Hospital).

2. A second prophylactic measure is the provision of proper temporary care for persons suspected of mental disease, as according to a unique Massachusetts temporary care law (first operative in 1911; see text). This provision has been eagerly employed in Massachusetts, more than doubling the number each year since enactment. The Psychopathic Hospital is receiving about two-thirds of all those thus received in Massachusetts, 1913.

3. Many important prophylactic questions relate to those thought to be insane but not proved to be. In this psychiatric borderland also lie many questions between insanity and feeble-mindedness. A large "not insane" group, namely, 570 cases among the first 2,500 discharges from the Psychopathic Hospital, has been reviewed to discern the general features of this psychiatric borderland of diagnosis.

4. Consideration is omitted of 372 additional cases regarded as recovered or improved after attacks of mental disease, although in one sense these cases are open to prophylactic measures, since the occasional review of these cases by a follow-up system must tend to help society, and may help the individual.

5. Of the 570 not insane cases, 179 were cases of feeble-mindedness of various grades, largely of the higher grades and including a large number of the so-called defective delinquents (more than fifty). In this connection it often becomes necessary to fight a bureaucratic tendency among social workers who tend to proceed on the erroneous assumption that an insane or a feeble-minded person belongs by definition in some public or semipublic institution.

6. The numerically next largest group is that of psychoneurotics (100), who are largely female (71), especially the hysterics (39 female in 45). Consideration is given to the idea of a *public sanatorium* or preventorium for such persons with far larger provisions for females than for males. It is thought that these cases, *forming at least a twenty-fifth* (probably more) of all mental cases in the community and at least a fourth (perhaps somewhat more) of all not *insane mental cases, might perhaps warrant*, if combined with the convalescents, the establishment of a public sanatorium to be run on economical lines in the country.

7. It is largely the great expense (from $20 to $25 per week) of caring for these cases in a centrally placed psychopathic hospital or psychiatric clinic which determines the idea of a rural public sanatorium; for psychotherapy (in whatever form may be determined to be valuable), rest treatment, work treatment and calisthenics, to say nothing of dietary and other general measures, *can be as well, though more expensively*, carried out in the urban psychopathic hospital.

8. Of the 570 not insane discharges, 165 were not classified as showing any particular form of mental or other defect, although it must be emphasized that each of these came for psychodiagnostic reasons and was admitted under a special form of law. One even was a case regularly committed under judicial procedure but later determined to be not insane, and nine others came under judicial authority by virtue of certain other laws not commonly used.

9. Of these 165 not insane discharges, ninety had been admitted under the temporary care law, unique in Massachusetts, referred to in Paragraph 2 (except in fifteen instances in which a somewhat similar law, operating for the city of Boston alone, was employed). With respect to these persons it must be emphasized that their problems would not have been so easily solved under any other procedure. Examples of such problems are question of paraphrenia systematica, question of hysteria, question of defective delinquent, question of epilepsy, etc.

10. Of the 165 not insane discharges, sixty-five either resorted voluntarily to the hospital or were pursuaded to become voluntary patients. It is evident that, in an increasing number of instances, persons realize or can be made to realize the possible psychopathic nature of their difficulties and come almost eagerly even to a public institution.

11. About 13 per cent. (18 in 136) of these persons who were discharged as without active symptoms of mental or other disease yielded positive Wassermann reactions in their serums. The interpretation of this fact is doubtful. The percentage in the males was 10 (7 in 65), in females 16 (11 in 71).

12. Two-thirds of the patients aged 6 to 15 were boys (21 boys, 10 girls), but of those aged 16 to 25, there were more than four times as many women as

men (10 men, 45 women). From 26 to 40, the sexes are about evenly distributed (17 men, 19 women). Then males preponderate (28 men, 14 women). Thus, women may be thought to get into suspicious psychopathic circumstances which later resolve, much more often in the period of adolescence, males somewhat more often in late boyhood and in postadolescent years. Therein lodges a problem in prognosis which if settled would greatly aid the alienist, particularly, in making certain social decisions.

13. It is clear that the influences which are bringing the not insane to the Psychopathic Hospital in Boston are bringing them there at comparatively early ages, and often (especially the females) in adolescence. The community's interest in the question of feeble-mindedness and the social worker's often justifiable desire to institutionalize her wards are powerful factors in this resort for diagnosis to a state institution. The physicians in the community are almost to a man, I believe, pleased with the increasing facility with which, under the laws mentioned above, some of their most difficult problems are solved. Time was when almost the only recourse in determining absolutely whether a patient was insane was to adjudge him insane and release him afterward if a mistake had been made. To overcome this difficulty, various devices have been adopted in the more highly civilized of our states. The Massachusetts arrangements are of particular interest to those who may not have been able as yet to civilize their own states in these directions.

74 Fenwood Road.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. PUTNAM, GREGG AND SOUTHARD

Dr. D. J. McCarthy, Philadelphia: I believe that the social service idea, which has been promulgated by Dr. Cabot, began as a medical idea and then switched over to special social service along modern lines. The difficulty lies in the idea of placing a non-medical person in a position of responsibility to determine what shall and shall not be done with certain individuals. Social service is a medical problem necessarily, and we must look to the future social service work for such careful investigation of families and houses as was done in the crusade against tuberculosis in Berlin. Medicosocial service by large corporations is becoming practical everywhere, as in large department stores where thousands of young women are employed. If all such could be prevailed on to adopt social service, and if we had such an institution as Dr. Southard suggests, which is not purely charity, where the individual could be treated for one dollar a day, where the young woman losing 15 or 16 pounds a month progressively and showing nervous symptoms, irritability, etc., could be taken before she breaks down and where there would be no stigma of insanity, but simply the recognition of a condition of overwork, such an institution would be of immense help in the prevention of psychoneuroses. If these patients are not seen early before the break, when the symptoms are developing and the individual is losing efficiency, the most important factor in the prevention of psychoneurosis will be lost. Frequently patients come to us after the break has occurred, impelled by social reasons, but even in a mild case of mental disease the patient is not well in six weeks, and danger lies in putting him back to work in three weeks. It is a matter of from six months to two years before the nervous system is sufficiently stabilized to put that person back where he can do good and efficient work.

Dr. M. A. Hallowell, Vineland, N. J.: I have been handicapped because certain fields that belong to physicians have been relegated by physicians, I am sure not wilfully, but by default, to others. Certain phases and factors, I feel, are extremely important. One is the field work. It is being done throughout the United States by non-trained workers. As neurologists do you not think that a psychopathic institution where medical men shall be specialized for this particular work and equipped to do the work properly, is much needed? At present the workers are absolutely untrained; they are people who are social workers with an absolute lack of knowledge of medical subjects; they do not know how to bring out the leading factors in the etiology of disease. It is most important that medical people should get together and make it possible to put trained medical workers in this field.

Another extremely important point is that, in the United States, juvenile courts, or the child-welfare bureaus in connection with juvenile courts, are making the tests as to the relative normality of the children. Is it physicians and psychiatrists who are committing these children to the institutions for the feeble-minded, or prescribing treatment when the children are placed on probation? It is not physicians, it is not people who are qualified to do this work. Physicians in general are accepting reports from these bureaus not presided over by physicians; they are taking these reports as definite and conclusive, whereas, patients are committed to my institution, as to others, who are absolutely normal, but whose accustomed environment has been taken away from them; they have hardly become adjusted to the new environment, and their reaction is not pathologic, but the pendulum is swinging too far. The lay people who make these tests, who are responsible for this work, and who are doing it to the best of their ability because physicians are not taking it up, are in many instances mistaking those children with antisocial instincts for feeble-minded. I hope that physicians in general, the American Medical Association, and the neurologists of the country, will try to see that the field workers who make these family histories and beautiful charts shall be people who are qualified; that when a type of the feeble-minded or epileptic or alcoholic, or whatever type may be charted, is presented, we may be perfectly sure that it is a true type. We are not perfectly sure, with the charts in existence at the present time, as to whether or not most of the records are true. I know the handicap that physicians and neurologists suffer because there are no trained physicians to do this work. It is a wonderful opportunity for young physicians, and for psychopathic institutions to train young physicians to take up this work.

Dr. Walter B. Swift, Boston: I am glad to see the weight of Dr. Putnam's paper placed on synthesis and sublimation. Up to the present the psychanalytic movement has been mostly description, analysis, interpretation, with very little said about what to do, how to synthesize, when to sublimate, and who should do all this. In the first part of his paper Dr. Putnam has now swung the emphasis over to this utilitarian side. And I trust that from this date the balance will stay thus tilted. A word, then, is apropos as to the source of synthetic methods. Dramatic art contains more synthetic methods, that is, in the norm, than any other field of study I know. I have a personal interest here. There is more good psychology remaining still scientifically uninvestigated in the field of dramatic art than anywhere else. Students of synthesis can learn much from that field. A good idea of the intricacies of syntheses there contained can be grasped by picturing in the imagination for a moment all the varieties of synthetic processes that are necessary for the personification of another's personality.

I differ with Dr. Putnam when he says that the symptoms of the psychosis and the psychoneuroses are the patient's efforts to recover. Granted that every organism has an innate tendency to right itself when diseased, these symptoms appear to be more than that—a sort of let-up of certain previously controlling inhibitory centers, more of an uncontrolled expression than a controlled expression aiming at recovery. It sometimes almost seems true that some of these disease forms may have an etiologic basis in the brain anatomy—in the inherited variation of size of cell nuclei—so that a small area getting easily tired or depleted, lets up its inhibitory control under stress of somatic disease or environmental pressure and away the combination flies. Why could there not be, then, between the psychanalytic interpretation and the neuro-

EFFICIENCY OF SODIUM CHLORID IN THE THERAPEUTICS OF BRIGHT'S DISEASE

A FURTHER CLINICAL STUDY*

H. LOWENBURG, A.M., M.D.
Assistant Professor of Infantile Dietetics, Medico-Chirurgical College; Pediatrist to the Mount Sinai Hospital; Pediatrist to the Jewish Hospital; Assistant Pediatrist to the Philadelphia General Hospital
PHILADELPHIA

In September, 1912, in the Section on Medicine of the Medical Society of the State of Pennsylvania, which met at Scranton, I reported my experience with the use of sodium chlorid in the prevention and in the treatment of nephritis and edema. My conclusions as to the efficiency of this agent, employed as a normal solution by hypodermoclysis and by the drop method by rectum, were based on purely empyrical and clinical data. The latter included three cases of nephritis, two of typhoid fever, three of scarlet fever and one of infantile dysentery. I at that time observed that "the results in each instance were so strikingly uniform and identical that one cannot escape the conviction that they appear to be more than coincidental and to depend on definite biochemical phenomena which were determined by the physiologic activity of the therapeutic agent employed."[1] Then as now my results appear to me clinically to confirm the experimental observations of Martin H. Fischer[2] with reference to the nontoxicity of sodium chlorid in cases of nephritis with especial reference to its effect on water retention (edema) and on the kidney substance itself (albuminuria, cloudy swelling and cast formation). All cases in which this agent was employed, save one very severe instance which will again be mentioned, were relieved. It may not be out of place to remark that my original observations were made before I became acquainted with Fischer's work so that my results appear to me to be more valuable as confirmatory data.

I wish again to speak simply as a clinician, being without animal, experimental or other memoranda, and desire only to add to the number of cases previously submitted. My hope is that, perhaps in discussion, more convincing light may be thrown on the not yet settled questions as to whether sodium chlorid induces water retention, as to its influence on the actual kidney condition in nephritis, on the symptoms of the disease in general and as to the real nature of nephritis and edema.

In this connection it may be interesting to review briefly some of the theories as to the production of edema. The most noteworthy clinical contribution has been made perhaps by Widal and Javal.[3] Their work is well known and has been accepted by many clinicians as essential to the correct therapeusis of nephritis. My own experience, however, has not been in accord with their teaching, that an edema may, in a nephritic, be made to come and go by the administration or by the withdrawal of sodium chlorid. On the contrary, as a later reference to my cases will demonstrate, not only is this agent non-toxic to the nephritic or to the infant suffering from the so-called idiopathic edema of gastro-intestinal origin, but it is helpful and even curative. It has also been noted, personally and certainly by others as well, that the administration by hypodermoclysis of warm normal salt solution to marantic infants with subnormal temperatures or to wasted infants who have been dehydrated and demineralized as the result of a severe summer diarrhea (intoxication) has been followed by prompt absorption and elimination of the fluid and that edema has not ensued. Jacobi[4] has for years advocated the administration of additional sodium chlorid in the milk formula. I have uniformly followed his teaching and in no instance have I seen edema develop in either the sick or the well-feeding patient that could consistently be ascribed to this cause.

The studies of Cowie, on the other hand, would lead one to conclude that sodium chlorid retention is responsible for edema in wasted infants.[5] He believes that the action of the hydrochloric acid in the stomach on large doses of sodium bicarbonate increases the amount of sodium chlorid in the system and thereby induces water retention. I too have seen edema develop in cases of pyloric obstruction in which frequent washing of the stomach with a strong solution of sodium bicarbonate had been practiced. This need not necessarily be explained on the ground of salt retention as it occurs in some infants wasted from this disease and from others who have received neither sodium bicarbonate nor sodium chlorid.

Opposed to the activity of sodium chlorid as the sole etiologic factor in edema, although frequently quoted as supporting this view, are the conclusions of Stoltzner, Wagner, and Cohnheim. Each of these observers regarded the presence of some other substance as necessary. Cohnheim[6] could produce edema in wasted infants by the injection of salt only in conjunction with some local irritant as Spanish fly or the direct rays of the sun. Wagner[7] regarded the presence of a toxin of intestinal origin as a necessity. Stoltzner[8] believed that the edema resulted from the irritation of the blood-vessel walls by a toxin which likewise irritated the kidneys and resulted, as well, in albuminuria. The conclusions of these observers, especially those of Cohnheim and of Stoltzner, appear to forecast, as it were, and at the same time to lend support to the contentions of Fischer, that the edema and the albuminuria depend on general tissue acidosis, not excepting the kidneys. The effect of the acid in the latter instance is to cause the solution of the gelatinous colloidal substance of which the kidney is composed. This results in albuminuria.[2] His simple experiments as to the effect of non-acidulated and of acidulated solutions on the solution of fibrin and of gelatin and as to the restraining effect of the mere presence of neutral salts, notably sodium chlorid, on the dissolving action of the acid, appear to provide ample substantiation for his view that nephritis and its concomitant features, albuminuria, edema, etc., depend on the effect of acid on gelatinous colloidal tissue, and that this effect may be destroyed by sodium chlorid and alkalies. Fischer produced nephritis in rabbits by the injection of acid. He prevented the occurrence of nephritis by the simultaneous injection of acid and sodium chlorid. He cured nephritis in rabbits by the injection of sodium chlorid and sodium carbonate after producing it with acid. There is also sufficient evidence to support the view that a salt-free diet may actually lead to albuminuria and nephritis. Quoting from the works of G. Bunge, J. Forster and N. Lunin, Fischer explains this phenomenon as due to the low salt content of the body which occurs as the direct result of food without salt and the ingestion of large amounts of water poor in salts. The water washes out the natural salts already present. This salt starvation leads to systemic and renal acidosis and this to nephritis as represented by albuminuria, cloudy swelling, casts, and edema.[9] Sodium chlorid is a conspicuous example of a neutral salt of a monovalent ion. Up to a certain point of concentration this will inhibit the action of the acid and together with an alkali will entirely overcome the effects of the acidosis. To the bivalent and to the trivalent ion is ascribed even greater power of inhibition.[10]

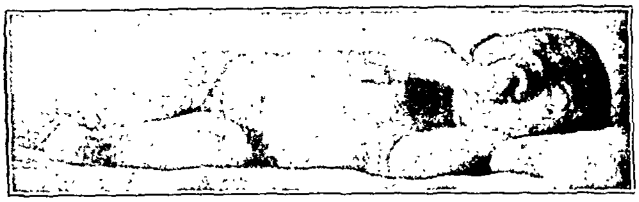

Fig. 1.—Idiopathic edema (Case 1). Pitting of leg and edema of face and skin of dependent portion of abdomen are shown.

With reference to the neutral salts, as represented by Ringer's solution (which contains chlorid of sodium, potassium and calcium) as being responsible for an increase in the flow of urine in experimental nephritis which Fischer produced in three ways (interference with respiration, intravenous injection of acids and clamping of the renal vessels), his statements are so startling that one is almost at first unable to realize their force in view of the universal acceptance of the teachings of Widal and Javal.[11] In whatever manner he produced nephritis he was able to overcome its effects by the use of this solution or by any neutral salt. Also by the use of sodium chlorid solution he enormously increased the urinary output and not only prevented edema but cured it as well.[12] This I have been able to confirm clinically with the use of sodium chlorid solution by hypodermoclysis.

The restraining effects of Ringer's solution and a sixth-normal solution of sodium chlorid on the occurrence of edema is seen in frogs in which nephritis has been produced by the injection of uranium nitrate.[13]

One can have no quarrel with those who differ with Fischer's views and attack his experimental data and conclusions.[14] One cannot, however, peruse his work without recognizing the fact that he has placed himself squarely on record as opposed to the application of the salt-free diet in the treatment of nephritis and to the idea that this and other neutral salts are toxic to the nephritic. He advocates their use as curative and preventive agents in conjunction with alkalies. My experience, as before stated, gained independently of a knowledge of his views, causes me to believe that his work has for some reason not attracted the attention which it merits.

My cases include one case of cardiorenal disease complicating exophthalmic goiter in an adult which I was permitted to observe through the courtesy of Dr. Helen Kirschbaum, three cases of non-renal and non-cardiac edema occurring in emaciated infants, the so-called idiopathic edema or edema of gastro-intestinal origin of infancy and four cases of actual nephritis.

In the cases of nephritis now reported and in those detailed in 1912 no attempt was made to classify them as tubular, vascular or azotemic according to the functional tests described by Schlayer. According to this author in the first variety salt and iodids are slowly eliminated while milk-sugar speedily passes out. In the second type the reverse occurs. In the last a 10-grain dose of urea is but slowly thrown off. In all instances the diagnosis simply of nephritis was made by the clinical symptoms and the urinary findings. Most of the cases followed some acute infection as tonsillitis, scarlet fever and adenitis. Clinically and pathologically also it is probably true that simple vascular (glomerular) and tubular nephritis rarely occur alone but that in every case a combination of pathologic changes exists. These observations are made because all patients practically received the same treatment and in all instances the effects, especially on the edema, were identical. All received large amounts of water orally and hypodermically and in no instance were symptoms intensified from this agent alone which, according to the teachings of von Noorden, provides additional irritation to the vascular system of the kidneys. All patients received as well enormous doses of sodium chlorid and in all instances save one (Case 8) the daily amount of urine was materially increased.

Case 1.—Boy, aged 6 months, weight 10 pounds, admitted to my service at the Mount Sinai Hospital, May, 1913. Bottle-fed. Previous history has no bearing on present condition. Infant is edematous over its entire body (*Fig. 1*). Temperature subnormal. No cardiac, renal or hepatic disease discoverable. Treatment: Subcutaneous injection of the following solution under the skin below the nipples on alternate days: sodium carbonate, crystallized, 10 gm., sodium chlorid 14 gm., water 1,000 c.c. About 250 to 300 c.c. daily. Edema entirely absent on the *eighth day* of treatment. Infant now showed all the features of marasmus. Weight 8 pounds 3 ounces. Unfortunately no photograph was taken. There appeared under the right nipple an extensive slough which would not heal and which finally exposed the whole pectoral muscle. The infant died from inanition and exhaustion.

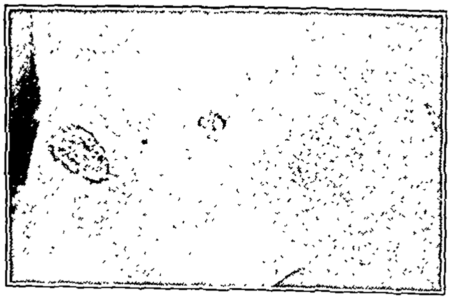

Fig. 2.—Sloughing areas from subcutaneous injection of alkali and salt solution (Case 5).

Case 2.—Boy, aged 9 months, seen in the service of Dr. W. C. Hollopeter and myself at the Philadelphia General Hospital. Bottle-fed. Emaciated and edematous about the legs, feet, thighs, lower abdomen and face with slight involvement of the hands. No discoverable lesion to account for edema. Temperature subnormal. Received normal saline solution by hypodermoclysis on alternate days under skin of abdomen. This was continued about ten days. Edema was entirely relieved and the infant made an uneventful though protracted recovery.

[15] Fischer, Martin H.: Nephritis, p. 190.

Case 3.—Girl, aged 18 months, seen in consultation with Dr. J. S. Cohen. Her temperature was subnormal. Bottle-fed. Extremely weak and greatly emaciated. Voluntary movements slow and deliberate. Infant had received various food mixtures. None seemed to do good. Continuous gastro-intestinal disturbance. Bowel discharges were green and contained undigested curds. Child had been treated by several prominent pediatrists without effect. Condition becoming worse daily. Some vaginal discharge. Catheterized specimen of urine shows a trace of albumin and pus-cells. No casts. Urine high colored, scant and acid. Besides the marked emaciation the legs, thighs, lower abdomen and hands are edematous. Infant placed on Blockley buttermilk mixture with solid diet well salted and vegetable broth containing salt, olive-oil by mouth and cod-liver oil by inunction. Ordered to be taken out into the air and sun daily. It was given about 185 c.c. of warm sterile normal saline solution by hypodermoclysis every other day. The fluid was promptly absorbed. The urinary flow was greatly increased, the urine becoming practically colorless. The edema in the hands entirely disappeared as well as from the skin of the abdomen and thighs. The edema of the feet was not influenced to any great extent. A second examination of the urine revealed practically no abnormalities. It was impossible, however, to control the digestive disturbances. The number of bowel movements were increased and the child died suddenly from exhaustion about ten days from the beginning of treatment. This case, however, clearly demonstrated the non-toxic influence of sodium chlorid and large amounts of water in the presence of edema. The fatal ending of the case does not lessen the importance of this fact.

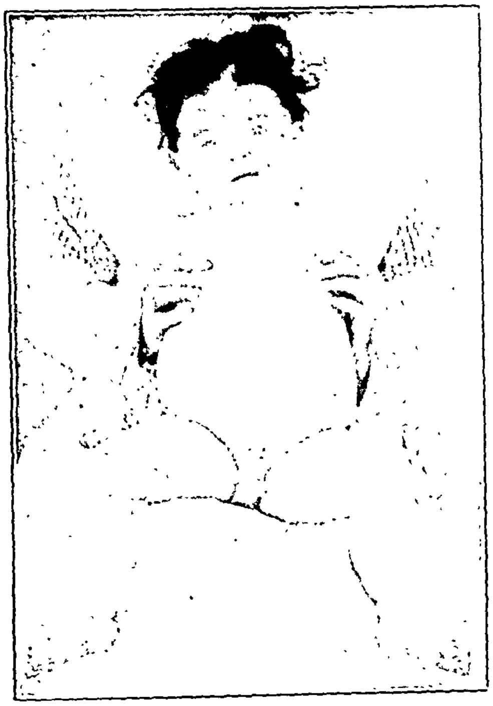

Fig. 3.—Acute nephritis. Marked edema of body (Case 8).

Case 4.—As in the previous case there was a fatal ending, but the symptom of edema as will be seen was materially lessened. The patient was Mrs. S. S., aged 52, a patient of Dr. Helen Kirschbaum who kindly permitted me to see her. This patient was desperately ill. She had exophthalmic goiter, with tachycardia, mitral regurgitation, cardiac dilation, arteriosclerosis and nephritis with edema of the legs, thighs and face. She had been ill for one and a half years. Patient was very excited and her condition was regarded as hopeless. Examination of the urine revealed the presence of albumin and casts. It was decided to inject 500 c.c. of the sodium carbonate and salt solution intravenously in order to note its effect on the edema. Following the injection the symptom was remarkably lessened. The urinary flow increased and the albuminuria lessened. She died, however, from cardiac exhaustion. The effect on the blood-pressure was not appreciable.

Case 5.—J. R., boy, aged 8 years, admitted to my service at the Mount Sinai Hospital, May, 1913. Diagnosis, acute attack in a child with subacute nephritis. Illness is supposed to have started two years previously. Child ailing more or less during this time. Three weeks previous to admission mother noted puffiness of the eyelids and that the feet and legs were edematous. Appetite poor. Intense headache. Urinary flow said to be diminished. Urinalysis showed albumin and casts, red and white cells and intensely acid smoky urine with a specific gravity of 1.026. Treatment: The alkaline and salt solution were administered by the drop method by rectum. In addition this solution sterilized was given hypodermically under the skin of the abdomen. At the point of injection two severe sloughs later appeared. These took weeks to heal by slow granulation. Sloughing resulted in all probability from the action of the alkali, and I believe it unsafe to employ the solution in this manner. It should either be given intravenously or by rectum. Figure 2 shows the sloughing areas. Result: The edema, the albumin, casts and blood elements disappeared and the urinary flow was increased. The child left the hospital within two months perfectly well and was sent to the seashore to recuperate. There has been no recurrence. Final recovery was delayed on account of the sloughing sores.

Case 7.—G. L., aged 22 months, admitted to my service at the Mount Sinai Hospital, August, 1913, diagnosis nephritis. Infant markedly edematous about the body and face for the past two months. Vomiting and diarrhea. Urinalysis shows all the evidence of nephritis. Treatment: Sodium carbonate and sodium chlorid solution by drop method by rectum and normal saline solution by hypodermoclysis. Result: Discharged from the hospital, September, 1913, completely recovered.

Case 8.—H. C., aged 17 months, seen in consultation with Dr. Robin of Wilmington, Del., and later admitted to my service at the Mount Sinai Hospital. Diagnosis, severe nephritis. Breast-fed up to present time. About eleven weeks ago developed a rash which was diagnosed measles (probably was scarlet fever); several days later mother noticed that child passed no urine. The entire body, face, hands, arms, legs, feet, thighs, scrotum, abdomen and chest wall intensely edematous (Fig. 3). Examination showed some fluid in the abdominal cavity and thorax. The lungs showed some edema as well. Urine obtained by catheter became practically solid when boiled. Contained casts and blood elements and was intensely acid. Child received 200 c.c. of normal salt solution under the skin and enteroclysis by the sodium carbonate and sodium chlorid solution. Treatment was continued daily, the amount injected being from 150 to 250 c.c. The edema began to decrease rapidly, but the urinary flow was not increased and the amount of albumin remained the same (Fig. 4). The abdomen and scrotum became more distended and the child became weaker and died three weeks after admission. This child was actually water-logged. The kidneys were damaged beyond repair as judged by the tremendous amount of albumin. While the edema, especially that involving the face, legs and scrotum almost entirely disappeared, the urinary flow was not increased. Fischer's explanation as to why certain nephritics increase in weight after receiving salt in the food in all likelihood applied here. The giving of salt causes the edematous tissues to give up their water. This cannot escape via the kidney if it be too severely dam-

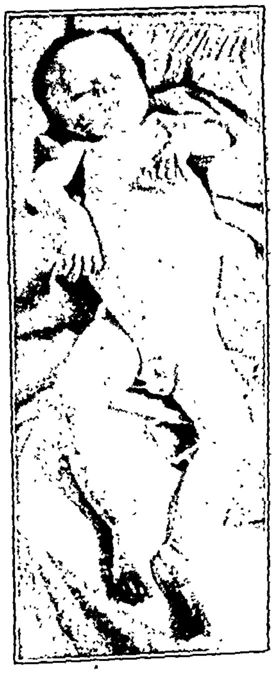

Fig. 4.—Edema of body much less (Case 8) after several injections of salt solution.

aged. Hence the fluid collects in the cavities, and being a solution of colloidal substance, it cannot be absorbed. Hence the increase in weight. This occurred in this case. This also explains why tapping must be done in this type of patient.

CASE 9.—E. S., girl, Pole, aged 8 years, seen in consultation with Dr. J. J. Frankel. Following a frank attack of scarlet fever the child developed an intense nephritis and when first seen was unconscious, in convulsions and edematous. The urinalysis presented all the features of acute Bright's disease. The sodium chlorid and sodium carbonate solution were given by the drop method by rectum continuously for about ten days together with salt solution by hypodermoclysis. The child remained unconscious for three days and was fed through the nose. She finally made an uneventful recovery, all the symptoms of nephritis disappearing and to-day she is perfectly well.

CONCLUSIONS

My experience with this method of treatment permits me to subscribe to the following:

1. Sodium chlorid neither produces nor increases water retention in either the nephritic or non-nephritic.
2. It is curative in cases of edema from any cause provided the kidneys are not too severely damaged.
3. It does not cause edema in marantic infants.
4. When combined with an alkali and plenty of water it exerts a benificent influence on all the symptoms of nephritis.
5. It is dangerous to administer a solution of an alkali under the skin as it is liable to produce sloughing.
6. The best means of administering the salt and alkali solution is either by rectum or intravenously.

1927 North Broad Street.

ABSTRACT OF DISCUSSION

DR. THOMAS S. SOUTHWORTH, New York: I cannot speak from the point of view of this disease in children, but since the use of sodium chlorid in children is contradictory to what has been impressed on us so strongly in late years concerning the elimination of salt from the diet of nephritic patients, I think it is wise to speak of the use of Fischer's solution in the case of a young adult with typhoid. She began with acute nephritis and delirium. There is no question of the fact that the nephritis rapidly cleared up coincidently with the instillation of Fischer's solution into the rectum, by the drop method. Whether it had any beneficial effect on the nephritis or not, it could not be said to have had any deleterious effect.

DR. JOHN ZAHORSKY, St. Louis: Will Dr. Lowenburg state what is the difference between giving from 10 to 15 gm. of potassium acetate or sodium chlorid by mouth every three hours, and then drinking a lot of distilled water or plain water, and using the solution hypodermically or by rectum? It is painful and often produces sloughing to introduce this material under the skin.

DR. PERCIVAL NICHOLSON, Ardmore, Pa.: When I was a resident in the Municipal Hospital we treated a large number of patients with salt solution by bowel, and we found it markedly increased elimination, and lowered the mortality in toxic cases of diphtheria. We devised a method to run the salt solution in slowly and continuously, only intermitting two hours during the day. At the end of the first day the children hardly noticed it, and retained the solution well even though a number were under 2 years. Solution introduced by the bowel seems to act better than when introduced by mouth, for the reason that the stomach is not upset with large quantities of solution. With the proper apparatus it is easy to administer by rectum, without disturbing the patient.

DR. HARRY LOWENBURG, Philadelphia: Dr. Zahorsky is right. Alkalies by mouth are just as good as salt administered by rectum. The paper emphasized the fact that salt did not increase the severity of nephritis, nor increase edema. I think salt administered directly would probably bring about as good results. Absorption may not be as quick.

THE RÔLE OF FUNCTIONAL KIDNEY TESTS AND PREOPERATIVE AND POSTOPERATIVE TREATMENT IN THE REDUCTION OF PROSTATECTOMY MORTALITY *

B. A. THOMAS, A.M., M.D.
Professor of Genito-Urinary Surgery in the Polyclinic Hospital and College for Graduates in Medicine
PHILADELPHIA

Conspicuous among the many notable urologic achievements characterizing the close of the nineteenth and the dawn of the twentieth centuries stands the establishment of prostatectomy—or more properly speaking prostatic adenomectomy—as a feasible, desirable and comparatively safe operative procedure. The surgical treatment of adenomatosis of the prostate, alias prostatic hypertrophy, has changed most remarkably since the days of Mercier's incisor and Leroy d'Étiolle's valvular section of the neck, to the modern conservative perineal operation of Proust-Young or the suprapubic transvesical prostatectomy of Fuller-Freyer.

Although it is generally conceded that the mortality due to danger of infection from catheter life in prostatism, in those cases in which that form of treatment is possible or justifiable, is to-day at least twice as great as from a skilfully performed prostatic adenomectomy, the fact exists that for more than a decade following the first so-called total prostatectomy in 1891 by Goodfellow, the death-rate incident to this operation was so high that the utility of the catheter continued to be an almost universal practice. During the past thirteen years mortality following prostatectomy has steadily decreased from 50 per cent. to from 5.5 to 3.77 per cent. in the experience of its worthiest and most expert exponents. In the light of these facts it is a source of much regret to genito-urinary surgeons that many practitioners on the one hand continue to advise and recommend, routinely, medical treatment and the time-worn catheter with its 100 per cent. mortality in a four-year prognosis, while on the other, many general surgeons doubt the veracity of statistics and point to a minimum mortality of from 10 to 20 per cent. for the operation of prostatectomy.

Satisfactory as the results have become with improvements in technic, there is to-day a definite and extensive effort on the part of urologists to shave the present low mortality by more careful discrimination in the selection of operative cases, by exact study of the general organic fitness of the candidate, especially his functional kidney sufficiency. Obviously the age of the patient cannot be entirely ignored, and weighed in conjunction with other features of the case, may preclude the advisability of operation, although *per se* advanced age is no contra-indication. Other factors of equal importance governing the operability of the case are best appreciated by recalling the stages of the living pathology of prostatism, namely (1) dysuric phenomena, (2) retention of urine with or without infection, (3) distention and dilatation of the bladder incident to urinary obstruction and (4) internal compression of the kidney with secondary cardiovascular changes and toxemia leading to uremia.

---

* Read before the Section on Genito-Urinary Diseases at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

Thus in addition to the offending prostate itself, with its secondary and remote organic and systemic effects, in the capacity of renal, cardiac, pulmonary, hepatic and even nervous and mental defects, infection is commonly present and must receive consideration in the prognosis and preliminary preparation of the patient. The increased mortality of prostatectomy in cases complicated by infection or calculi is well recognized.

As a result of the cardiorenal involvement, which is invariably present to a greater or lesser degree in cases of prostatic obstruction, I have come to attach much importance to the determination of blood-pressure and have made it a routine part of the preparatory study of all cases, placing its importance second only to the estimation of the renal function.

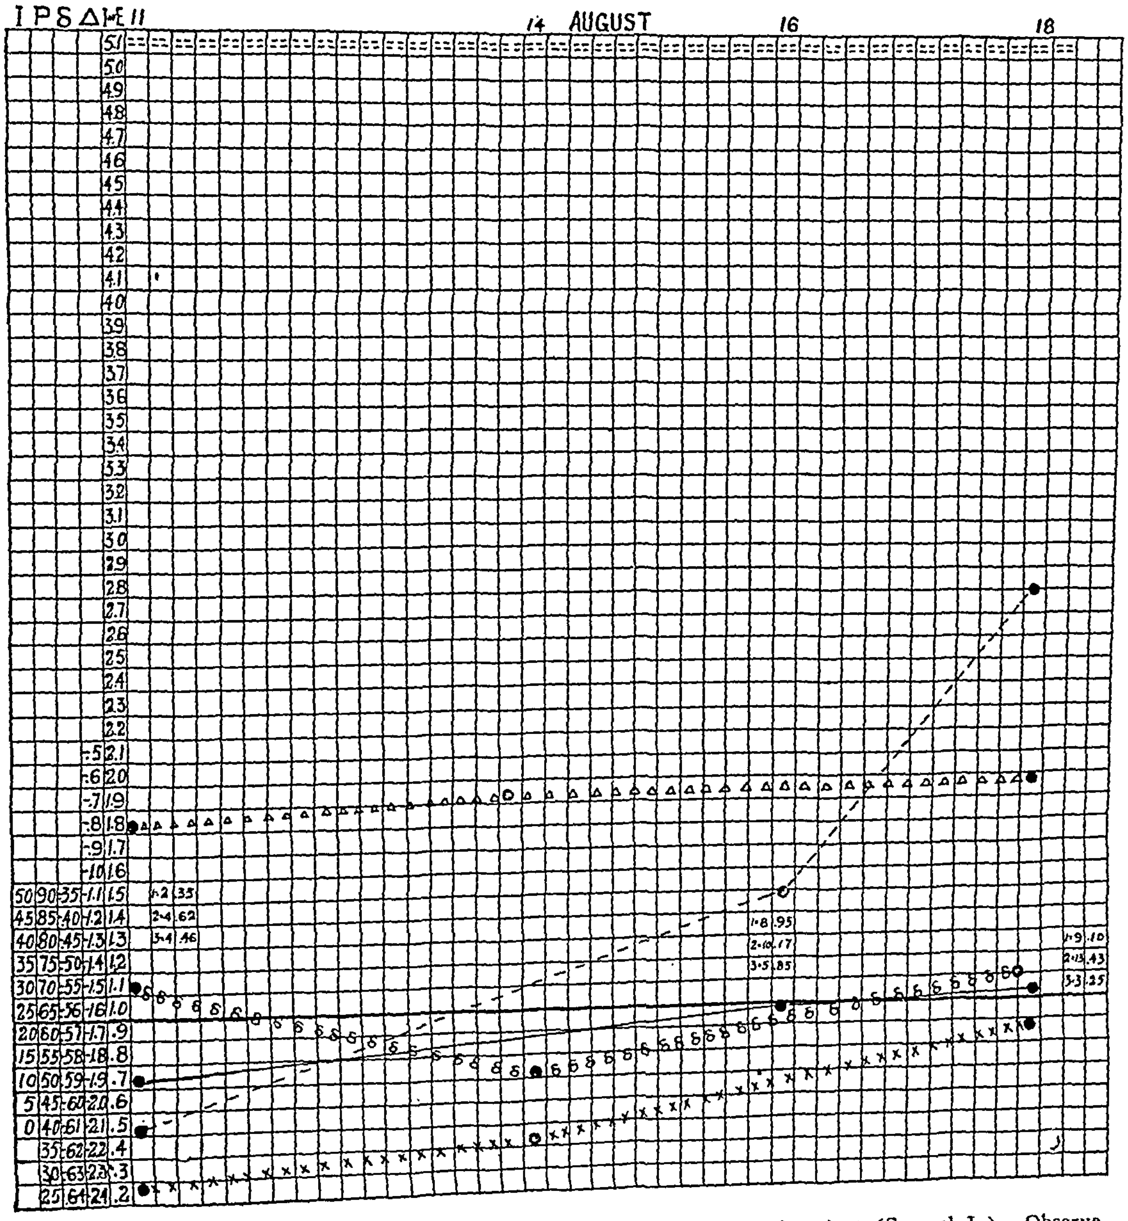

Fig. 1.—Illustration of progressive improvement in organic condition of patient (Samuel L.). Prostatic adenomectomy followed by uneventful recovery. Observe especially index of elimination of indigocarmin. — — — — = index of elimination of case (indigo); = = = = = average normal index for indigo; ——— = indigo percentage elimination; xxxx = phthalein percentage elimination; δδδδ = cryoscopy of blood; ΔΔΔΔ = cryoscopy of urine.

In importance at least equal to the blood-pressure governing the operability of the case stands the myocardium associated or not with a cardiovascular sclerosis. Minor valvular lesions of the heart in themselves need not be considered as vital contra-indications. Operation has been denied to two patients because of cardiac lesions associated with high blood-pressure and general sclerosis, in spite of the fact that in both cases the renal function was ideal as determined by indigocarmin, phenolsulphonephthalein and cryoscopy.

It must be quite apparent, therefore, that the factors concerned in the operation of modern prostatectomy and responsible for making its mortality one of the mildest in urologic surgery are manifold. They may be grouped advantageously under three captions: first, the preoperative investigation and preparation of patients; second, improvement in technic, and third, the best postoperative treatment. It is my humble conviction that the first and third steps in the management of the case are vastly more important than the operation itself and certainly outweigh any decision as to the choice of the perineal or suprapubic route.

Before entering on any discussion of the operative technic, I wish to revert for a few moments to the preliminary investigation of the case. Rectal palpation is of as much importance in urology as is a vaginal examination in gynecology; therefore, this exploration becomes the first act with the patient presenting a prostatic history. The second act consists in the determination of the amount of residual urine. This is important prognostically, in view of the *vis a tergo* pressure on the kidneys incident to the urinary retention and especially in determining the degree of actual vesical distention, for when the amount of residual urine attains, and *a fortiori* when it exceeds 300 c.c. the musculature has become atonic and the bladder has been strained and permanently dilated. This is evidenced by the deplorable result of prostatectomy, however skilfully performed, when vesical contractility is abolished.

The evil effect of completely evacuating the bladder in cases of marked retention of urine are well recognized by urologists. Not only may congestion and hemorrhage from the bladder and kidneys occur following such a procedure, but shock and even sudden death may supervene, owing to the reflex nervous derangement of long tolerated intrarenal pressure and secondary cardiac involvement. An understanding of this pathologic mechanism readily explains certain phenomena of urinary secretion, particularly the results in functional kidney tests when the elimination preceding sudden evacuation of the bladder in cases of retention markedly exceeds at times that after vesical relief. To perform prostatectomy or any other major surgical operation at that time, when the patient is in the negative phase, as it were, is equivalent to signing his death certificate and has deterred the wise surgeon from removing the prostate at the time cystotomy became necessary for urinary drainage. This realization, the provocation of preliminary treatment by catheterization, is by all odds the most important factor in the reduction of prostatectomy mortality. The value of this step has prompted a few genito-urinary surgeons to recommend the two-stage operation in all cases. I feel that such a practice routinely is utterly unnecessary, although the exceptional case will demand the procedure. As a rule intermittent catheterization or the catheter *à demeure,* closed, but opened from time to time, or allowed to drain continuously, will suffice for drainage for vesical and renal *restitutio ad integrum.*

During the period of preoperative treatment, particularly if urinary infection is present, total irrigations with silver nitrate are imperative, attention to the gastro-intestinal tract is obligatory, copious drafts of water associated with urinary antiseptics in an attempt to increase the urinary output are of great value, and finally, many patients will be braced up and tided over the critical operative stage by the internal administration of such drugs as strychnin, digitalis, nitroglycerin, caffein, sodio - benzoate, spartein and acet - theocin sodium (theophyllin sodio-acetate).

Undoubtedly, the study of the renal function is of preeminent importance, since impairment of the kidneys, resulting in azotemia and uremia, kill more patients after operation than any other organic defect and is the *raison d'être* of many known and unknown subsequent pathologic conditions.

It is my practice to subject all candidates for prostatectomy to a rigid and extensive investigation of their kidney function. Frequently these examinations have to be repeated owing to the poor operative risk at the time of admission, so that the average patient is obliged to remain in the hospital for his preoperative treatment for a term of two or three days to as many weeks or months in exceptional cases.

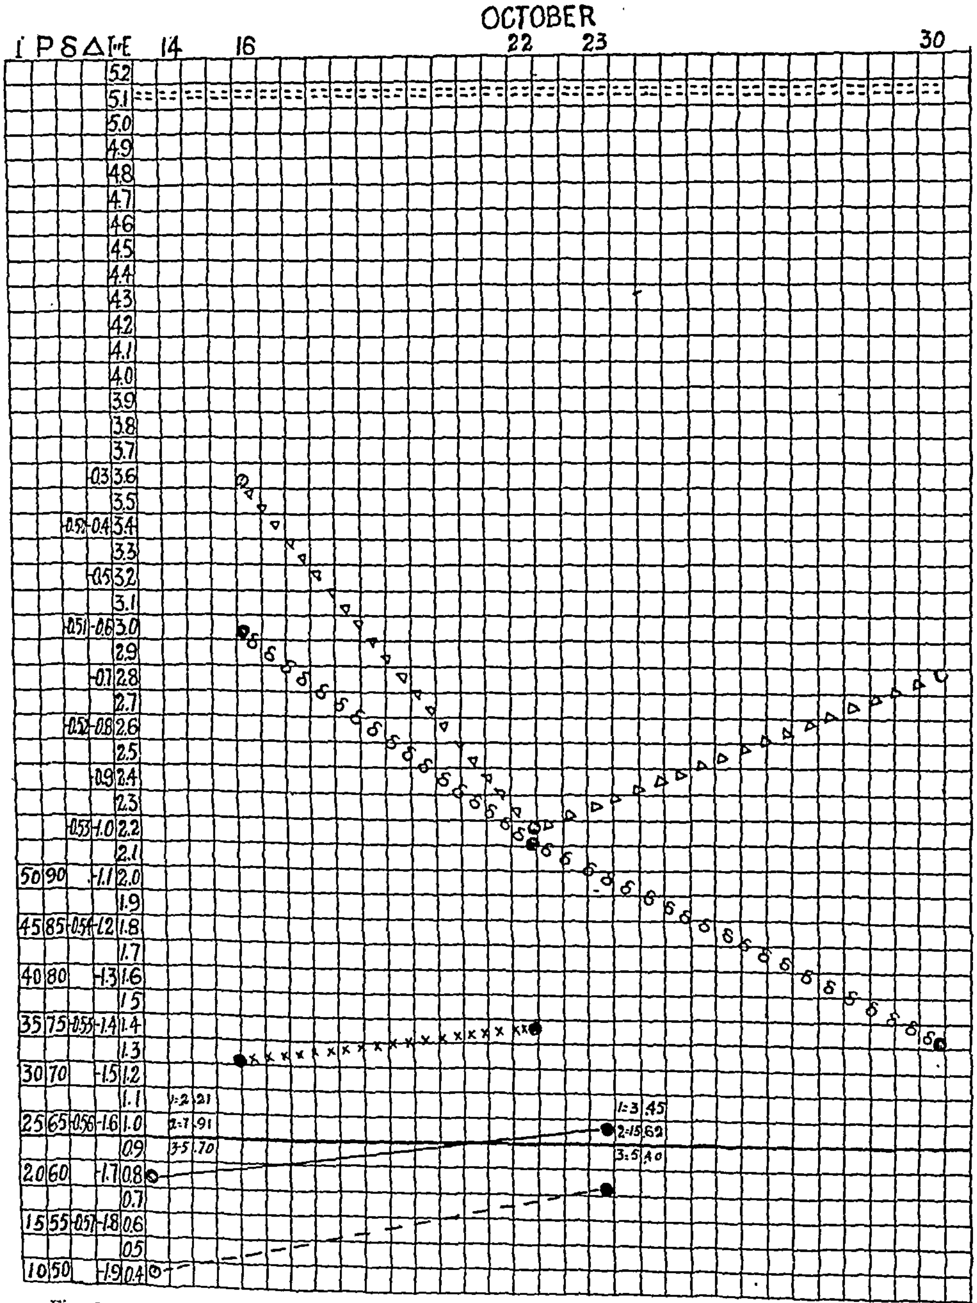

Fig. 2.—Case of inoperable prostatic adenomatosis (Michael T.). Inoperability due largely to marked cardiovascular lesions in addition to renal insufficiency. = = = = = average normal index for indigo; — — — — — = index of elimination of case (indigo); ———— = indigo percentage elimination; xxxx = phthalein percentage elimination; δδδδ = cryoscopy of blood; ΔΔΔΔ = cryoscopy of urine.

The functional kidney tests routinely employed are indigocarmin, phenolsulphonephthalein, cryoscopy of the blood and urine and the determination of urea. Of these an extended experience has taught that indigocarmin is the most practical and best and in no way superseded in value by any of the others. It matters little whether deductions are drawn from the onset of elimination or made from quantitative colorimetric determinations. The dye may be administered either intramuscularly or intravenously; if by the latter method, which may be the preferable procedure, there is no resultant soreness at the site of injection—an objection which was raised against the intramuscular method.

Valuable as I believe indigocarmin to be as a functional kidney test, judged from its onset of elimination and quantitative determination, I have been recently deeply interested in working out what I have styled its *index of elimination*. In the careful study of a series of cases, normal and pathologic, it is apparent to me both from the clinical point of view and operative results, that the *index of elimination* furnishes a truer guide as to the renal function than any other method that it has been my pleasure to utilize. The *index* is determined by dividing the quantity of indigocarmin eliminated during the first hour by the quantity excreted during the third hour after injection. Realizing that when the kidney parenchyma is diseased the onset of elimination is delayed and the amount of early elimination proportionately diminished, while the duration of excretion is prolonged, it has seemed to me for a number of years that the relative outputs for the first and third hours was of prime importance and probably of greater value than the mere quantitative output for the first two hours.

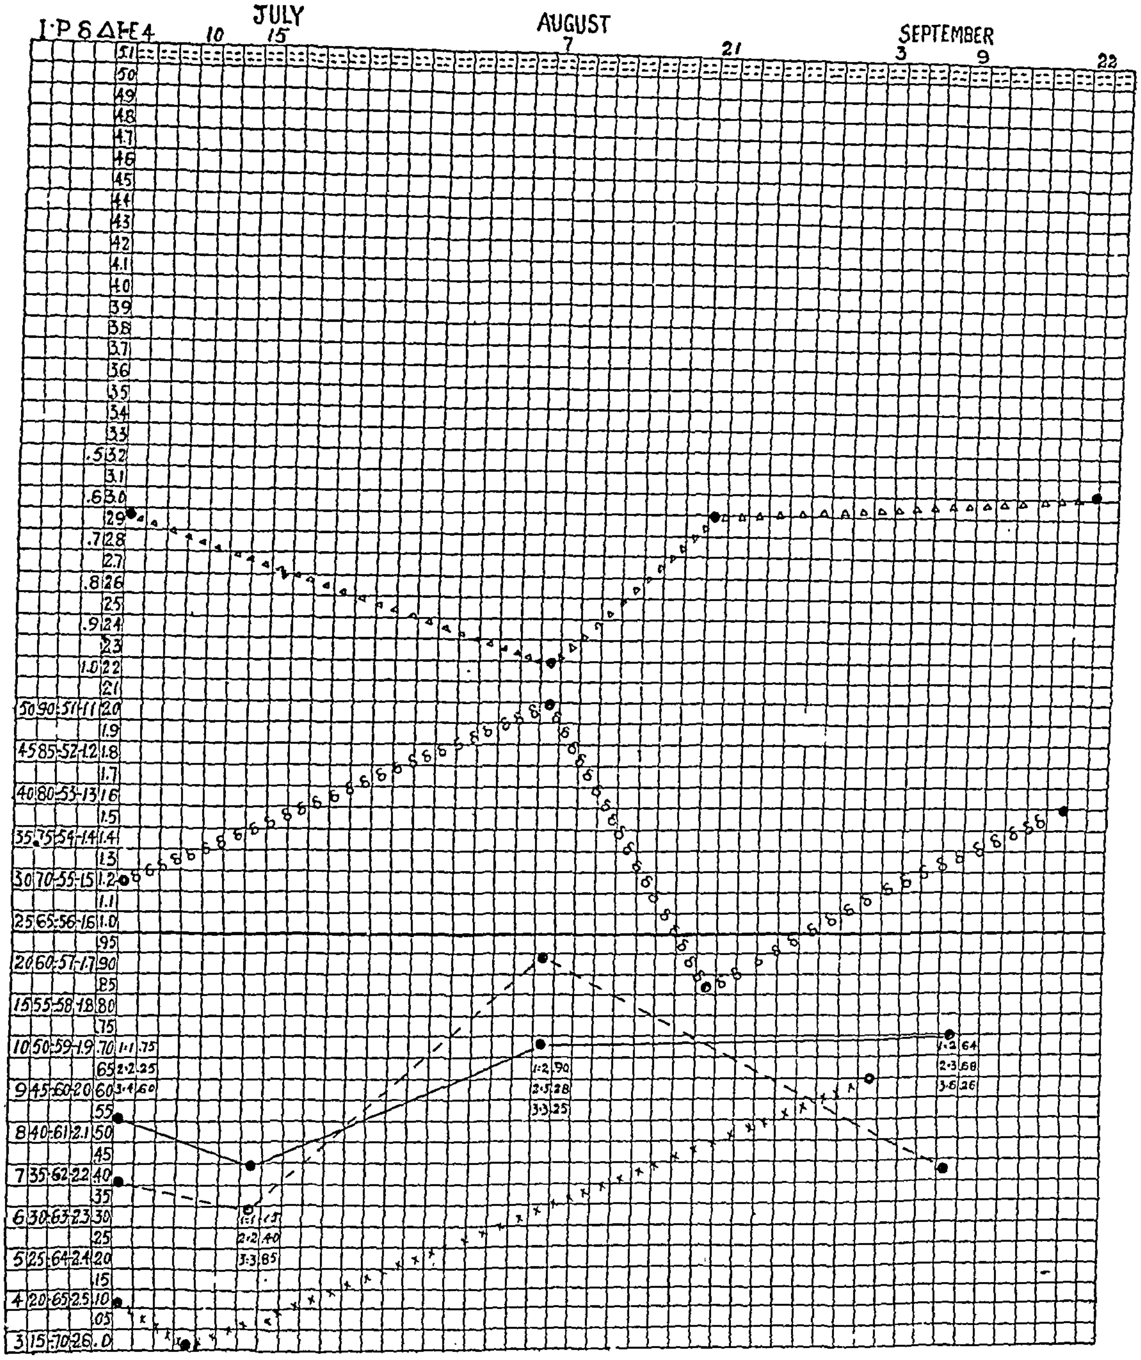

Fig. 3.—Case of inoperable carcinoma of prostate (Augustus C. V.). Observations extend over three months until death. = = = = = average normal index for indigo; — — — — = index of elimination of case (indigo); ——— = indigo percentage elimination; xxxx = phthalein percentage elimination; δδ δδ = cryoscopy of blood; ΔΔΔΔ = cryoscopy of urine.

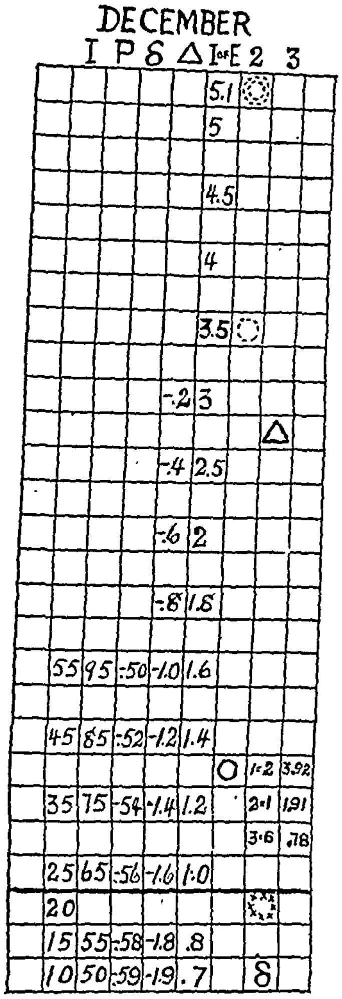

Fig. 4.—Index of elimination of indigocarmin high. Prostatic adenomectomy with recovery (Isaac F.). Circle of double broken lines = average normal index for indigo; circle of single broken lines = index of elimination in case (indigo); solid circle = indigo percentage elimination; circle of x's = phthalein percentage elimination; δ = cryoscopy of blood; Δ = cryoscopy of urine.

In order to substantiate my claims and belief, I have introduced into this article a number of self-explanatory charts of prostatic cases, inoperable, operable and operated, illustrating the position and value of the *index of elimination* relative to the quantitative determination of indigocarmin as well as various other functional kidney tests (Figs. 1, 2, 3, 4, 5, 6, 7 and 8). I have determined that the *index of elimination* for normal individuals in a series of cases averaged 5.1, and have designated same by double broken lines. A study of the charts graphically impresses the fact that when the amount eliminated during the third hour equals or exceeds that excreted during the first hour, the patient's kidney function possibly contra-indicates serious operative intervention, namely, prostatectomy, unless the total amount eliminated in three hours exceeds 20 per cent., when operation may be considered even though the *index of elimination* be very low (Fig. 6).

The importance of thoroughly emptying the bladder by catheter at the end of each hour cannot be too strongly emphasized, otherwise erroneous results will occur.

Relative to operative technic or the choice of operation itself, time, space and inclination forbid that I shall say much. It is my belief that the prostatectomist who patronizes exclusively the perineal route is just as much in error as the surgeon who dogmatically attacks the prostate only suprapubically. Worst of all is the operator who chooses this or that route simply because he can do it better, regardless of a lower mortality by another method, of which he may be less familiar; such surgery may be the best for the operator but not necessarily for the rank and file of patients. The fundamental consideration in the choice of routes for prostatectomy should be the selection of that associated with the minimum mortality. Presumably this, as demonstrated by its ablest exponent, Hugh Young, is perineal prostatectomy, and it behooves each prostatectomist to familiarize himself with every minute detail of technic of the conservative perineal operation before casting his lot unalterably with the suprapubic route. The operative approach in each case should be governed more by the pathologic condition present than by the normal anatomic relationship of the prostate. To attempt the removal perineally of a prostate with preponderant enlargement of the median lobe, particularly if it be complicated by a large vesical calculus or possibly a neoplasm, is just as erroneous a procedure as the attempted enucleation suprapubically of a small fibrous, adherent gland,

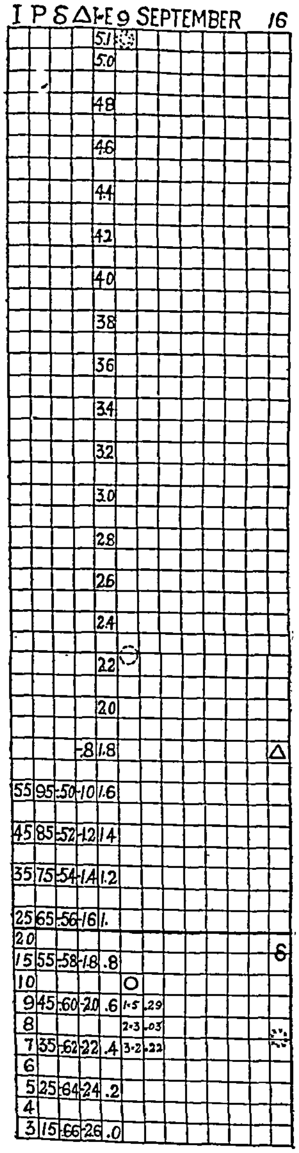

Fig. 5.—Index of elimination high, indicating operability of case. Prostatectomy followed by uneventful convalescence (Freeman S.). Circle of double broken lines = average normal index for indigo; circle of single broken lines = index of elimination in case (indigo); solid circle = indigo percentage elimination; circle of x's = phthalein percentage elimination; δ = cryoscopy of blood; Δ = cryoscopy of urine.

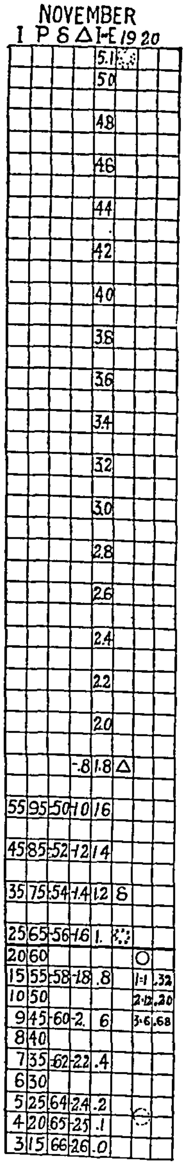

Fig. 6.—Index of elimination very low, but case pronounced operable since total output of indigocarmin for three hours exceeded 20 per cent. Prostatectomy and recovery (Albert M.). Circle of double broken lines = average normal index for indigo; circle of single broken lines = index of elimination in case (indigo); solid circle = indigo percentage elimination; circle of x's = phthalein percentage elimination; δ = cryoscopy of blood; Δ = cryoscopy of urine.

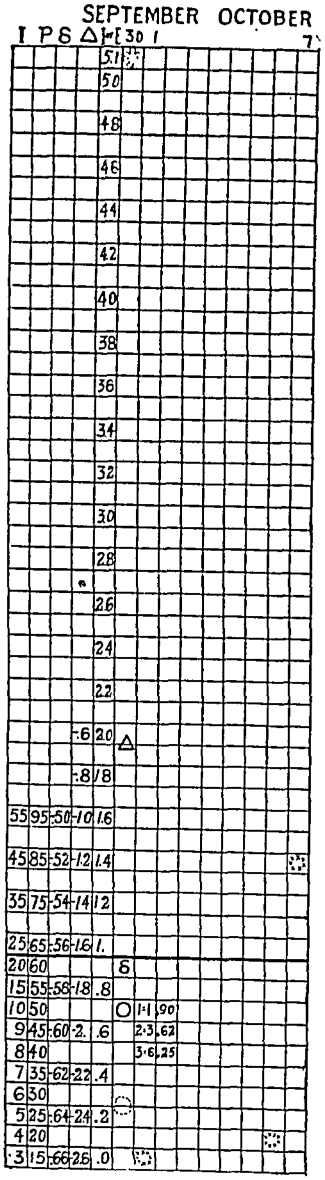

Fig. 7.—Index of elimination demonstrates insufficiency of kidneys and contra-indicates prostatectomy (Mr. A.). Circle of double broken lines = average normal index for indigo; circle of single broken lines = index of elimination in case (indigo); solid circle = indigo percentage elimination; circle of x's = phthalein percentage elimination; δ = cryoscopy of blood; Δ = cryoscopy of urine.

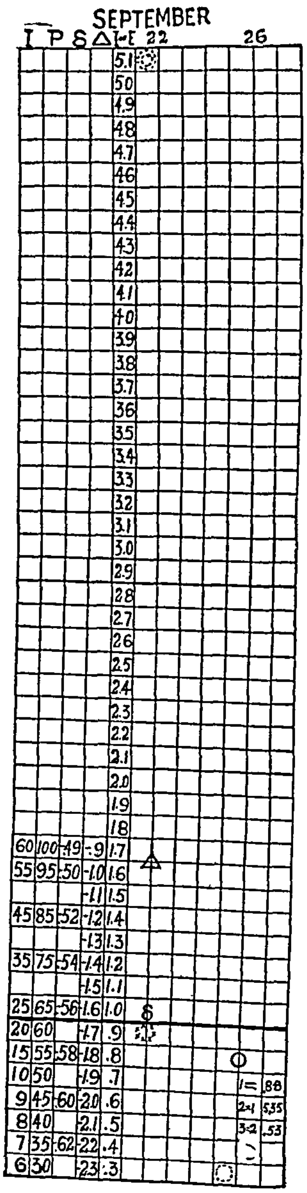

Fig. 8.—Illustrative of case of organic insufficiency in which index of elimination of indigocarmin contra-indicated prostatectomy (David S.). Death seventeen days after operation. Circle of double broken lines = average normal index for indigo; circle of single broken lines = index of elimination in case (indigo); solid circle = indigo percentage elimination; circle of x's = phthalein percentage elimination; δ = cryscopy of blood; Δ = cryoscopy of urine.

ofttimes readily excised perineally. To me it has seemed and is the routine practice to decide each case for itself, whether the prostate is to be attacked perineally, suprapubically or perurethrally. A most important aid in determining this choice has been the cystoscope. By it the nature of the lobular hypertrophy, vesical complications as calculus, tumor, etc., and most important of all, the functional integrity of the kidneys are determined (Figs. 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19 and 20). As a result of this discrimination in a series of over thirty cases only 16.6 per cent. of the patients were operated on suprapubically. Four patients, as a result of careful organic investigation, particularly the renal function, were refused operation. Moreover, the series embraces three cases of carcinoma — one pronounced inoperable (Fig. 3), and the other two discovered during the histopathologic examination of the removed gland—and one case of sarcoma. A review of all operated cases, both perineally and suprapubically, excepting one patient who died of ether pneumonia on the ninth day after prostatectomy, shows a mortality of 3.3 per cent. I feel morally certain that the death-rate in this series would have reached at least 10 per cent. had not the four patients noted above been refused operation owing to their organic and renal insufficiency.

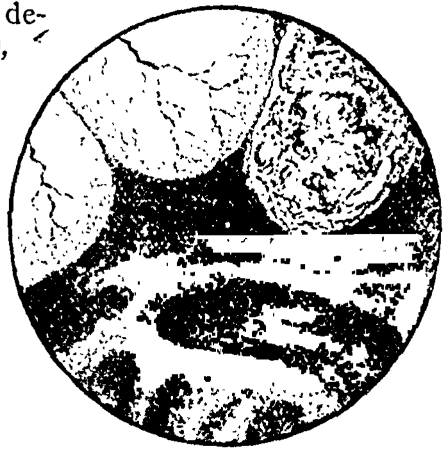

Fig. 9.—Ulcerative myxosarcoma of prostate.

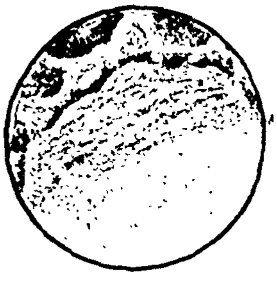

Fig. 10.—Hypertrophy of median lobe of prostate with beginning carcinomatous degeneration.

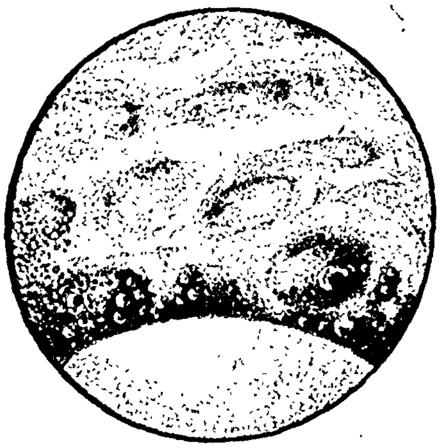

Fig. 11.—Prostatic enlargement complicated by vesical calculi.

It can be readily inferred from the statements above that, all things being equal, prostatectomy by the perineal route is the operation of preference. The technic employed follows as nearly as may be that advocated by Young, the essential difference being the incision as shown in Figure 21. In the employment of the suprapubic method, the technic of Freyer, with minor modifications, is utilized.

Although nitrous oxid is the preferable anesthetic in desperate cases, the gas-oxygen-ether sequence may be routinely and safely employed, particularly if due preliminary urinary drainage has been secured and properly maintained until the susceptibility of derangement of cardiovascular and nervous mechanisms incident to the *vis a tergo* intrarenal pressure has passed.

The postoperative treatment of these old men is little less important than the preliminary preparation. The cardinal factors responsible for speedy convalescence and a minimum mortality-rate are, first, hydrotherapy (routine hypodermoclysis and continuous vesical irrigation), and second, position (sitting posture in and the next day out of bed at the earliest opportunity).

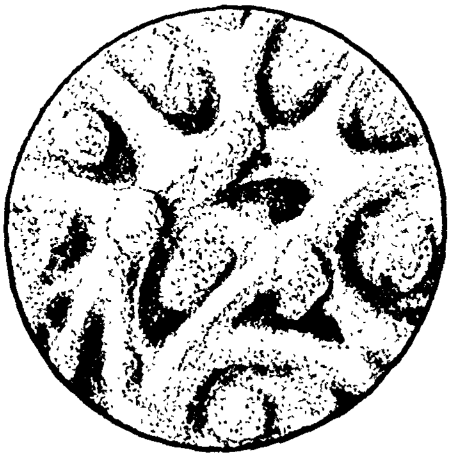

Fig. 13.—Trabecular hypertrophy of bladder and multiple papillomas complicating prostatic hypertrophy.

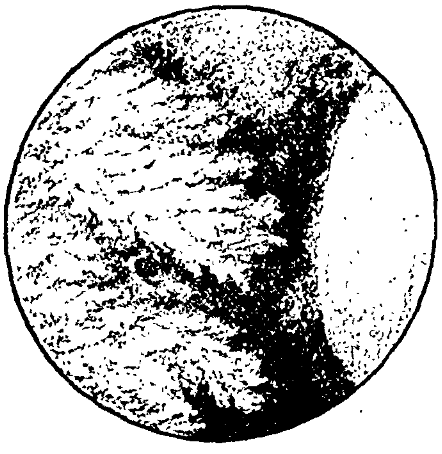

Fig. 14.—Papilloma of bladder complicating enlargement of the prostate.

CONCLUSIONS

1. The most appropriate method of prostatectomy in a given case depends on the pathologic condition present, rather than on the normal anatomic relationship of the prostate. This pathologic condition is of greater consideration than the statistical low mortality-rate of either the perineal or suprapubic method, and more discrimination in this respect offers a means of shaving even the present low percentage. The cystoscope is a most important aid in the determination of the avenue of approach in the particular case.

2. Although the renal function is the paramount consideration in determining the operability of a case, consideration of other organic conditions must never be slighted.

3. Indigocarmin is superseded by no other kidney test in the estimation of the renal function.

4. Apparently of more dependence than merely the onset and quantity of excretion of indigocarmin is the *index of elimination,* described by me.

5. A prostatectomy mortality of 3.3 per cent. is attributed largely to cystoscopic aid in determining the method of operation, and also to the *index of elimination* of indigocarmin in discrimination as to the operability of cases.

116 South Nineteenth Street.

ABSTRACT OF DISCUSSION

Dr. Hugh H. Young, Baltimore: I have never tried this method that Dr. Thomas has brought forward. It is certainly ingenious. Will Dr. Thomas say whether there is a similar index in phthalein? Do they stand in about the same proportion? I think we are all rapidly coming to the view that there is no one method; we do not think that phthalein is the only thing to use. Certainly a study of the blood, in a good many ways, is important, and we also must back up our laboratory findings with the clinical. A certain percentage of output in the first or second hour is not dependable. In a great many cases a man will never reach the stage at which his functional output would be considered good. In those cases the important thing is whether the output is stable so that the patients will be in a condition to stand operation. There are patients who go through an operation although their output is poor. Perhaps Dr. Thomas' suggestion as to the index may be of value, and I would like to see it worked out for all the other functional tests. I want to congratulate him on his low mortality. There is no doubt that the functional tests and preliminary treatment are important factors in lowering mortality. I feel that it is unnecessary in the large majority of cases to use a suprapubic drain. I employ that very seldom. I almost always use either a retained catheter or intermittent catheterization.

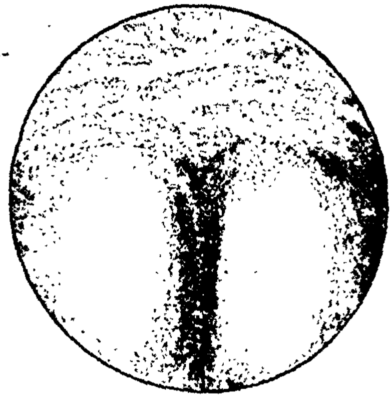

Fig. 15.—Preponderant hypertrophy of lateral lobes of prostate.

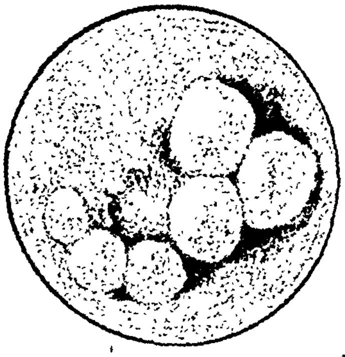

Fig. 16.—Vesical calculi and ulcerative cystitis complicating prostatic enlargement.

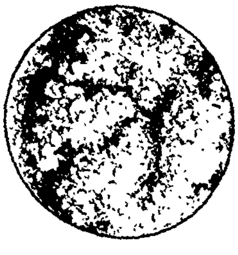

Fig. 17.—Carcinoma of bladder complicating prostatic hypertrophy.

Dr. Edward Martin, Philadelphia: I have seen Dr. Thomas' accurate work and I know its thoroughness. He is a lover of indigocarmin, is jealous of the claims of all other tests, and, as a result, applies his favorite test with more discriminating judgment than does any other man in this country. Certainly, in his hands, it is efficient and reliable. For the untrained the sulphonephthalein would seem more available.

Dr. Martin Krotoszyner, San Francisco: I am much interested in Dr. Thomas' statement as regards the choice between the suprapubic and the perineal route on the basis of cystoscopic findings, and I hope that Dr. Thomas will dilate on this point in closing the discussion.

Dr. Hugh Cabot, Boston: The longer I use tests of various kinds the more clear it becomes to me that dependence on one test is unsound. I have not come to the same conclusion as Dr. Thomas with regard to indigocarmin. I regard it as markedly inferior to phthalein. The essential thing is stability of kidney function, rather than a high or low function, which influences our opinion. We have all seen patients with extremely low function, tested in various ways, but without evidence of nitrogen retention, who stood operation well because the function was still stable. We have also seen patients with high function which, under various strains of exercise, changes of diet and alterations in the quantity of water, would vary markedly. Those patients we regard as extremely poor risks, and unless their kidney function can be made stable they are going to cause us to let the other fellow operate. I believe that some method of studying the nitrogen retention of the blood is essential to the most narrow decision in these cases. There are cases in which in no other way can one determine impending uremia. We have been depending largely on the Folin method of determining the nitrogen content of the blood. The French are using a pretty complicated method, but they all aim in the same direction—the evidence of the ability of the kidney to get rid of nitrogenous products. None, I think, of the color tests or the test with phloridzin attains that extremely important point. I am inclined to classify phloridzin, indigocarmin and phthalein in the same general category, regarding phthalein as the most efficient and the most easily managed, but all of them necessarily controlled by a study of nitrogen retention in the more difficult cases.

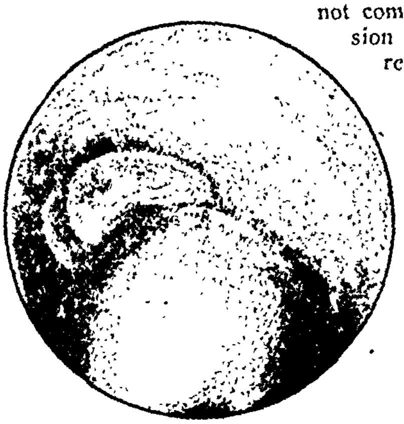

Fig. 18.—Vesical calculi and preponderant hypertrophy of median lobe of prostate.

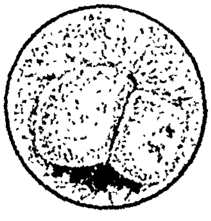

Fig. 19. — Vesical calculi complicating prostatic hypertrophy.

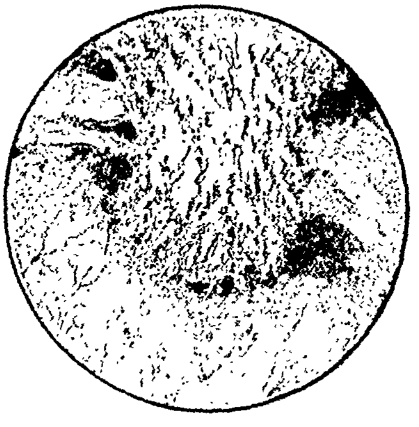

Fig. 20.—Papilloma of vesical neck complicating prostatic enlargement.

Dr. F. W. Braasch, Rochester, Minn.: I am not very familiar with the use of indigocarmin and therefore do not know its comparative value. I do not believe, however, that any functional test can give us data which will determine whether or not to operate. It has been my experience that subjective symptoms and clinical data following preliminary treatment are determining factors.

Dr. B. A. Thomas, Philadelphia: That it is not the large output that counts is exactly my contention. That is the very reason, as I said, that the total output for the first and second hours is not comparable in utility, from my experience in over three hundred cases, to the index of elimination or the ratio of the total output of the third and first hours. Concerning the index of elimination for phenolsulphonephthalein about which Dr. Young asked, there is no doubt but that the same method can be applied to any substance. It has, however, been my experience that the index thus determined has not been so reliable as when applied to indigocarmin. I have long thought that there may be the same objection to phthalein as to phloridzin, that is, the test may be too delicate; certainly the results in my experience are not so uniform and apparently not so reliable. Respecting the comparable value of indigo and phthalein, I would like to direct your attention to the chart of the patient with inoperable carcinoma of the prostate. You will see that phathalein indicated progressive improvement in the state of the patient's health. Indigocarmin total output showed that he was barely holding his own, while the index of elimination of indigo showed that the patient all the time was gradually sinking farther down into the negative phase. I could show you a number of other instances in which indigocarmin has apparently served as a much more reliable guide than phthalein. Brevity of time precluded the possibility of entering on the advantages of the cystoscope in determining the best operative procedure to be adopted in cases of prostatic hypertrophy. There are few patients who cannot be satisfactorily cystoscoped, and the revelations it gives are instructive and important. If you have a patient with a preponderance of the middle lobe, and particularly if associated with a large calculus or a vesical tumor, it is folly to attempt to remove that prostate perineally. On the other hand, if it is small and hard, with no relative preponderance of middle-lobe enlargement, it is perhaps wise, in view of the lesser mortality, to attack it perineally.

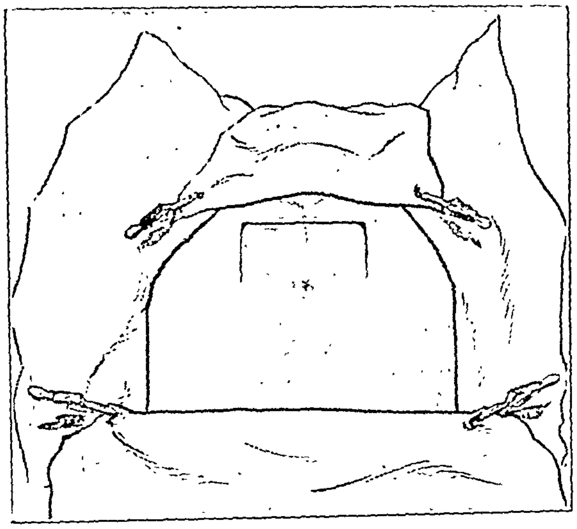

Fig. 21.—Author's incision.

Speaking of mortality, in explanation of the low mortality of 3.3 per cent. which I have had, I attribute this perhaps to good fortune, but also to certain other factors and precautions. For instance, in the last year I have refused to operate on four patients on account of the revelations by indigocarmin, and I am convinced that had I operated in those cases my mortality would have been 10 or 15 per cent. at least.

Finally, I believe that this index of elimination may give a better idea of the stability of the renal function than mere quantitative determination for the first two hours of indigocarmin or phenolsulphonephthalein, but in my experience it has been applied with the best results to indigocarmin.

THE RELIEF OF STERILITY BY MEANS OF PERMANENT EPIDIDYMOSTOMY

WITH THE FORMATION OF AN ARTIFICIAL SAC FOR THE STORAGE OF THE SPERM *

V. D. LESPINASSE, M.D.
CHICAGO

The types of sterility suitable for permanent epididymostomy are all cases of obstruction of the vas above the internal abdominal ring, and almost all cases of obstruction of the ejaculatory ducts. This work represents seventy-nine operations.

The relief of male sterility attracted little attention until 1901, 1902 and 1903, when Martin,[1] Scaduto[2] and Bogoljuboff[3] published their works on anastomosis of the vas to the epididymis, and the rete testis to the vas. These operations give excellent results in proper cases, but the statistical frequency of cases of sterility suitable for them is about one in three, or 33 per cent. They depend absolutely on the patency of the vas deferens. If the vas, or ejaculatory duct, is stenosed they fail.

To try to relieve the cases with a stenosed vas deferens, I conceived the following technic: A sac was made communicating with the epididymal tube lumen into which the sperm could be discharged and hence accumulate, so that the individual would always have from 2 to 10 c.c. of sperm available at all times. Two points came up: First, Where, or rather what portion of the epididymal tube is best suited to discharge into this sac? The head of the epididymis was selected as the most available portion as it is practically always open. It has the disadvantage, however, of having the smallest lumen of any portion of the epididymis. Second, How and of what shall the sac be composed? An ideal sac must possess the following characteristics: Material for its construction must always be available. It must be non-absorptive. It must not secrete any substance that is harmful to the sperm. As material for the sac, I have tried peritoneum, bladder mucosa, skin and rubber sheeting, and have under way experiments using vein silver foil and celloidin.

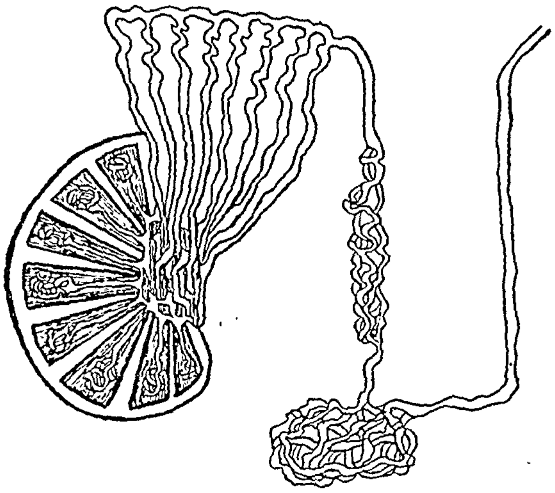

Fig. 1.—Schematic drawing showing the testicle, rete testis, globus major, body of the epididymis, globus minor and the vas deferens.

* Read before the Section on Genito-Urinary Diseases at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

[1] Martin: Univ. of Penn. Med. Bull., 1902, p. 388; ibid., 1903, xv, 2; Therap. Gaz., Dec. 15, 1909, p. 837.

[2] Scaduto: Ann. d. mal. d. org. génito-urin., 1901, xix, 257.

[3] Bogoljuboff: Arch. f. klin. Chir., 1903, lxx, 648.

When this work was first conceived, I considered that the technic would be very simple and could be carried out with great ease. The first difficulty encountered was the adherence of the parietal layer of the tunica vaginalis to the cut surface of the epididymis. I then considered all the methods of preventing peritoneal adhesions, but before these were carried out Post's[4] article on peritoneal adhesions came out, and he showed conclusively that all the so-called standard methods were practical failures. He advanced a new method, namely, the use of sodium citrate 2 per cent. in 3 per cent. salt solution.

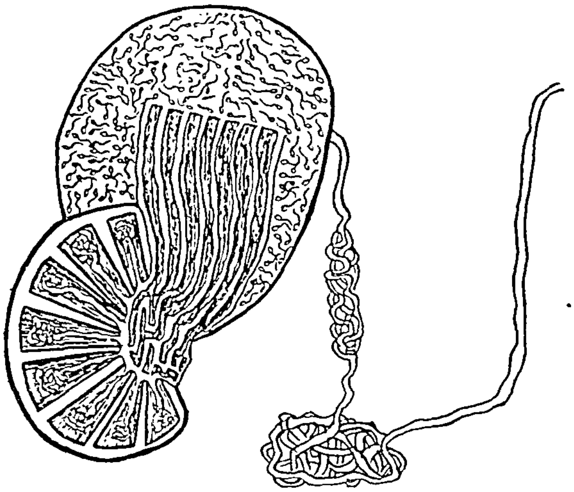

Fig. 2.—Schematic drawing, same as Figure 1, except that it shows the tubule of the globus major cut off and the sac made around them filled with spermatozoa.

This was tried and failed. In the peritoneal cavity there is considerable movement between the visceral and parietal peritoneal surfaces. In this work on the epididymis there is practically no movement, which fact may explain our failures.

I thought that these adhesions might be prevented by treating the tissues as we do the intima of blood-vessels, but these methods failed. The reason for this failure, in my opinion, is the slight hemorrhage that comes from the cut epididymal tubules and the absence of motion between the epididymis and the parietal layer of the sac. To check this hemorrhage, or at least minimize it as much as possible, I used epinephrin. Then it was thought that we might operate without producing any hemorrhage from the epididymis at all by the use of the following technic: A human hair threaded on a fine blood-vessel needle was passed into the lumen of the epididymal tubules; it was run along the lumen about a millimeter or so, then the wall of the tube was pierced by the needle and the hair brought outside the tubule; the two ends of the hair were then tied, so producing a slightly elastic band which would gradually cut through the tissues. On the side of the sac, to obviate adhesions to the cut surface of the epididymis, I desided to try some non-absorptive epithelial surface such as skin, bladder mucosa, or a piece of vein or artery. Only two of these tissues are available from a practical point of view, namely, skin and a section of vein. Skin was used with considerable success. Then, after becoming acquainted with the work of Delbet[5] on the use of rubber, it was thought that the sac might be made of rubber.

This was carried out in three ways:

First, making the sac of tunica vaginalis and then simply covering the cut surface of the epididymis and the continguous surfaces of the testicle and epididymis with a piece of thin rubber sheeting.

Second, by making the sac entirely of this sheet rubber and sewing it to the reflected capsule of the epididymis.

Third, by removing the tunica vaginalis completely and placing the entire testicle and epididymis in a rubber bag and sewing this bag to the spermatic cord.

TECHNIC

The tunica vaginalis is exposed as for an ordinary operation for hydrocele. The parietal layer of the tunica vaginalis is then cut, thus exposing the testicle and the epididymis. Epinephrin is now injected beneath the capsule of the epididymis, commencing at the top of the globus major and continuing down to the junction of the globus major with the body of the epididymis. An incision is made in the center of the epididymis commencing at the top of the globus major and continuing down to the junction of the globus major with the body of the epididymis. The epididymal capsule is now dissected off, thus exposing the epididymal tubules. The tops of these tubules are now cut off or hair threaded through them. The sac is made as follows: The rubber sheeting or tunica vaginalis is sewed to the reflected capsule of the epididymis in such a manner as to form a closed sac. The testicle is now replaced in the scrotum and suitable dressings applied.

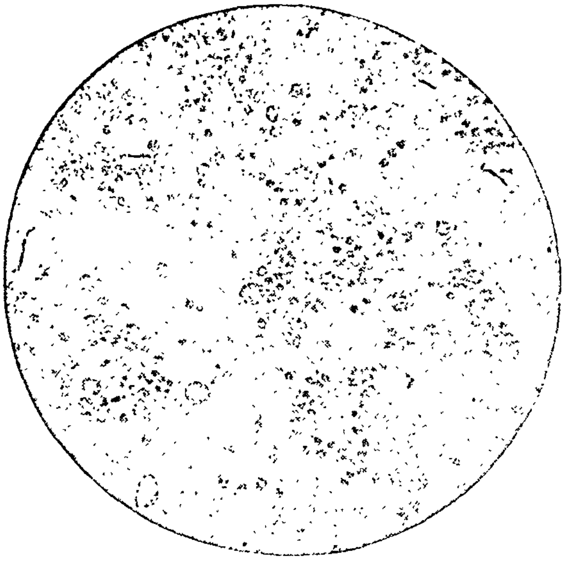

Fig. 3.—A photomicrograph of the fluid aspirated from the sac. This shows numerous spermatozoa.

CONCLUSIONS

With the above-described technic we can produce a sac into which the sperm will discharge and continue to live. This sac can be tapped whenever sperm are desired for impregnating purposes. This operation will relieve all cases of male sterility in which there is a functionating testicle.

I am under obligation for assistance to Drs. B. Newton Novy, Eugene J. O'Neil, John A. Ritze and S. Eisenstaedt, of the Laboratory for Experimental Surgery of Northwestern University Medical School.

ABSTRACT OF DISCUSSION

Dr. Henry L. Sanford, Cleveland, Ohio: Has Dr. Lespinasse had any practical results? Has he cured any of these patients?

Dr. W. M. Spitzer, Denver: Dr. Lespinasse's attempt is something that ought to have been undertaken long ago. If Dr. Lespinasse has had results the experiment is going to be well worth trying. He says that the spermatozoa are motile. Are they motile after being mixed with prostatic fluid, or just at the time when he drew them from the sac? Has he attempted impregnation with this fluid, and what was the result?

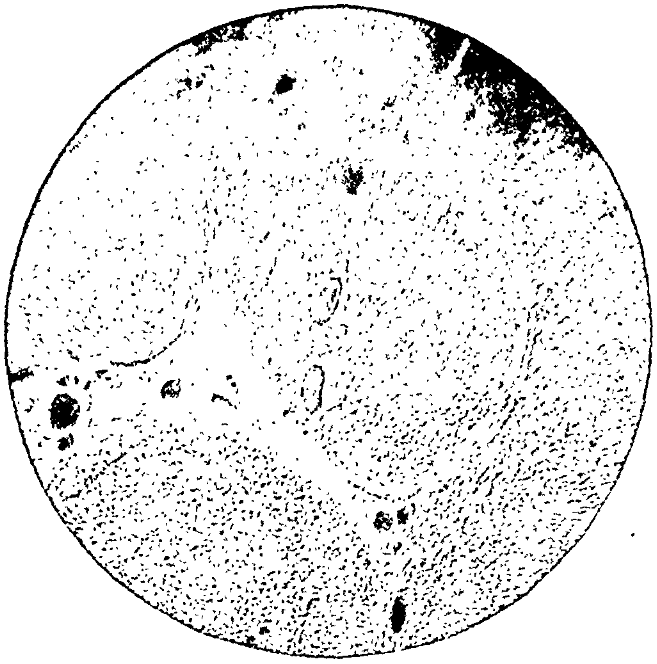

Fig. 4.—The hair in the epididymal tubule lumen. The two oval bodies are the cross-section of the hair.

Dr. Herman L. Kretschmer, Chicago: Will Dr. Lespinasse say what becomes of the rubber sac? Does it stay or slough out, or is it necessary to remove it?

Dr. Edward Martin, Philadelphia: These types of sterility come to us all, and we have not yet solved the question. I think everyone who has worked along this line has endeavored during operation to extract living spermatozoa, and usually the technic is their direct artificial injection into the uterus. There has as yet never been one single success. Lespinasse's suggestion seems a good one. In laboratory work we find that silver is tolerated better than rubber. A silver tube or capsule will remain and cause less irritation than rubber. It might be that a silver tube would be more likely to accomplish permanent drainage. This is suggested by the fact that in the operation of vaso-epididymostomy when we used silk on account of the frequency with which silver broke, our successful result fell at once, and when we went back to the silver we again got about 50 per cent. of successes. Within the last year I have reoperated in three cases, two of my own and one in another city. I used silver in these three cases. One is too recent to report on, but two of these patients reoperated on with silver have been successful, and in one case a pregnancy occurred afterward. The woman had a miscarriage, but the spermatozoa persisted in quantity.

Dr. V. D. Lespinasse, Chicago: There has been absolutely no practical application made of this procedure. I have been held up on it. When I first thought of this work, I thought it would be technically very easy to make this sac and to carry out the procedure. I found there were a good many points to be considered. This work represents seventy-two operations and twenty-three technics. The making of the sac is the hard part. I have three patients now who are waiting and anxious. One man calls me up once every month and wants to know how the dogs are. As soon as I get back home I am going to get some practical experience on him. It is an old idea that the spermatozoa from the epididymis are not motile. In my own experience they are practically all motile without admixture of prostatic fluid. If the operation is done aseptically, the rubber seems to heal in place nicely. If there is the slightest infection, the rubber will slough out. The results of artificial insemination have been excellent in the hands of such men as Bozzi and Iwanoff, who were willing to take the time and trouble to do this work in the proper manner. Bozzi obtained nine impregnations out of eleven attempts, the Iwanoff impregnated animals practically every time with sperms taken from the head of the epididymis.

THE DIRECT METHOD OF INTRALARYNGEAL OPERATION*

CHEVALIER JACKSON, M.D.

PITTSBURGH

In presenting the subject of the direct method of intralaryngeal operation, I do not wish to be considered as championing any particular method. Every laryngologist should be familiar with every method and select for operation in the particular case the method which suits best his personal equation for that case.

The indirect, or mirror, method can be used only in adults. Its greatest disadvantage is that in the guidance of the forceps it requires a movement backward when the image shows that a movement is needed forward, and for a diagonal motion it is necessary to combine a reversed anteroposterior movement with a true lateral movement. In the direct method, all movements are under the control of the eye and are made directly. This does not mean, however, that practice is not required. Many difficulties are to be overcome by continual practice before safe and accu-

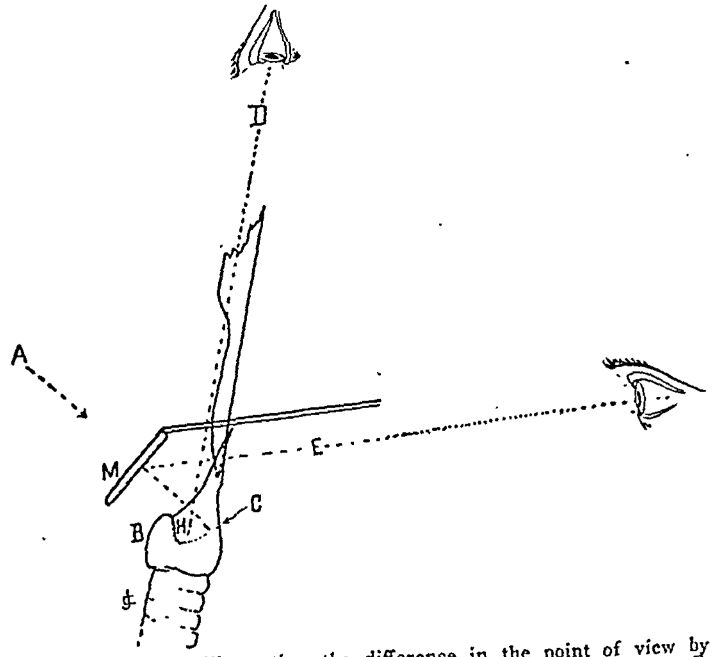

Fig. 1.—Schema illustrating the difference in the point of view by the direct and the indirect method. The observer's visual axis at *E*, looking into the mirror, *M*, gets an image as if he were looking from a point of the patient's head, *A*.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

rate operation is possible. To begin with, the gaging of depth by one eye only presents much the same problem as in indirect operating. All general considerations and the control and cooperation of the patient, as considered by my associate, Dr. Curtis, are, of course, equally applicable to the direct method. One point that seems not to be so well understood as it should be is the fact that the direct method affords a different point of view from that obtainable by the indirect or mirror method, which will be readily understood by reference to the schema, Figure 1. Moreover, the larynx being more or less drawn on, the upper orifice is elongated, the aryepiglottic folds are rendered more prominent, the epiglottis is invisible, being hidden by the tube, and the larynx is seen at its true depth instead of foreshortened as with the mirror.

In operations for any form of stenosis of the larynx in children, such as papillomas, subglottic edema, post-tracheotomic and postintubational stenosis, etc., the safety, promptness and accuracy with which intralaryngeal operation can be performed places direct laryngoscopy on a plane of advantage equaled only by its usefulness for diagnosis in these conditions. Great care must be taken in all endolaryngeal operations, direct or indirect, to impair laryngeal motility as little as possible, because as I have demonstrated, it is the tugging of the arytenoid on the cicatricial tissue that is the most important factor in the development of an adventitious vocal band.

Anesthesia.—For adults, I prefer local anesthesia with an 8 per cent. cocain solution supplemented by a few touches with a minute quantity of 20 per cent. solution to the interior of the larynx. In a few cases, for operations of extreme nicety, such as the plastic formation of adventitious vocal cords, and for the removal of benign growths which are obliterated by the ischemia produced by cocain, a general anesthetic may be necessary in adults. In children, the use of a general anesthetic in any case of stenotic laryngeal disease is extremely dangerous, because respiratory arrest is practically certain to follow as soon as the patient is sufficiently under the anesthetic to lose the aid of the voluntary accessory muscles of respiration. Tracheotomy, or what is very much better, the prompt insertion of a bronchoscope with artificial respiration and bronchoscopic oxygen insufflation, will save the patient's life; but in view of the hazardous nature of general anesthesia in this particular class of cases, which is out of proportion to the dangers of general anesthesia in the usual run of cases, I have always urged strongly in favor of no anesthesia. Cocain is extremely dangerous in children and as I have abundantly demonstrated, endolaryngeal operation is not painful and is so quickly done that anesthesia seems a needless risk. Particularly dangerous is the combination of chloroform and morphin, which are synergistic in the paralysis of respiration.

Position of the Patient.—For adults, under local anesthesia, the sitting position is preferable. Both patient and operator sit on stools, the patient being slightly lower than the operator. Sitting behind the patient is an assistant who supports the head preventing its rotation and preventing the patient from throwing the head backward (Fig. 3). If left to himself, the patient will naturally throw his head backward into the position of a man about to be shaved in a barber chair, which makes exposure of the larynx extremely difficult. An extreme forward position of the head and neck without excessive extension is preferable. The recumbent position is preferable in children. In operating on children without anesthesia, I have one nurse hold the knees of the patient down on the table; another nurse holds down both wrists, and the first assistant holds the patient's head high in the Boyce position of moderate extension. The degree of extension is less important than the very high position of the head (Fig. 4).

Instruments.—The operator should try all the different forms of instruments and illumination in order that he may take advantage of the particular instrument that best suits him in the particular case. I prefer the distally illuminated laryngoscope. The choice of instrument, however, is of less importance than that the operator shall have had adequate practice with it. For general operative purposes, I have found nothing superior to the tissue forceps shown in Figure 2, which have the great advantage of biting into the lateral wall with much greater facility than any form of sliding-punch forceps; lateral pressure cannot be made on a punch forceps, whereas the jaw of the tissue forceps will drag it laterally into the bite. I use duplicate forceps so that a fresh pair is handed to me immediately without delay for disengaging the extracted growth from the "basket" of the first forceps used.

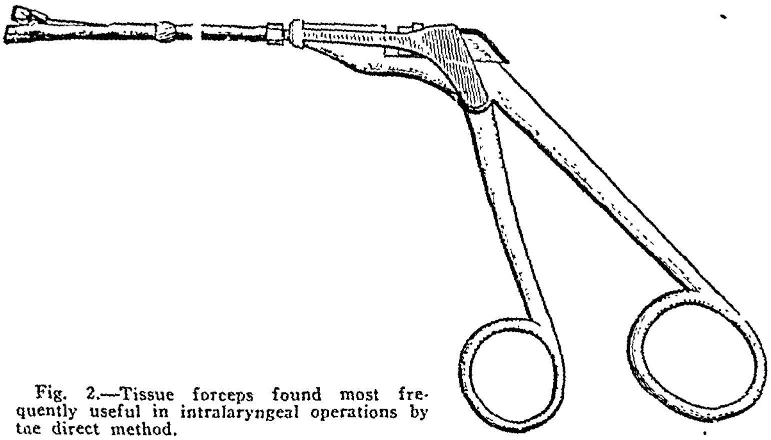

Fig. 2.—Tissue forceps found most frequently useful in intralaryngeal operations by the direct method.

Asepsis.—While we cannot sterilize the field, the patient's mouth should be thoroughly cleansed with a tooth-brush and rinsed with alcohol in 20 per cent. solution, which is the best non-toxic antiseptic. The patient's head is covered with a sterile cap having an opening opposite the mouth and the operator and all his assistants go through the regular operating room sterilizing technic. The operator should wear a mask for the protection of himself as well as the patient and should provide himself with protective glasses, or his regular glasses, in duplicate, to facilitate cleansing and replacement when spattered.

Technic. — To operate efficiently with forceps requires the coordinate movement of the left hand holding the laryngoscope, leaving the right hand free to use the forceps. In order to acquire this knack of coordination, it is necessary always to practice exposing the larynx, even when done only for diagnosis, with the left hand, never with the right. If this be done, not only is coordinate use of the laryngoscope and forceps in operating acquired, but the left hand develops the knack (rather than the strength) required for prolonged laryngeal exposure, should prolonged exposure ever be required.

Fist Stage.—The patient being in position shown in Figure 3, the operator, holding the laryngoscope in his left hand, while protecting the patient's lip by elevating it with his right index-finger, inserts the spatular extremity and depresses the tongue until the tip of the epiglottis comes into view (see schema, Fig. 5). Absolutely no effort should be made to see the larynx until the first stage of exposure and identification of the epiglottis is complete.

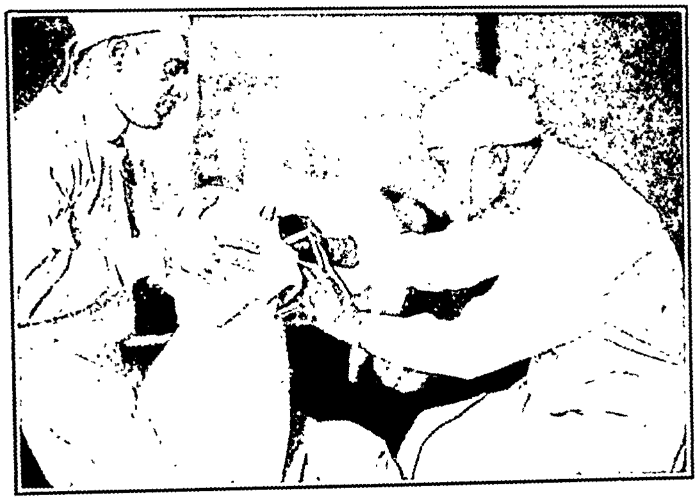

Fig. 3.—Position of adult patient and operator in intralaryngeal operation, first stage. After the epiglottis is exposed and passed, the patient's head is dragged downward and forward toward the operator.

Second Stage.—The spatular end is inserted slightly deeper, posterior to the epiglottis, being careful to keep the tube in the middle line, over the dorsum of the tongue. If the laryngoscope is inserted too deeply, the spatular end will get behind the arytenoid and the operator will be looking down toward the esophagus. In this event, it is necessary to start over again at the first stage.

Third Stage.—Exposure of the larynx consists in a downward and forward traction with the tip of the laryngoscope as shown by the dart in Figure 5. Under no circumstances should counterpressure be made on the upper teeth as a fulcrum. The patient's entire head must be pulled downward and forward with the laryngoscope.

Direct Laryngoscopy by the Lateral Route.—In the foregoing description, it is directed that the instrument be inserted over the dorsum of the tongue and kept in the middle line. This is essential until the operator has acquired the knack and is thoroughly familiar with all the landmarks. Considerable strength of wrist is necessary to cause displacement forward of the tissues attached to the hyoid bone, especially in stout and muscular subjects with short necks. In such patients it may not be possible to see the anterior commissure by that method. For all these reasons, I prefer the lateral route, passing the laryngoscope down at one or the other side of the tongue which rolls out to the opposite side and obviates the necessity of great displacement pressure. The side to be selected should be the one opposite to the involved laryngeal wall. By this lateral route, the anterior commissure can be exposed in any patient who can open his mouth, provided he be not allowed to throw his head backward, and provided the proper direction of traction downward and forward is maintained.

Removal of Growths from the Ventricle.—Growths whose origin is concealed in the ventricle are best exposed by the method which will be readily understood by reference to the schema, Figure 6.

Extubal Method.—For very large growths, the laryngoscope is used only to look through, the forceps being passed at the side of the laryngoscope and the closure of the jaws being under ocular control just beyond the tube mouth (Fig. 7).

Malignant Growths.—Following the initiative of Sir Felix Semon and Mr. Butlin, I have had such a high percentage of successes from thyrotomy in properly selected cases that I believe that to attempt endolaryngeal extirpation of a malignant growth would be a step backward. Therefore, endolaryngeal operation in malignancy is limited to the taking of a specimen for biopsy. For this purpose, the precision with which any desired portion of the neoplasm may be removed, along with sufficient normal tissue to give the histologist the best chance, has given to the laboratory report an approximate infallibility never before approached with the inadequate specimens usually obtained by indirect removal of a specimen.

Benign Growths.—In the removal of benign growths, the question arises whether it is better to slice the growth off even with the surface, or to bite into the apparently normal basal tissue. The first factor to be considered is the avoidance of any injury to the laryngeal motive mechanism. The arytenoids are particularly to be avoided and the muscular structures should be injured as little as possible. In case of growth involving the edge of the cord, it may be well to submit the matter to the patient for decision (Sanders), explaining to him that if the growths are sliced off even with the surface the chances of recurrence are greater than if removed more deeply, but deeper removal will temporarily impair the voice. Many patients will prefer a superficial removal, deferring more radical extirpation until recurrence takes place. This is especially true of professional voice users. Other patients dread the word operation and will choose radical removal as the best chance for avoiding a second operation.

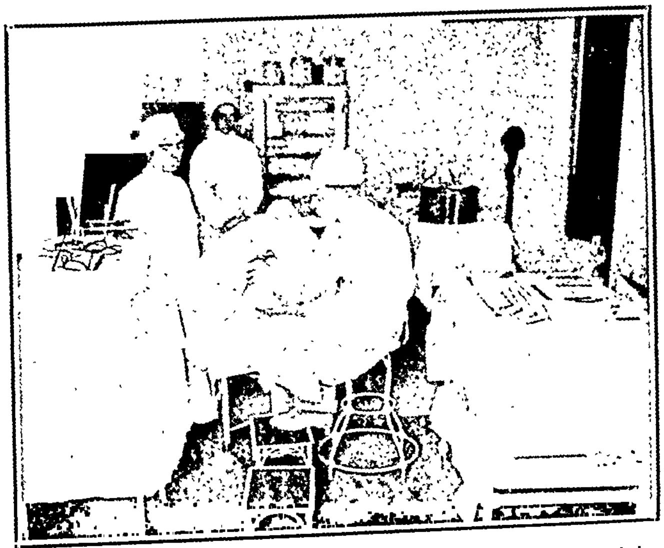

Fig. 4.—Position of patient and assistants for examination and intralaryngeal operation without anesthesia in children.

Papillomas.—Papillomas in children are by far the most common of all laryngeal growths. Thomas J. Harris[1] has had excellent results from the use of radium applied by the direct method.

---

[1] Harris, Thomas J.: Proc. Internat. Med. Cong., Sect. 15, London. 1913.

Harmon Smith[2] has had excellent results from fulguration.

The method which has yielded the best results in my clinic is removal with the forceps through the direct laryngoscope, repeated as frequently as necessary to nip off all recurrences in the bud. A little of the basal, apparently normal, mucosa is removed along with the growth. The superficially cicatricial mucosa which eventually results is an exceedingly unfavorable soil for the growth of papillomas, and recurrences cease after a number of removals. Occasionally a single removal is successful, a number of cases being known to be free from recurrence at the end of from one to eight years. In the majority of cases, however, many removals are necessary; but as they are done without any anesthesia, general or local, frequent operation at close intervals is unobjectionable. After a few sittings, most of the children do not resist or even cry. In the interval between operations, the local application of alcohol, as recommended by Delavan many years ago, hastens the hardening process. An alcoholic solution of salicylic acid, used by E. L. Jones, is also an excellent application.

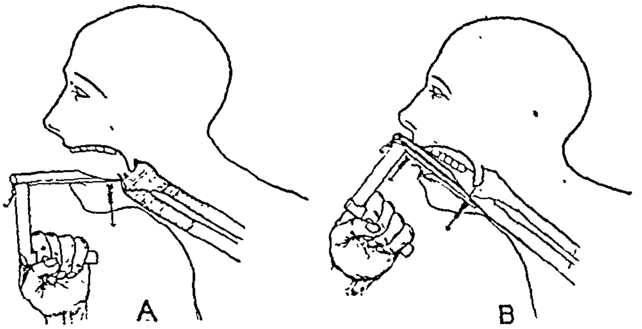

Fig. 5.—Schema showing the first and third stages of laryngeal exposure. At *A*, the tongue is seen depressed as indicated by the dart, causing the epiglottis to project into the line of vision. The second stage, not shown here, consists in a deeper insertion of the tube. At *B* is shown the third stage, the drawing forward of the epiglottis and all the tissues attached to the hyoid bone with the tip of the spatular end. The left hand is always used for holding the laryngoscope.

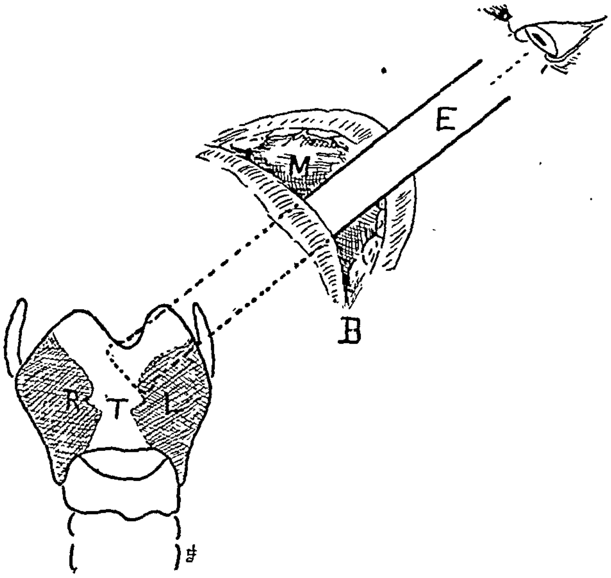

Fig. 6.—Schematic illustration of manner of exposing a tumor located in the laryngeal ventricle. The larynx is fixed by the hand of an assistant externally while the head of the patient is drawn down laterally to the side opposite the ventricle containing the tumor.

It is necessary to remember that there are two general classes of cases: In some instances a single removal is sufficient; in others a most stubborn tendency to recurrence is manifest, papillomas of children being more persistently recurrent than those of adults.

Laryngeal Stenosis.—Laryngeal stenosis, when hypertrophic in character, may be excised with the forceps when it overhangs the upper orifice of the larynx. Subglottic hypertrophic stenosis, as I have abundantly demonstrated, is readily amenable to galvanocautery treatment, the incisions being parallel to the long axis of the trachea and into the most prominent portion of the hypertrophy. Care should be taken not to cauterize deeply and not to touch the cords.

Laryngeal Tuberculosis.—Galvanocautery puncture for the treatment of laryngeal tuberculosis in all patients whose pulmonary condition is not too far advanced has yielded excellent results when indirectly applied by Heryng, Hajek, Mermod and Bar. Intralaryngeal applications as shown by Kahler can be made perpendicular to the surface by the direct method instead of the more or less linear application usually made with the mirror. This disadvantage of the indirect method can be overcome by using the right-angled point as advocated by Sir St. Clair Thomson.

Cicatricial and Congenital Webs of the Larynx.—Webs may be removed by the punch forceps provided there is a large redundancy of tissue. When the web is thin and tense, without redundancy, the incision with a view to the plastic formation of an adventitious vocal band, using the long straight direct laryngeal knife, will yield most excellent results as to the cure of the stenosis and restoration of the voice.

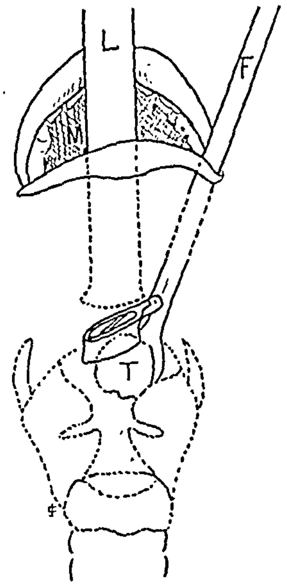

Fig. 7.—The author's "extubal" method for endoscopic removal of the epiglottis and growths originating in the upper orifice of the larynx. This method renders easy the removal of very large tumors that formerly required subhyoid pharyngotomy. It is not used for small growths. The forceps, *F*, seize the tumor, *T*, under guidance of the eye looking through the tube, *L*.

CONCLUSIONS

1. The direct method is the only one by which the larynx in children can be operated on.

2. The indirect, or mirror, method is applicable only to adults. The reversal of the image sagittally, without reversal laterally, compels the operator to develop the ability to move his forceps backward when the image appears to require the forward direction; and, more difficult still, is the necessity to combine for diagonal movement a reversed anteroposterior with a true lateral movement.

3. The difficulties to be surmounted by the direct method of intralaryngeal operation require prolonged and constant practice, but not nearly to the same extent as required by the mirror method.

4. No anesthetic, general or local, is necessary for operations on the larynx in children. In them, cocain is dangerous in any case, and general anesthesia is absolutely contra-indicated in all cases with even the

---

[2] Smith, Harmon: Laryngoscope, February, 1909.

slightest degree of laryngeal stenosis. Local anesthesia should be used in adults, general anesthesia, preferably with ether, being required only when cocain is contra-indicated or when the ischemia accompanying its use causes the growth to shrink to such an extent as to hinder accurate removal.

5. No one method can be said to be best for all cases and all operators. The laryngologist should try all methods and instruments so that he may decide for himself what best suits his personal equation and be prepared to use the method which, in his hands, is best adapted to the particular case.

6. Finally, any one who has the skill of Holbrook Curtis in the removal of benign growths by the indirect method, or of Thomas J. Harris in the indirect method of application of laryngeal galvanopuncture, will have no need of the direct method of intralaryngeal operation in adult patients.

Ninth and Penn Avenue.

INDIRECT INTRALARYNGEAL METHOD FOR REMOVAL OF BENIGN NEOPLASMS *

H. HOLBROOK CURTIS, M.D.
NEW YORK

In his book on diseases of the throat, Solis-Cohen[1] quotes two cases of removal of laryngeal growths through the mouth, one by Koderick of Brussels in 1750, the other by Green of New York in 1845. These were done in antelaryngoscopic days, but no details are given. In the literature, but seventy cases are mentioned before the invention of the laryngoscope. In Sir Morell Mackenzie's list of 100 cases of laryngeal tumors operated on by him, and reported in 1880, sixty-seven were said to have been papillomas. Of sixty-six consecutive cases operated on by Solis-Cohen, reported in 1871, forty-eight were assumed to be papillomatous in origin.

According to Cohen and Mackenzie, next in frequency occur the fibromas. Moritz Schmidt, however, quotes the frequency of fibromas to papillomas of the larynx in 32,997 clinical cases examined to be 256 to 46; they usually occur singly and are apt to be redder in color and are not usually pediculate. Myxomatous fibromas are usually larger, attaining the size of a Lima-bean or even greater. They are generally pediculate and paler in color; they may be globular or pyriform in shape, and occur on the epiglottis as well as on the cords. They are rarely encountered. True myxomas are also but seldom found. Sir Morell Mackenzie reports but one in his 100 consecutive cases of laryngeal growths. They are translucent semipink or reddish, and generally pediculate, varying much in size. Their most frequent seat is in the anterior commissure of the cord.

Angiomas are purple in color and occur on the ventricular bands and epiglottis, rarely on the cords.

Lipomas may occur on the arytenoids, epiglottis or ventricular bands. They are characteristic yellow tumors.

Cystomas may occur on the epiglottis or on the ventricular bands and more rarely on the cords. They are usually sessile, translucent and pale in color, and of semifluid contents.

Chondromas are made up of hyaline cells and are cartilaginous in origin, usually springing from the cricoid, thyroid, epiglottis or arytenoid cartilages.

Singers' nodules (chorditis nodosa) occur on the vocal cords at the junction of the anterior and middle third; they are usually bilateral and are composed of stratified epithelium.

Polypi present the appearance of the usual polyp.

Pachydermia are of epithelial origin and attain a much larger size than an epithelial nodule on the cord. They are found most frequently in the posterior portion of the cords, invading the respiratory tract. A peculiar characteristic seems to be that they are usually bilateral, and the conical apex of one fits into a depression in the other, or in case they are on one cord, the hard apex makes a corresponding depression in the other band.

Sarcomas present no especial feature to the unaided eye. Cohen states that removal of a benign growth through the mouth is much less apt to terminate fatally than through external openings and that recurrence is less likely to follow.

Sessile papillomas are apt to return after operative procedure, if the seat of the wound is not sufficiently cauterized after the removal of the growth. This may be accomplished by Tobold's concealed silver nitrate stick, or by chromic acid fused on a laryngeal probe.

The instruments used for removal of laryngeal growths by the indirect method have not been improved on very much since 1880. The methods of removal advocated by most writers include the forceps, cauterization by acids or silver nitrate, and by the galvanocautery. In the local treatment of papillomas, Dundas Grant has spoken well of the continued application of a 2 to 5 per cent. solution of salicylic acid in absolute alcohol, while Delavan has reported a case of multiple papilloma cured by a spray of absolute alcohol used six times daily.

In speaking of the growths which occur in the larynx, it is not my intention to advocate the indirect intralaryngeal method in their removal. I have been asked simply to demonstrate the possibilities achieved by deftness as a result of experience, and speak of the instruments which are generally employed.

Of the numerous instruments invented for the removal of laryngeal benign neoplasms, we must first mention the laryngeal snare of Carmalt Jones, and that of Gibb, and also the port-caustic of Jarvis, and that of Tobold, as well as the sponge probang first mentioned by Voltolini. Fauvel was the first operator to devise the laryngeal forceps, which were modified and improved by Sir Morell Mackenzie. These are described by Lennox Browne.[2] The guarded forceps of Dundas Grant is an instrument of special value in the removal of pediculate growths on the cords. The universal forceps of Watson Williams are in certain cases to be recommended. Sir Morell Mackenzie's cog-wheel ecraseur must not be overlooked nor the various snares of many other authors, described by Watson Williams.[3] Curets are of use in removing growths of a sessile variety, and those occurring beneath the anterior commissure. Heryng has constructed a variety of these, as have many operators. The Krause-Heryng double curet forceps[4] are used in

Europe, but seldom in this country. The first of this kind of forceps was invented by Stoerk, and modified by Schroetter, both of Vienna; Mackenzie,[5] who describes them in his text-book, also invented a tube forceps, a wire within operating on one or both blades. Gottstein's laryngeal forceps[6] had their place in the evolution of the instruments employed in the early eighties. To-day, however, we have gone back to the general shapes of Fauvel and Mackenzie, and I will present some of the modern modifications of the same, and especially the universal handle of Meyrowitz with laryngeal and sphenoid tips of Krauss and Cordes.

Various forms of epiglottis lifters have been devised for the better observation of the larynx during operative procedures. Among the best are Mount Bleyer's and Escat's.[7] These instruments are of the greatest assistance in cases in which an overhanging epiglottis is encountered. A downward and forward pressure at the base of the tongue in front of the epiglottis causes the latter to assume the perpendicular. These instruments are very useful in cautery work.

The preparation of the patient for operation is a simple one:

Cleanse the throat and larynx with an alkaline spray, and then spray into the larynx a 4 per cent. cocain muriate solution in small quantity. Touch the uvula, pillars and posterior pharyngeal wall with the same solution with a cotton applicator, and massage these parts with the applicator to accustom the throat to the feel of the instrument. Have the patient hold out the tongue with a napkin, or have an assistant, in case the epiglottis is in the way, use an Escat epiglottis lifter. The head of the patient should be steadied by a nurse and the instrument introduced, by daily practice if necessary, until all fear on the part of the patient is overcome. In operating it is well to educate the patient to use the vowel sound *A*, changing to *E* without moving the tongue. The *A* changing to *E* brings the cords on the highest plane possible, and gives the best view of them in their fullest extent. Then without dropping the cords and in the *E* emission, at the command, "Now," the patient should be taught to take a deep breath suddenly without making any sound or body movement, and with complete relaxation. At that instant the forceps are introduced and the growth is seized. This applies to subglottic growths and those on the border of the cords. Growths situated on the upper surface are removed during the *E* emission. It is surprising how skilful one may become in this procedure, so much so, that having habituated oneself to this method, direct laryngoscopy seems really more difficult.

The Pulpit on the Medical Profession.—As St. Luke's day fell on Sunday this year (October 18), the "praise of the physician as the servant of God" was the theme of many sermons. Dr. Prince of Chicago spoke from this text, saying that "the tendency in certain circles to-day to ignore the physician is a monstrosity." He compared the physician to the Panama Canal, the link uniting the ocean of man's need with the ocean of the power of God, defining the power of God in part as the "mastery of the spirit over the body." He said that the gain in the last fifteen years is this, namely, that "we have ceased to defend the absence of miracles in modern days. The 'faith' of many persons does not reach beyond the physician, but to ignore the physician and his science is to ignore the provisions of health, just as if we should ignore and do without the sunshine."

METHOD OF SUSPENSION (KILLIAN)

DEMONSTRATION OF THE LATEST FORM OF THE APPARATUS *

ROSS HALL SKILLERN, M.D.
PHILADELPHIA

CHOICE OF ANESTHESIA

After trying cocain, scopolamin and ether I and my associates unhesitatingly state that ether is by far the anesthetic of choice. Scopolamin has not been a success in our hands, although the technic as laid down by Killian, with even greater dosage, has been adhered to. Whether this lack of sufficient action has been due to the drug or to the difference in racial characteristics between the German and American, I am at loss to say. In our cases the patients were made only drowsy although 1/200 grain was twice and even three times administered in conjunction with morphin (1/64 grain), and in each instance it was necessary to resort to ether. The best form of administering the ether is the colonic method. The patient need not be apprised of the fact that he is being etherized and in this manner no apprehension on his part need exist.

DIFFICULTIES ENCOUNTERED

1. *Patients*—In order to procure a perfect view of the glottis it is almost necessary that the patient have a long, slender and supple neck. On this account this method of procedure is particularly adaptable to children as in practically every patient under the age of 12 we have been able to procure a good view of the anterior commissure. In short, thick-set individuals it is particularly difficult, and in older people with arthrosis it is absolutely contra-indicated. A good idea of its practicability on a given individual can be obtained by first endeavoring to examine him with the direct laryngoscope.

2. *Lights*—Either reflection from the indirect mirror, the headlight, or a light on the apparatus may be used. In our clinic the latter has been almost exclusively applied with almost complete satisfaction so far as illumination is concerned. The only fault at present is the tendency to slip off the mouth-piece and always at the most inopportune moment. If this mechanical fault were eliminated the device would be practically perfect.

3. *Operating-Room*—A special room is a great advantage although not absolutely imperative. The table on which the apparatus is fixed must be suitable for the purpose and adaptable to raising and lowering, as the operator is seated and must have his eyes on a level with the long axis of the patient's trachea. Arrangement of the theostat, instrument tables, etc., should always be approximately the same. A most important factor is darkening the room. In many of our modern general operating-rooms this is impossible.

INTRODUCTION OF INSTRUMENT

Care must be exercised in introducing the spatula, otherwise the following accidents may occur:

1. The spatula may not be deep enough, thus forcing the base of the tongue backward and obscuring the view to the glottis.

2. The spatula may not be in the median line of the tongue, causing a lateral bulging.

---

* Read before the Section on Laryngology, Otology and Rhinology at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

3. The spatula chosen may be too short so as to prevent the epiglottis holder from properly acting.

4. The clamp on teeth must be fixed and padded, otherwise the incisor teeth may be forced loose.

5. The spatula must not be forced into the mouth as the posterior pharyngeal wall may be lacerated.

6. While the patient is swinging, coughing must be guarded against as the hook may be thrown off the bar.

7. The patient in swinging position should have the shoulders resting on the table.

ADVANTAGES

1. A direct view of the larynx is continually present.
2. The operator is seated in a comfortable position.
3. The field is continuously illuminated.
4. A sufficient amount of working room for both hands is obtained.
5. The upper air-passages cannot be flooded with blood.
6. There is no danger of inspiration of blood or pieces of tissue.

PARTICULAR INDICATIONS FOR USE

1. Removal of intralaryngeal growth and hypertrophies.
2. Removal of foreign bodies in larynx and mouth of esophagus.
3. Curettage of larynx.
4. Diagnostic purposes.

2032 Chestnut Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. CURTIS, JACKSON AND SKILLERN

Dr. Robert Levy, Denver: The present generation, as distinguished from the older one that was expert in the indirect method, and that studied under the old masters, has something also to offer in the way of laryngologic skill. Among the younger men there are many whose early training, even within the past ten years, was sufficient to enable them to remove intralaryngeal growths by the indirect method. This in no way detracts from the importance of the direct method and the work of the early operators, but there is still much attention paid in the training of our specialists to the use of the mirror and manipulation by the indirect method; so that while the number of experts with the direct method become more numerous, nevertheless there are more men who are expert in the use of a mirror and the indirect use of the forceps than with the instruments used in endoscopy. So long as our teaching still enables us to perform operations with the mirror this method of removing growths and performing other manipulations within the larynx must of necessity continue. I would not in any way detract from the advantages of endoscopy. Many improvements have been made in the instruments since 1880 and Curtis has shown some. The double curet particularly is a great improvement. Another instrument of great value is the Schlinamann forceps, an instrument which has at its extremity a small curve, so that the instrument may be placed in any position. It is capable of great nicety of manipulation. The overhanging epiglottis may be controlled by the Escat depressor but more satisfactorily in some instances by putting a ligature through the epiglottis. Then it is absolutely under control. This is particularly useful in operating under general anesthesia. Another method of operating within the larynx and one especially useful in large tumors is by means of the snare used in the following manner. Through the loop of wire one passes first a pair of laryngeal forceps the handle of which may be locked. The tumor is firmly held by the forceps and the snare-loop drawn completely over the growth. Gentle traction by an assistant draws the tumor by means of the forceps well into the loop at the same time that the operator passes the loop around the tumor. In this way the complete removal of a sessile growth is readily accomplished. One method Dr. Skillern did not speak of, though I am sure he has it in his paper, is that of bringing the anterior commissure into view by making counter pressure over the thyroid cartilage; another thing is that suspension is especially valuable in the case of children. There is no other method by which the child can be so easily operated on as by this one. With reference to anesthesia, Dr. Skillern said he used ether by preference. I question whether he would administer ether in every case to an adult on whom he desired to perform some simple procedure under suspension.

Dr. Harris P. Mosher, Boston: Naturally, when this procedure came in, rather extravagant claims were made for it. It has been in use now for a number of years and I think the consensus of opinion is that we need to modify those claims but little and that is saying a great deal for a new procedure. It is one of our great advances in the work on the larynx and upper end of the esophagus. Dr. Murphy said to me when this first came out, "What we need is simplification of the apparatus." It is rather complicated. If we can simplify the instrument or procedure in any way, it will be well worth while. I am familiar with the open speculum and tried to do what I could to modify that speculum and I think I can claim that now in 90 per cent. of cases it will work for this method of inspecting the larynx. When the procedure was introduced it was to be used under cocain. I am glad it has been changed to a procedure under general anesthesia, because I work practically always with general anesthesia. The satisfaction of seeing the cords right in front of one and of watching the rhythmic movements is beyond expression.

Dr. Lynch of New Orleans, who recently read a paper at the meeting of the Laryngological, Otological and Rhinological Society, has markedly extended the procedure and has devised instruments for dissecting out growths, papillomas, etc., in the larynx, and I feel that that is a great advance in the use of the suspension method. As for the removal of tonsils in this way, every one who speaks of it says that the tonsils can easily be removed by the suspension method.

Dr. Sidney Yankauer, New York: I have used the suspension apparatus ever since it was first brought out by Killian and I endorse all that Dr. Skillern has said about the advantages of the use of this method for intralaryngeal work. I do not quite agree with Dr. Skillern about the particular instrument used. I had the original instrument as it was first brought out by Killian, and also this later model. The later model is much more complicated than the original and I find that with the original instrument and spatula I can bring the anterior commissure into view in practically every case without making counter pressure, and in every case with the aid of counter pressure. With the newer apparatus I haven't been so successful in this. The epiglottis lifter seems to be rather in the way. The tooth plate on the newer apparatus is larger and longer and gets in the line of vision. Killian uses the method very much in the removal of tuberculous lesions, which are generally in the anterior commissure. About a year ago I operated in a case of carcinoma of the epiglottis and the manner of the removal of the growth was so entirely different from anything that could have been previously done and the success was so much greater than by any other method that there was no question about the great advantage of this method. At the recent meeting of the Laryngological, Otological and Rhinological Society the removal of foreign bodies by the introduction of the bronchoscope with the suspension apparatus was spoken of. Some time ago I had a case of a tumor on the posterior wall of the trachea and tried this method. While I was able to remove the growth I was not quite satisfied with the aspect of the posterior wall and tried to introduce the tube, but the larynx first comes forward and then makes a bend downward and I could not get behind that curve with the tube. Recently a patient was seen who said he had swallowed a fish bone. It was just below the cricoid cartilage. It was removed under local anesthesia by the suspension method. I can endorse what Dr. Skillern says about the introduction of the open tube into the esophagus being easier with the suspension apparatus, as it partly opens the esophagus, but after the entrance of the tube all advantage of the suspension method is lost and it is in the way. In the case in question I failed to see the foreign body and could only see the anterior wall and part of the lumen; I could not see the posterior wall. Therefore, the only advantage in passing the esophagoscope with the suspension method is the ease of introduction, but by this the mobility of the tube is sacrificed. If the extraction is difficult or the foreign body is against the posterior wall, the suspension apparatus interferes with movement of the tube and that is a very important objection.

Dr. Thomas E. Carmody, Denver: I am glad to hear Dr. Yankauer speak of operating on the epiglottis. I have used this instrument about fifteen months and have examined some cases of tuberculosis in which we wished to remove the epiglottis, but being more familiar with the indirect method I used that. The experience of Dr. Yankauer as to impaired movement of the esophagoscope after introduction with the suspension apparatus has been mine also. There are two modifications, one of Lockard's, which has an eyelet so that the horizontal portion can be separated; the other is a vulcanite rubber pad on the tooth plate. This must of necessity be of the soft or velum rubber so as to conform to the shape of teeth or anterior part of the palate.

Dr. E. J. Bernstein, Kalamazoo, Mich.: We are indebted to Dr. Curtis for his views regarding singers' nodes and his method of treating them. Just how much does Dr. Jackson think there is in Dr. MacKenzie's criticism of taking off a slice of growth for diagnosis? Most of us feel there is great danger in excising a portion of any growth for diagnostic purposes, as it may likely cause absorption by the lymphatics and bring about metastases elsewhere. I know such is the view in major surgery. In removing the breast for malignant growths, the surgeons first attach and tie off the arteries, veins and glands remote from the breast and cut wide and away from all involved structures.

Dr. H. W. Ridpath, Indianapolis: One can readily see that, in the removal of tonsils by the suspension method, the stretching open of the mouth in this position will bring considerable tension on the anterior and posterior pillars. That forces a portion of the tonsil into the median line and it will be found that the superior portion of the tonsil is drawn back into the cavity; therefore, in enucleating tonsils by this method one must be careful to get the superior lobe out, as otherwise it will be overlooked. One other point. We have in our clinic several patients in whom the tonsils had been partially removed or massacred by some other operator, and who were brought in to the hospital in a serious condition as to bleeding. On two occasions it was impossible for us to stop the bleeding by ordinary means, due to the amount of hemorrhage. The patient was put in the position in which blood would go down into the postnasal space and one could get a clear field and ligate without difficulty. One of our patients I am sure would have bled to death if we had not as a last resort used this method.

Dr. Otto T. Freer, Chicago: The direct method of entering the larynx has merely added to our powers, it does not supplant the older way of operating with the mirror; and to be an expert the operator must be trained in both methods. The use of the spatula tubes employed for direct laryngoscopy puts a strain on the muscles attached to the hyoid bone and on the thyrohyoid and hyo-epiglottic ligaments. This strain is borne by some patients with but little discomfort, but others suffer a good deal when much force is needed to get a direct view. However brilliantly done, direct laryngoscopy is a forcible entry into the larynx, while the indirect method has the advantage of entering along the natural curves. It is therefore incomparably the more elegant and gentle way and merely because he has not learned it, the operator has no excuse to turn to the rougher direct way in order to remove a papilloma from the cords or a foreign body from the larynx. I reserve the direct method for cases in which I cannot operate with the mirror as in the case of children. In younger children, because of the smallness of their laryngeal lumina and their ready closure by swelling, it is best to precede an intralaryngeal operation, as for laryngeal papilloma, for instance, by a tracheotomy. I have always used this precaution, and twice, once in an operation on a child for laryngeal papilloma and again in a case of a bone in the larynx, although all gentleness and speed were used, the larynx closed by swelling for a day or two and I was glad that I had my tracheal tube in place. I have heard of others, good operators, who have had to do a hurried tracheotomy after an intralaryngeal operation on a child and in one case the operator was too late. In holding the cutting forceps for operating with the mirror it is customary for many to enter the rings of the usual scissors-handle by placing the thumb in the uppermost ring. This hinders wrist flexion and so prevents the operator from reaching the anterior commissure with the beak of the forceps. When the thumb is placed in the lower ring and the index finger in the upper, flexion becomes easy and all parts of the larynx can be reached without effort.

Dr. George F. Cott, Buffalo: One point which has not been brought out is the matter of tolerance of the larynx in children; how long will it tolerate manipulation? I had a sad experience in this connection: a child had a key in the esophagus for a week. I introduced the esophagoscope but could not find the foreign body, although roentgenoscopy showed where it was. The swelling was so great I could not see it. I worked a half hour and then decided to do a lateral esophagotomy, which I did. It took but a short time and the key was removed, but that night the child suddenly died without any apparent cause. I found out later that another physician had worked on the child for an hour or more by the indirect method before I saw it. Had I known that, I would not have subjected it to such a continued shock.

Dr. A. B. Thrasher, Cincinnati: Dr. Curtis has partially repaid a very old debt which we laryngologists have so long owed to a singing-teacher, E. Garcia, for the discovery of the laryngoscope. Now a laryngologist teaches the proper singing method for the prevention and removal of singers' nodes. I turn these cases over to a singing-teacher with the instructions which Dr. Curtis has given us.

Dr. W. B. Chamberlin, Cleveland: Although my early training and instruction was in the indirect method, I have used the direct method almost from its beginning. I am in favor, however, of the indirect method in suitable cases. It is certainly a much less formidable operation than the direct method. I fancy that if any one of us were offered his choice of the methods on himself, he would unquestionably choose the indirect, granting, of course, that it were applicable to the particular case. Not long ago I was able to remove very easily a pedunculated tumor from beneath the cords at the anterior commissure in this way. There is an opinion among men who have been trained in the direct method that the indirect method is difficult. That is not so. It is no more difficult than the methods which the dentist uses every day in his operations on the teeth. Take a wide-mouthed morphin bottle, cover it with dark paper, and on the bottom sketch a larynx, then place a shot or pin in any position and one can practice the indirect method to one's heart's content.

Dr. Burt R. Shurly, Detroit: Those of us who have used the indirect method for many years have a certain amount of sentiment concerning this method, and we sincerely trust that it never will become a lost art. There are a great many things one can do by this method first, and then if not successful one can use the direct method if necessary.

Dr. C. G. Dwight, Madison, Wis.: The otolaryngologist who lives in a large city knows very little of the disadvantages encountered when the general surgeon has first had the case. Most of my work is in the removal of foreign bodies. I had in one case a Catholic sister who had lodged in her throat a black-headed pin such as they use to fasten their bonnets. The patient had been in the hands of a general surgeon three hours before I was called to see her. The pin was lodged straight across and imbedded. Of five different instruments none were powerful enought to detach it because it was so firmly imbedded. I broke two instruments in the attempt. This led me to devise an instrument which is useful for grasping pins of this type. The delicate instruments we have for grasping growths, etc., are very perfect, but we need something stronger to remove these firmly-imbedded things.

Dr. Holbrook Curtis, New York: I am glad to see that there are so many advocates of the old method. I agree with Dr. Freer that we should be expert in both. No laryngologist can afford to neglect the opportunities in which he can use the indirect method. With regard to practicing the indirect method, I have taken an old pin-cushion and put it at the bottom of a three-inch iron tube and then practiced picking the pins out one by one, using a laryngoscope and forceps.

Dr. Chevalier Jackson, Pittsburgh: In reply to Dr. Bernstein's question with regard to the removal of a specimen in malignant cases, as Sir Felix Semon pointed out years ago, it is unwise to remove a specimen in any case that, clinically, seems to be malignant unless the patient has consented to immediate operation in the event that the specimen proves malignant. The question should be submitted to the patient beforehand. If he declines external operation, which is the only route in malignancy, then no specimen should be taken. If consent has been obtained, preparation must be made to operate immediately, as soon as we get the report on the frozen section, which we can get now on the same day that the specimen is taken. There is little risk of metastases resulting if operation immediately follows.

Dr. Ross H. Skillern, Philadelphia: Dr. Levy spoke of this method not being used in the simple procedures in the larynx, such as making examinations and removing papillomas, under ether. We have tried it without ether and have succeeded. So far as Dr. Mosher is concerned, he is too modest to state that he perfected an instrument of his own and had I seen it first the Killian instrument would not have been in our armamentarium. I had the pleasure of seeing his work, and later the work in the Chariteé in Berlin, the home of this method, and had I to have the method used on me I should prefer to go to Boston. As to the removal of foreign bodies by this method, we have in the last month removed a number of such bodies and it progressed very nicely, except the last case, a penny in the esophagus. We saw it very beautifully and demonstrated it to several physicians in the room with a great deal of pride, but the pride went just before a fall because when we went after it it went down and down and finally passed into the stomach. Dr. Ridpath spoke of the enucleation of tonsils by this method. In that respect one thing is notable: the remarkably small amount of hemorrhage when this method is used. It is due to pressure on the tongue and some of the vessels that supply the tonsil. As soon as we take the tonsil out the blood seems to start up but is soon controlled. Dr. Freer spoke of the matter of soreness of the throat after the employment of this method. In 100 or 150 cases the children did not complain of any particular soreness. I have asked them frequently. Some of the adults complained of a certain amount of stiffness in the neck. I am not advocating any particular method in every case. We must select the method that is suitable for the case in hand.

The Medical Profession and the Eradication of Disease.—People say there must be a "nigger in the woodpile" somewhere, that the medical profession should strive to reduce illness, for it is thereby they make their living. I will acknowledge the doctor is a queer beast, but his mission in life is not to accumulate any great wealth, but to eradicate disease, and that alone will make him happy. I deny most emphatically that money is the strongest motive that moves the mass of mankind. I will admit that anything that requires money is not easily accomplished, but a good lawyer, if you will go to him with your case, will advise you in the majority of instances not to litigate, and a good preacher will try to save your soul before it gets past saving; and the good doctor rejoices much when he can keep you well.—Victor C. Vaughan, *Jour. Indiana State Med. Assn.*

HEALTH SERVICES IN AMERICAN COLLEGES AND UNIVERSITIES

WARREN E. FORSYTHE, M.D.
Staff Physician on the University of Michigan Health Service
ANN ARBOR, MICH.

The wide-spread interest in the economy of health conservation has placed this consideration of medicine on a sound basis. The means to this end are being socialized because it is of public concern. It is significant that this broad consideration of health and disease has crystallized early around our educational institutions.

In our colleges this work has assumed the form of variously organized health services. These services provide for care of individual sick students, but recognize instruction, inspection, and the preservation of health as equally important work.

GENERAL METHODS

All university health services have certain uniformity of methods since they have similar aims in view. Differences apply to peculiar local conditions and policies.

A general policy is to provide easily accessible medical attention to the student, with instruction and preventive service. Medical attention is also provided for the faculty and officers in a few services.

The staff usually consists of a university physician, health officer, or medical adviser, as he is variously designated, with assistants as required, often including a woman physician.

A committee of the faculty often serves with the staff as directors.

At most places convenient quarters are provided where examinations and office treatments are supplied. A number of services provide for bed patients in student hospitals spoken of as infirmaries. A medical department in a school is a great help to the student service.

The expense of this work is usually provided for by a general student fee. The connection of staff members with the teaching faculty provides for part of the salaries, from the institution.

ENDOWED AND PRIVATE INSTITUTIONS

The older health services at the endowed schools have as a rule been slower in development and more conservative in their policies than the leaders among state universities. As a class they have better infirmary facilities, but are less active in dispensary and inspection work.

Princeton

Since 1893 an infirmary has been maintained at this institution for the exclusive care of students in illness. There have been recent plans for a new building in the work. The infirmary is endowed and has about thirty beds. Hours are kept for office consultations, which average about fifteen daily. There are 1,500 students, who pay an annual fee of $7 each, for which they receive consultation and treatment with limited time in the infirmary where at request they may have local physician of choice and special nursing at their own expense.

There have been about four hundred bed patients annually. The examination of freshmen at the gymnasium is especially well done by Dr. Joseph Rycroft, who is much interested in this work. General inspection has been provided for by the local health officer, whose salary has been paid in part by the university. Dr. Conochan is in charge of the clinical work.

Harvard

The service was established here in 1894. It is now in charge of Dr. H. M. Bailey, who has no assistants and devotes most of his time to the work. Students at Cambridge pay $4 a year as general tax, which provides for office consultations, treatment and limited care in the infirmary. Dispensary consultations average about twelve daily, including calls at the rooms as requested. The dispensary is located in one of the dormitory buildings on the campus.

The infirmary is a splendid new building, well endowed and thoroughly modern in every respect. It has sixty-five beds, about one half of which can be used for isolation purposes. Patients are given ordinary nursing except as they provide for themselves. They usually have outside physicians while in the infirmary, although the university physician cares for those unable to pay. There is an average of about five hundred infirmary patients annually.

Examination of entrants is done by the physical director, and is limited to a consideration of their physical exercise and athletic work. No lectures in hygiene are required.

Cornell

Since 1911 an organized service has been in operation at Ithaca. A general fee of $6 is received from about 4,600 students. Three physicians, including one woman, see an average of sixty patients daily for consultation and care of minor troubles. Major cases requiring continued treatment are referred to local physicians. Advisory calls are made at the rooms.

An infirmary is maintained with sixty beds, where two weeks' ordinary care is given. Patients pay physician of choice for all services, medicines, and supplies. There were 1,041 bed patients during the last year. Examination of freshmen is compulsory and lectures on hygiene are optional. The service has complete medical care and examination of athletes. Dr. S. Munford is in charge.

Columbia

A service has been established here during the past year. Dr. W. H. McCastline keeps hours twice daily, caring for about thirty students. A well-equipped dispensary is maintained in one of the campus buildings. The service is rapidly extending although there has been no definite provision whereby the service can give infirmary privileges to bed patients. No fee has been charged of the student as the dispensary has been established and maintained by the university. Examination of entrants is limited to that in the gymnasium, and no general lectures in hygiene are required.

Yale

The conservatism in this work is especially felt by those most interested in the health of the students at Yale. A suitable endowed infirmary is maintained in charge of a nurse matron. Students pay $1.50 a day for ordinary care and employ their own physician and special nursing. There is no organized student health service, and Dr. W. G. Anderson as gymnasium director has been able to do but little in the way of medical examination and instruction in hygiene. That an organized service could do a splendid work at Yale is the conclusion from my recent visit there.

Stanford

The work here has no organization as a definite service. The provision for the student health is supervised in general by a committee of the faculty. This committee is responsible to the president for the public health of the campus. They inspect rooming-houses enforce vaccination, and do some detailed work through the medical advisers who are directors of the gymnasia.

The medical advisers, one woman and one man, act in an advisory capacity in connection with their work in the gymnasia. They do no treatment, but examine entrants in relation to their gymnasium work. Bed patients are provided for by an organization of students known as a hospital guild. This is supervised by a faculty committee, and membership is compulsory for each student at $4 per year. This entitles the student to ordinary hospital care in a local hospital, except for contagious cases, which are provided for otherwise by the guild. Medical care, private rooms and special nurses are not furnished the patient.

Chicago

During 1911 a committee of the faculty of the University of Chicago was appointed to investigate student health problems. A thorough study was made of their own situation as well as systems then in operation at other schools.

Their report emphasized the obligation of a university in the provision for good health among its students. The sanitary condition of their university was pointed out; the general policies and methods of other institutions were shown. The recommendations of this committee were to the effect that there was need for an organized service to coordinate the activities of the various departments of the university whose work touched on sanitation. They recommended the maintenance of an infirmary for students; that general instruction by lectures be developed by the health officer for new students and that such entrants be given a medical examination on matriculation. They asked that consultation hours be maintained for sick students and that vaccination be enforced.

A recent report is to the effect that the university has not undertaken the care for sick students since October, 1912, up to which time there had been a university physician. A committee of the faculty supervises sanitation and the gymnasium directors do some medical work among the students incidentally. Freshmen are examined at the gymnasia and are required to attend lectures on hygiene during the first quarter. The policy seems to be not to assume responsibility in caring for sick students.

Williams

A twenty-four-bed infirmary is maintained for students, faculty, and their families at a rate of $1.50 per day for the patient.

The staff is composed of three local physicians, one or whom, Dr. F. H. Howard, delivers compulsory lectures on hygiene and examines entrants. Other physicians care for infirmary patients at request of parents. There is no general fee and no dispensary work is done.

Massachusetts Institute of Technology

At this school the 1,700 students pay no fee. They may consult a college physician during certain hours. The medical adviser delivers lectures to first year students.

Pennsylvania

The University of Pennsylvania has no organized health service. The need of it there is felt by those most in touch with student health. The ample facilities at the university hospital on the campus have supplied this want with certain satisfaction. The exclusive ward for students makes a suitable arrangement for cases requiring bed care. The patient pays a nominal fee for ordinary care. The medical attention is supplied by the hospital staff.

Haverford College

For a small school the service is especially commendable. The students contributed a sum of money and a beautiful infirmary building, well equipped, has been established by added endowment. Dr. J. A. Babbit is teacher of biology, director of the gymnasium, and college physician. The cooperation of these departments is a special feature of this excellent service.

Culver Military Academy

As an instance of the provision made in boys' preparatory schools, Culver may be cited. An organized service has been working there since 1908. There are about four hundred and fifty students during the regular winter term. The medical staff consists of one physician and two nurses devoting full time. The average of dispensary calls is about twenty daily. Room visits are made as needed.

A seventeen-room infirmary is maintained. It is in charge of the academy physician, who asks outside consultation as required. Two hundred and fifty bed patients were treated during the last session. Frequent examination of all students with weekly lectures in general hygiene are required. General supervision and remedial gymnasium work are emphasized features. Dr. C. E. Reed is physician in charge.

Vassar

For about twenty years this school has made provision for student health. About one thousand students are cared for. Three women physicians, headed by Dr. Thelberg, are employed in the service, and they do some other instruction work in the college.

A good dispensary is maintained and detailed treatment is given. The thirty-room infirmary where bed patients pay $1.50 a day, is well equipped. Careful examinations are required on entrance and attendance on lectures is compulsory.

Wellesley

This school has a plan very much as that described for Vassar. Each of the thirteen hundred students pays a $5 annual fee. For this they receive dispensary privileges, supervision, and two weeks' care in a well-equipped infirmary. Dr. Katherine Raymond and two nurses are employed. Local physicians are called at request of the patient. The inspection of entrants is especially complete.

Smith

Until the last year the service was much as described for Vassar and Wellesley. Since that time the policy has been changed. Hours for advisory consultation are maintained and cases requiring treatment are referred to local physicians. The local physicians aid by making careful reports to the college physician, Dr. Florence Gilman, also director of the gymnasium, who has large authority in handling medical affairs at the school.

The infirmary is inadequate and inferior, although a suitable rest home is maintained in addition. The generous inspection of the school and the examination of entrants is well maintained. Lectures are provided for instruction in hygiene. There are about fifteen hundred students.

STATE UNIVERSITIES

California

As typical of the progressive element in western institutions the university of California has probably developed the best service. It has been organized since 1906. Dr. G. F. Reinhardt, professor of hygiene in the university, heads the staff and does the surgery in addition to the administrative work. Two men care for the daily clinics and house patients. One man for eye, ear, nose, and throat trouble is kept very busy during part of each day. Another man does epidemiologic work, and three women do the clinic and house work for the women students. One of the women does a large amount of orthopedic work and one of them has charge of anesthesia and the laboratories. Each of the eight physicians works with the service about four hours daily. Some of them are connected with the medical teaching staff of the university.

There are over five thousand students who pay $6 each annually for medical service. Operations and special nursing are not covered by this sum. The average daily dispensary patients number about one hundred. Calls are never made in the rooms, as bed patients are sent to the infirmary, which is exclusively for students and has forty beds. Five hundred and eighty bed patients were treated during the last year. Local physicians are called as consultants only.

"Applicants must appear before the university medical examiners and pass a satisfactory examination to the end that the health of the university community may be safeguarded." During two years seven were refused admittance to the university by the service. Of these three died later of tuberculosis and one is in an institution for the insane. Weekly two-hour lectures on hygiene are required of freshmen during the first term.

In a report Dr. Reinhardt points out that through the service the students receive valuable education from experience with economical and efficient organized medical aid; that similar statistics and observations can be made in no other way; and that such service instils democracy. The published reports of this service with reference to the diseases of young adults are elaborate and instructive.

Michigan

Out of general demand from the campus the organization of a service was undertaken in October, 1913. It was organized to undertake both preventive work and instruction, and the care of students when ill.

Administrative officers and deans serve with the staff as directors of the service. Dr. H. H. Cummings heads a staff of four full-time physicians, including Dr. Elsie Pratt, whose duty is with the women. A pharmacist dispenses drugs without added expense to the students.

A building on the campus is equipped for examinations and office treatments. These have averaged about sixty daily throughout the college year. The university hospital provides excellent consultation and care at small expense to bed patients able to pay.

Over five thousand students paid a compulsory fee of $2 each. For sick call at the room the patient pays to the service fund $1 for day and $2 for night call. Summer students pay a general fee of 50 cents.

Next year the college year fee is to be $4. This will enable the service to send any student into hospital care for sixty days' limit without added expense to the patient. The contemplated examination of entrants with early and vigorous isolation of infectious cases should do much for the protection of the student group. Compulsory lectures on hygiene for the freshmen would further assist. It is planned to enrol members of the different house groups as health service representatives. These students will be instructed so that they may be of value in preserving the good health of their several houses.

The health of students at Michigan is generally good; in the last few years, however, there has been an apparent epidemic of acute pharyngitis.

There has been no expressed opposition to the service. Student sentiment is eminently satisfactory. Students have been surprised that in the past they did without such a service, where now in need they come for advice and treatment.

Iowa State

Since 1886, a service has been at Ames. Dr. C. G. Tilden is the only staff physician.

Twenty-eight hundred students pay an annual fee of $4 each. Daily calls average one hundred. Calls at rooms cost extra. Lectures and physical examinations are given in connection with gymnasium work only.

The infirmary has thirty beds and cared for 370 patients last year. Infirmary patients pay $3 weekly for three weeks and $7 thereafter. Local physicians treat infirmary patients at the discretion of the college physician.

Wisconsin

Since 1910 an unusually good service has been operated at Madison. Without special fees from the students the university has taken hold of many problems concerning student health and general medical instruction. Broad economy rather than medical philanthropy is given as a policy in their service.

The staff has six full-time physicians intimately related to the medical faculty. The duties of these men embrace teaching, research, and attention to the health of the individual student.

An ample infirmary has not been developed, although two hundred and fifty bed patients were provided for in a general hospital. This was done at nominal cost to those able to pay. In the dispensary, detailed treatment was given to about one hundred and twenty students daily during the last school year. Calls at sickrooms have averaged about ten daily.

The medical examination of entrants is considered important, but lectures on hygiene are not required. The service supervises sanitation throughout the university as for example, instruction is given to janitors and other university employees.

As emphasized features, Dr. J. S. Evans may be quoted. "There is close relationship between this department and the administrative officers in an attempt to correct errors in our educational practices. The compulsory observation of each student given special privileges because of medical defects. The attempt to prove that the prevention and treatment of disease must go hand in hand in the development of public medicine."

As in other institutions, the local physicians have had trouble in adjusting themselves to the advances of this service. The situation is fast coming to be recognized, however, as the natural course of medicine in its relation to public welfare.

Texas

The University of Texas has had a service since 1910. Twenty-two hundred students pay a fee of $5 a year for this service. A woman physician during two hours daily cares for girls. Dr. Joe Gilbert, in charge of the service, cares for male students in the same way. The number of office patients averages fifteen to forty daily, detailed treatment being given. Calls at the rooms are made without charge for the first three visits.

Hospital arrangement is made with a local hospital for the care of students. The hospital receives $15 per week for each patient and gives in return ordinary care. The patient receives five hospital visits from the university physician without cost. When another physician is called the patient pays for his services, but the hospital care is provided the same. Bed patients average from five to ten daily. Provision is made for compulsory examination of freshmen on entrance and for lectures on hygiene, which must be attended.

Washington

During 1910 a sick benefit service was organized as a result of student agitation. It applies only to those students who come from out of the city and are not under the jurisdiction of some home in Seattle. A fee of $1 is collected by the university for the privileges given. The director of the service is a physician, who cooperates with the faculty committee on hygiene and sanitation. Sick students are first seen by the director without expense for the first visit. If continued medical attention is required, a local physician is called by choice of the patient or in rotation by the director.

Patients requiring hospital attention are sent to local hospital without additional expense to the patient. All entrants must have a medical examination. They also are required to take a course in hygiene consisting of one hour per week throughout the year. It is pointed out that this service does not interfere with the family physician, and that it reduces the student's expense because of the free first call which is all that is required in the majority of cases. It is expected that the fee will be increased soon to $1.50.

Missouri

A service was organized in Columbia, Mo., in 1910. Dr. Moss devotes his entire time to the work and the University Hospital is available. Twenty-five beds were used last year without additional expense to four hundred bed patients. Local physicians may care for hospital cases at the choice of the patient. Office calls average about twenty daily.

There are about three thousand five hundred students and each pays a fee to the service. The examination of entrants and lectures on hygiene are required.

CONCLUSIONS

For the institution which recognizes an obligation in the care of student health, and wishes to handle it certain things are advisable.

1. A definite organization should be able to use and direct effort in any department of university work, to the purpose of the service. The work should be headed by an interested physician who devotes, preferably,

whole time. He should be given large authority in carrying out the policies of the service and additional staff as needed. Having a supervisory board of the faculty is helpful.

2. The needed equipment depends on that available in other departments of the university. If the policy of detailed treatment is chosen, which seems the most practical, a definite headquarters must be provided with ample room sufficiently convenient that students may call without loss of time. Good office facilities and a laboratory are needed for efficient work.

Provision for bed patients should especially include care for contagious cases. This should be so provided that there need be no financial hesitation about ordering any suspicious case into isolation.

3. The service expense should be borne largely by the student through general tax. Money for this purpose is economically spent by the institution. The use of staff members on the teaching faculty provides for part of their salaries.

4. The work of instruction, inspection, and supervision is to be emphasized. The effect of instruction in matters of hygiene and sanitation has an unlimited scope as directed to future teachers and leaders. If this provision for the care of health impresses students favorably, there should be demand for similar service outside the university. The relation of such services to the medical profession should be early established.

The health of a school will depend in part on the health of those admitted. It is certain that schools should be protected from a number of applicants each year, and that a good medical examination would avoid some failures in a college career.

THE THERAPEUTIC EFFECT OF IODIN *

JAMES W. JOBLING, M.D.
AND
WILLIAM PETERSEN, M.D.
NASHVILLE, TENN.

Iodin and the iodids, either in inorganic form or as organic compounds, have been successfully used for many years in the therapy of various disease conditions, without definite knowledge as to their mode of action in the body.

The beneficial results obtained, more especially the effects in causing absorption of necrotic material, such as is found in gummata, have been variously ascribed to the influence on the general metabolism of the body; to the lowering of blood-pressure; to changes in the viscosity of the blood; to a lymphocytosis; to increased lymphatic activity and to the oxidizing properties of free iodin. As is so frequently the case, the very multiplicity of these views indicates that probably none is satisfactory; indeed, practically all the theories advanced have been seriously questioned.

Much work has been done on the absorption, distribution and excretion of iodin. (Winternitz, Wells, Loeb, McLean.) The older view that iodin combines with the proteins of the body has been disproved by McLean, who found that in experimental animals the lipoid fraction of the tissue contained 32 per cent. and the water soluble fraction 67 per cent. of the iodin absorbed. The extracted protein contained no iodin.

In a series of papers recently published we have demonstrated that the lipoids containing unsaturated carbon atoms are antitryptic when in colloidal solution; that tubercle bacilli and tuberculous caseous material contain such lipoids, the resistance of caseous material to solution and absorption being due to the presence of these compounds, the inhibitory effect of which is overcome when the caseous material is extracted with lipoid solvents, or when the unsaturated bonds are oxidized or satisfied with iodin.

We have furthermore shown that the antitryptic activity of the serum is due to similar lipoids which can be extracted with lipoid solvents (chloroform, ether, etc.). We have observed that iodin and the iodids when incubated with serum, markedly lowered the antiferment property. Serum from which the antiferment has been extracted becomes toxic because of autolysis (serotoxin), a similar process (absorption of the antiferment by agar, kaolin, bacteria, etc.) being the basis of the toxicity of the so-called anaphylatoxin.

These studies suggested the possibility that the action of iodin in the body may be due to a combination with the fatty acid, the saturation of the unsaturated valences causing a corresponding neutralization of the antiferment activity of these lipoids. This lowering of the antiferment index of the blood and tissues in general would permit the removal of necrotic tissue by autolysis. In view of the work of McLean showing that a large amount of the iodin is actually combined with lipoids after absorption, such an explanation might seem rational.

Drs. Fordyce, McMurty and Sharpe of the Vanderbilt Dermatological Clinic, Columbia University, have kindly placed at our disposal a series of cases in which we were able to determine the antiferment index of the blood at various times, both before and during the course of iodid therapy. In these thirteen cases, eleven of which were specific, we have observed a progressive lowering of the antiferment index of the serum, the effect being greatest when the limit of tolerance was reached—from 100 to 150 drops per day of a saturated solution of potassium iodid. The number of cases studied is not large, but the results were sufficiently uniform to show that the iodids so administered to human beings cause a considerable reduction in the antiferment activity of the blood, the net result being of course an increase in the proteolytic activity of the blood and tissues.

In those patients in whom toxic symptoms were noted (gastric disturbance, rash, etc.) the antiferment index, which had been lowered, was increased to the original strength, this being similar to the effect observed following many other intoxications—anaphylaxis, serotoxin, burns, protein poisoning; such a toxic rise being most probably due to a mobilization of lipoids from cells, will, of course, defeat the object for which the iodids are given.

TUBERCULOSIS

The impression is quite general among clinicians that iodids are harmful in tuberculosis, as they promote the spread of the infection by causing a softening of the tubercles and also interfere with connective tissue formation. Whether or not caseous tissues take up iodin from the circulation other than in a

---

* From the Department of Pathology, Vanderbilt Medical School, Nashville, Tenn.

* Complete protocols and references to the literature will appear in a more detailed report in *The Archives of Internal Medicine.*

purely physical manner, is an open question. (Loeb, Wells, Lewis). Boudreau believes that iodin is a specific agent in the treatment of tuberculosis and reports favorable results.

In our work on the antiferments contained in tubercle bacilli and in tuberculous caseous material, we found that the enzyme-inhibiting action was due to the unsaturated fatty acid radicals of the lipoids. At first we believed that this action was due entirely to the soaps of the unsaturated fatty acids, but subsequent work showed that a large portion of the enzyme-inhibiting agents could be removed by extracting with chloroform. The substances contained in the chloroform extracts are not active as anti-enzymes when suspended in salt solution, as they are insoluble; but the sodium soaps prepared from these acids are active, and we found that their activity was in proportion to the degree of their unsaturation, but that this action was lost if the acids were first saturated with iodin. These experiments were repeated with the chloroform extracts of tuberculous caseous material and with unextracted caseous material, with the result that the soaps prepared from the chloroform extracts became inactive, and the caseous matter which, previous to treatment with iodin, had not been acted on by trypsin, was now readily attacked. The loss of anti-enzyme action cannot be attributed to any activating influence on trypsin, as iodin inhibits the action of this ferment.

Thus we have definite evidence of the action of the iodids on tuberculous tissue, and the explanation of the well known clinical observation that iodids cause tubercle bacilli to appear in the sputum of patients with pulmonary tuberculosis, though they were previously absent. When iodids are taken into the tissues a portion of the iodin is liberated and combines with the unsaturated carbon atoms of the fatty acids. As soon as this occurs in necrotic tissue to a degree sufficient to lower or remove the antiferment action, autolysis ensues, as in most instances ferments are present. That the inorganic iodids diffuse readily throughout caseous matter and are thus in a position to furnish the iodin, has been shown by Loeb and Michaud, and Wells and Hedenberg.

SYPHILIS

Clinical experience teaches us that in the tertiary stage of syphilis iodin is almost a specific in bringing about the amelioration of symptoms, and the disappearance of lesions, and yet little is known concerning the means by which these results are obtained.

Authorities on this subject are unanimous in the belief that iodids are not curative in the sense that they prevent the return of the lesions; this can be accomplished only when the iodids are combined with some other form of treatment. Tomasczewski found that the administration of iodin does not prevent the development of experimental syphilis in monkeys and rabbits; neither has it a curative action; but iodized animals recovered quickly when given mercury. That iodin does penetrate into syphilitic tissues has been shown by O. Loeb.

As experimental work and clinical observations have demonstrated that the iodids do not destroy the infecting organism, we must assume that the results obtained are due to the power the iodids possess of causing resolution of the lesions present. That this actually occurs will be attested to by every clinician of experience.

Owing to its scarcity we have not been able to examine material from gummata, and so we are unable to state positively that the anti-enzymes present are similar to those found in tuberculous caseous matter, but it is probable that the same agents are active here as in those anemic infarcts in which autolysis does not occur. If this assumption is correct, it is not difficult to explain why large gummata rapidly disappear when the patient is brought under the influence of iodids. It is due to the fact that the unsaturated fatty acid radicals which inhibit autolysis, have become saturated with iodin. As soon as this occurs, the ferments which are present, or which may be brought in, become active, autolysis takes place, and the necrotic tissue is absorbed. Here, also, the local action of the ferments is made less difficult by the reduction of the anti-enzyme in the circulating blood. It must be borne in mind that the iodids are not as effective in the earlier stages of syphilis when necrosis of tissue is not so evident.

If the above interpretation of the action of iodin is correct, it gives the clinician a rational idea of what he is accomplishing when he gives iodids to a patient in the tertiary stage of syphilis. According to this view, iodin neutralizes the action of the agents which prevent resolution and absorption of the diseased or necrotic tissue, and at the same time lays bare to the action of the real germicidal agent the infecting organism which previously had been protected by the necrotic tissue. With the exposure of the infecting organism, such agents as mercury and salvarsan would be much more effective.

CONTRIBUTION TO THE STUDY OF THE VALUE OF QUININIZATION IN THE ERADICATION OF MALARIA

A. J. ORENSTEIN, M.D.
Superintendent of Sanitation, Rand Mines, Limited
JOHANNESBURG, TRANSVAAL, SOUTH AFRICA

My excuse for adding this paper to the already rather voluminous literature on malaria prevention is that it embodies the result of a unique experience, and one which, I feel, should be recorded.

My principal duty in Daressalam was to institute a campaign against malaria, and although my training has been almost entirely along the lines of attack on the anophelines (in Panama), I was under the impression, formed from the perusal of Claus Schilling's article in Ross' "Prevention of Malaria," that the method of Koch, introduced in Daressalam by Ollwig[1] in 1901-1903, has been successful in so far as it has at least considerably reduced the incidence of malaria.

The results of my study of the conditions in Daressalam have been embodied in a report to the imperial governor of German East Africa, but I was impelled to the writing of this paper by the appearance of Henson's article,[2] and the wish to show, by citing the results achieved by such an attempt, the difficulties in the way of reducing malaria to any reasonable extent by systematic quininization in a community of considerable size. Let me say here that I do not wish to be understood to the effect that the attempt should never be made, that this method of prophylaxis stands condemned as useless. It may have a cerain degree of usefulness, but it is, much to my regret, a very insignificant degree when applied to a permanent community of considerable size in a country where anophelines capable of transmitting malaria abound, and where, in addition, changes of population due to immigration serve to introduce more or less continuously gamete carriers.

---

[1] Ollwig: Die Bekämpfung der Malaria, Ztschr. f. Hyg. u. Infektionskrankh., 1903, xliii.

[2] Henson, Graham E.: Man, the Principal Etiologic Factor in the Perpetuation of Malaria, with Special Reference to the Endemicity of the Disease in the Temperate Zone, THE JOURNAL A. M. A., May 2, 1914, p. 1374.

Daressalam is a town of about 23,000 inhabitants, of whom approximately 1,000 are whites and Goanese, and the remainder mostly Swaheli of Negro-Arabic descent. The town is divided into practically two settlements: the white quarter, situated along the beach, and the native quarter, farther inland. To the east of the town is the Indian Ocean, to the south the harbor and Geresani Creek, a rivulet divided from the harbor by a dam and forming behind it a swamp about $^8/_{10}$ of a square mile in area. This swamp and the creek itself are prolific anopheline producers. The distance from the dam to the center of the town is about a mile.

In the very center of the native quarter are two large pools, one permanent, and the other containing water only during the rainy seasons, of which there are two annually. Both of these breed anophelines. One of these, to which reference will be made later, known as Karavanserai Pond, has recently been cleaned out and the banks trimmed, and it is being periodically treated with a phenol preparation. While thus treated it has remained free from mosquito life.

Then there was also, until very recently, a swamp, heavily infested with anophelines, about a mile long and 50 yards wide, in a valley on the very edge of the native town, with a branch toward a small European suburb. This swamp drains into the Msimbasi rivulet, the banks of which are also breeding grounds for anophelines during the dry seasons, and which winds its way in close proximity to the native town.

Across the narrow inlet to the harbor, and less than a mile away from the town, are a number of mosquito-breeding pools and swamps.

The town has no public water supply, nor any sewerage system.

There are about 200 wells, most of these badly covered and containing anopheles larvae. The European houses mostly have pits, into which the sewage is water borne. For this service water tanks are installed under the roofs, few of which are free from mosquito larvae. In addition, anopheles larvae were found in roof gutters.

In the rainy season pools of water, which stand for weeks in many instances, form in numberless places on streets, lots and in yards, and very soon mosquitoes breed in these.

Ollwig arrived in Daressalam apparently firmly believing in the soundness of Koch's theory[3] that malaria can be eradicated by attacking the parasite within the human host. He also believed, as he states in his articles in the *Zeitschrift für Hygiene und Infectionskrankheiten* and in private letters to Koch, since published, that a campaign against the mosquito in Daressalam was certain to be fruitless. He lays particular stress on the opinion of an unnamed "expert engineer" that the most prolific anopheles-producing area, the swamp at the mouth of Geresani Creek, is undrainable. Let me here remark, by the way, that a survey showed this swamp to be drainable, and that when I left Daressalam the creek and swamp were practically free from mosquito larvae, as a result of clearing the creek and ditching, which was done only on a small experimental scale because of the absence of funds.

Ollwig therefore instituted his campaign on the lines of an attack on the parasite in the human host, and this campaign is, so far as my information goes, still continued; at least, it was being continued when I left Daressalam in March of the present year.

The campaign is carried out on the following lines: Blood specimens are taken from all natives employed or living within the European quarter and in the immediately adjacent area. "Thick" smears are made, stained with Giemsa stain and examined. All those whose blood shows the presence of malaria parasites are given 1 gm. of quinin daily for six days and 1 gm. twice a week for ten weeks. The quinin is given in solution and is taken in the presence of a trained nurse.

The accompanying tables show the results accomplished. They have been compiled by Dr. Manteufel of the Daressalam Research Institute. The figures are from carefully kept records, and are not subject to the usual errors of such compilations.

TABLE 1.—MALARIA AND HEMOGLOBINURIC FEVER—MORBIDITY AND MORTALITY AMONG EUROPEANS IN DARESSALAM

		Morbidity		Mortality	
Fiscal Year	Population	Cases	Percentage of Population	Cases	Percentage of Population
1903-04......	377	168	44.5	0	0
1904-05......	350	141	37.1	3	0.8
1905-06......	657	355	54.0	4	0.6
1906-07......	851	287	33.7	6	0.7
1907-08......	827	268	29.8	6	0.7
1908-09......	743	342	48.0	3	0.4
1909-10......	750	506	67.5	5	0.7
1910-11......	930	460	49.5	10	1.1
1911-12......	1,024	667	65.2	11	1.1

TABLE 2.—INCIDENCE OF MALARIA INFECTION AMONG THE NATIVE POPULATION OF DARESSALAM BASED ON BLOOD EXAMINATION

	Adults		Children	
Fiscal Year	Examined	Infected Per cent.	Examined	Infected Per cent.
1904-05.......	8,000	10	None examined	
1905-06.......	No examinations made			
1906-07.......	14,752	7.5	3,234	18.9
1907-08.......	15,263	15	4,352	27.0
1908-09.......	28,267	14	3,747	33.4
1909-10.......	17,889	21	5,563	29.4
1910-11.......	15,960	18	4,136	27.7
1911-12.......	24,917	17	4,800	25.1
1912-13.......	19,782	20	3,308	32.0

Manteufel in his paper,[4] from which the tables are abstracted, says:

> When the above-mentioned expedition [Ollwig's] commenced its work in Daressalam, the Europeans were already in the habit of using mosquito bars on beds. However, the use of mosquito gauze for the protection of dwellings, and the taking of quinin prophylactically, as well as measures against mosquito pest, were only gradually introduced during the following years. In considering the influence of Koch's method upon the malarial morbidity of the European population, the above-mentioned factors must naturally be taken into consideration.

Now, the objection may be raised that the quininization was extended to only a portion of the population. The answer to this is that it represents a comparatively steady part of the population: house servants and artisans, who are less subject to migration than the traders, porters and agricultural laborers, who make up the remainder of the population of Daressalam. It follows that the results obtained among these people would be rather better than the average.

[3] Koch, R.: Die Bekämpfung der Malaria, Ztschr. f. Hyg. u. Infektionskrankh., 1903, xliii.

[4] Manteufel: 12 Jahre Malariabekämpfung, etc., Ztschr. f. Hyg. u. Infektionskrankh., 1913, lxxvi.

It is recognized, of course, that by leaving the bulk of the population untreated, the chances for infecting the treated portion remain very good.

An experiment was therefore instituted by me to determine the effect of treating all the inmates of a closed community.

For this experiment the negro pupils of the Daressalam Trade School, who live in dormitories and do not come into contact with the outside population, were selected. The school is in the European quarter. Five days after the school was opened, April 5, 1913, blood specimens from all the pupils were examined. One hundred and thirty-one of these were natives of Daressalam; of these sixty-six, or 46.8 per cent., had malaria parasites. One hundred and twelve came from the country; of these fifty-two, or 45.5 per cent., were infected.

All those found to be infected were put on the routine treatment with quinin, and this treatment was continued until Oct. 29, 1914. November 11, the blood of all was examined; 26.4 per cent. were infected with malaria.

The school was closed for the Christmas holidays. Jan. 15, 1914, again five days after the school was opened, 254 pupils were present. Of the 152 who spent the holidays in Daressalam, fifty-one, or 37.4 per cent., were infected with malaria. Of the 102 who spent the vacation in the country, thirty-seven, or 36.2 per cent., were infected with malaria.

A parallel inquiry was carried out. Oct. 3, 1913, 100 adults and fifty children living in the vicinity of the mosquito-breeding pond mentioned before, Karavanserai Pond, had their blood examined by the same person who examined the blood of the schoolchildren, and who had no idea whatsoever of the purpose or nature of the experiment. None of those examined had ever taken quinin prophylactically, and the subjects were taken at random from the huts in the vicinity. Of the adults thirty-two harbored the parasites of malaria (32 per cent.); of the children twenty-six were infected (52 per cent.).

The pond was cleared of vegetation, the banks trimmed, and the water near the banks treated every ten days with a phenol preparation. The work of clearing was completed in November, 1913. Feb. 26, 1914, again 100 adults and 50 children were taken at random from the population residing in the vicinity of the pond. None of these had had quinin. The blood smears were examined by the person who made the first examination. Of the adults fourteen, or 14 per cent., were infected with malaria; of the children sixteen, or 32 per cent., a decrease of 18 and 20 per cent., respectively.

Among those treated with quinin according to the Koch-Ollwig method, the decrease in a community under ideal control was 13.9 per cent.

It is to be noted that the climatic conditions remained practically constant during the period covered by the inquiry. It is also to be noted that the control of the one breeding area did not by any means eliminate anophelines from the vincinity from which the subjects were drawn. The number of anophelines was reduced, however, to quite a marked extent in such areas.

I want to draw attention to one other factor in connection with the experience in Daressalam with the Koch-Ollwig method.

In the past two years the energetic medical adviser to the governor, Generaloberarzt Dr. Meixner, has had quite a number of measures introduced, all of which tended to decrease the number of anophelines in Daressalam. Unfortunately, conditions are such that Dr. Meixner and his associates are not in a position to carry into effect all the measures against malaria that they rightly consider necessary. The power of the able and zealous officers is greatly curtailed and hampered in East Africa, and their efforts are rendered almost sterile by passive and active resistance, lack of funds and "red tape" in volumes beyond the comprehension, I fear, of the average American.

A COLLOIDAL COMPOUND OF STRYCHNIN AND ITS PHARMACOLOGY *

HUGH McGUIGAN, M.D.
CHICAGO

The migration of drugs in the body, and consequently their action, is largely dependent on their diffusibility through colloidal membranes and their interaction with colloidal bodies. Since I wish to present the action of a colloidal compound of strychnin, it may be of interest at first to give a brief summary of the properties of colloids.[1]

In 1861, Graham found that not all substances acted in the same way when their solutions were separated from water by a parchment membrane. Crystalline substances like sodium chlorid, potassium iodid, sugar and the like passed through, while substances like gums, starches and proteins did not. Those that passed through he called crystalloids, those that did not, colloids.

This difference in diffusibility is perhaps the most striking distinction between the two classes of substances; it is not, however, the only one nor is it an absolute one, since all these bodies diffuse to some extent, at least on longer standing.

THE NATURE OF THE COLLOIDAL SOLUTION

Various facts indicate that colloidal solutions are not true solutions but more of the nature of suspensions of fine minute particles of one form of matter in another. The solid particles are separated so that they do not come in contact with each other and are known as the disperse phase. The liquid molecules touch each other and are for this reason called the continuous phase of the colloid. All colloids are made up of these two phases—disperse and continuous. A difference in the size of the particles causes a difference in the refraction of light and consequently a difference in the appearance or color of the solutions. In the crystalline state it is well known that copper sulphate is blue, but if this be finely powdered it is white. Similarly the red oxid of mercury becomes yellow when more finely divided. For the same reason a colloidal solution of gold may be pink, red or purple in water and blue in organic solvents. The ultramicroscope also shows that many colloidal solutions contain fine particles.

---

* From the Laboratory of Pharmacology, Northwestern University Medical School.

[1] This summary is taken mainly from an Introduction to the Chemistry of Plant Products by Haas and Hill, Longmans, Green & Co., London and New York, 1913, p. 273.

The fact that colloids contain these particles suggested a reason for their not diffusing through a membrane, and to explain this the mechanical or filtration theory states that colloids do not pass through simply because the particles are too large. There are some known facts, however, such as the passage through one kind of membrane of a colloid which will not dialyse through another of different composition, which prevent the acceptance of this theory as the only process involved in dialysis. For this reason some chemists advance a chemical theory which holds that the passage of a substance through a membrane is due to the latter playing an active part in the process. Kahlenberg asserts that the substance which passes through a membrane is soluble in the membrane. This theory might be also used to explain the selective affinity of tissues for drugs and the ability of tissues to break up such weak colloidal compounds as strychnin with kaolin.

The nature of the solvent is also important. A substance may be crystalline in one medium and colloidal in another. Gallic acid in water acts like a colloid, while in glacial acetic acid it is crystalline. While gold may be pink, red or purple in water, and blue in organic solvents, it is ruby red in glass. Sodium chlorid is white, but blue rock salt is considered a colloidal solution of sodium in crystalline sodium chlorid. Sodium chlorid also may be obtained in colloidal form in benzene, while in water it is decidedly crystalline. Soap is colloidal in water but not in alcohol.

GEL FORMATION

Colloidal solutions readily undergo change, and unless conditions exist either for their preservation or renewal they soon deteriorate. The emulsions of the pharmacist "crack" and precipitate. The precipitation form of a colloid is called gel, the dissolved form, sol. Since both dissolved and precipitated forms of colloid may exist for many solvents, the terms "hydrosol," "hydrogel," "alcosol" and "alcogel," etc., are used to indicate the kind of solvent—water, alcohol, etc. If the precipitate or gel be one that cannot go into solution again, the action is said to be irreversible. If, however, the change is only temporary and through change of temperature or the like it again goes into solution, it is said to be reversible.

TYPES OF IRREVERSIBLE AND REVERSIBLE CHANGES OF COLLOIDS

1. Spontaneous precipitation: Some colloids like silicic acid or pharmaceutical emulsions, after keeping precipitate spontaneously.

2. Gel formation due to altered concentration: An ether solution of collodion on evaporation will form a gel. Fruit juices and agar gel on evaporation due to the presence of a colloidal carbohydrate-pectin. Gelatin, a protein substance prepared from tendon or bone, gelatinizes on evaporation of its solution. All of these changes are reversible with heat.

3. Coagulation by heat. This change is well known in urinary analysis in the heat test for albumin; also well known in the cooking of eggs. The action is irreversible.

4. Coagulation by enzymes. The well-known coagulation of the emulsion milk by rennet and by various plant enzymes is an irreversible reaction. The suspensoid colloids resemble closely the enzyme, catalase, in many of their reactions.

5. Precipitation by electrolytes: The colloids of the blood or urine may be salted out by the addition of varying amounts of different salts; usually a large amount is required. Other colloids, especially suspensoids, may be precipitated by mere traces of an electrolyte. Thus colloidal iron is precipitated by extremely minute amounts while emulsoids, like milk or blood, require large amounts.

6. Precipitation by other colloids of opposite sign: Colloids are known to carry electric charges, and it is this that enables them to remain in solution. When neutral they are precipitated. The proteins of the blood are amphoteric, that is, they carry charges of either sign. Colloidal kaolin is negatively charged and colloidal ferric hydrate positively. The last two will mutually precipitate each other. One of the best methods of removing the proteins of the blood for the determination of the blood-sugar is to mix the blood-serum or laked blood with colloidal iron, in slight excess. The blood thus treated takes on the character of the added colloid but still remains in solution. On the addition of an electrolyte bearing an opposite charge such as sodium sulphate or magnesium sulphate, the positive charge on the iron is neutralized and in precipitation it carries down the protein with it. For a similar reason ferric salts are used in the purification of sewage water. The negatively charged particles of the sewage are precipitated by the positively charged ferric hydroxid hydrosol. It has also been suggested that the neutralization of toxin with antitoxin, and the phenomenon of bacterial agglutination, may be regarded as the mutual precipitation of two colloids.

THE PROTECTIVE POWER OF COLLOIDS

Many organic substances such as gelatin and pectin bodies, when added to inorganic colloidal solutions, protect these from precipitation by electrolytes. As an explanation it has been suggested that the suspensoid becomes covered with a layer of the gelatin or pectin body and in a measure insulated with a coating of the added body whose character it takes on. Suspensoids so protected or insulated may be evaporated to dryness and again redissolved. This property of increased stability is valuable in the preparation of some of the colloidal solutions of silver and mercury used in medicine.

In like manner colloids protect sensory nerves from the action of acids, bitters, corrosives, etc. Sugar dissolved in mucilage tastes less sweet than in water, and acids in colloidal mixtures are less appreciated, as is observed in many fruits. The raspberry contains more acid and less sugar than the currant, but in the former the acid taste is concealed by the presence of large quantities of colloids so that the raspberry is regarded as a sweet fruit and the currant as an acid one. For the same reason ice cream does not taste so cold as frozen water (Cushny). One of the most common measures in the treatment of corrosive poisoning is the administration of colloids in the form of milk or eggs, because of this protective property. Charcoal, Fuller's earth or Lloyd's reagent would also lessen the rapidity of absorption.

CLASSIFICATION OF COLLOIDS

Two classes are recognized—suspensoids and emulsoids. This classification is based largely on the properties and composition of organic and inorganic colloidal solutions. Organic colloids are sticky and viscous. Inorganic colloids are never viscous. This difference is accounted for by assuming that the disperse phase of the suspensoids consist of solid particles in a liquid medium, whereas the disperse phase of the viscous colloids consists of liquid particles suspended in a more dilute solution or liquid medium.

Emulsoids.—Serum may be regarded as a type. The ultramicroscope reveals no distinct particles. Whether this is due to the particles being too small or not having a refractive index sufficiently different from that of the liquid in which they are suspended is not known.

The assumption that emulsoids are made up of one liquid suspended in another would to a certain extent explain their viscosity. The lack of a sharply defined surface of separation would account for their lack of marked electrical properties and their indifference to electrolytes as compared with suspensoids. A relatively great concentration of an electrolyte is required for their precipitation, while a trace precipitates a suspensoid. If a suspensoid be added to serum the latter takes on the property of the suspensoid and is then readily precipitated or dragged down with the suspensoid on the addition of a trace of an electrolyte.

Suspensoids.—These are perhaps of less importance in medicine and biology than emulsoids, but because our kaolin strychnin compound comes under this head a brief description of their properties is given. The method of their preparation sustains the assumption that they are electrically charged, and the ultramicroscope reveals the presence of solid particles. By analogy some of these properties are thought to apply to the emulsoids.

They may be prepared: (1) by the disintegration of metals by an electric current under water; (2) by the reduction of metallic solutions with reducing agents; (3) by the passing of hydrogen sulphid through arsenious acid, whereby the arsenic trisulphid instead of being precipitated remains in colloidal solution.

It is natural to suppose that in the method of preparation by an electric spark the particles should be electrically charged and that these particles, being charged with the same kind of electricity, repel each other and so keep in solution — or suspension. If electrolytes are added, the charge may be neutralized and the suspensoid precipitated. This explains why suspensoid colloids cannot be kept for any length of time unless carefully freed from electrolytes by dialysis. This property of neutralization of colloids by electrolytes and the neutralization of a positive by a negative colloid may explain the phenomenon of absorption which some colloids exhibit and which concerns us directly in the kaolin strychnin compound.

ABSORPTION

When a solid body is introduced into a solution the dissolved substance tends to accumulate at the point of contact between the solution and the solid. To all such cases of purely surface absorption the term "adsorption" is applied. This property is exhibited by wood charcoal to a large degree, and charcoal has long been used in chemical analysis to clarify solutions and to absorb gases. It has also been used in medicine to absorb gases from the stomach. Other colloids such as fuller's earth and china clay have been similarly used, and it is from fuller's earth that Lloyd's reagent is mainly prepared.

COLLOIDAL STRYCHNIN

The preparation known as Lloyd's reagent was prepared by J. U. Lloyd[2] from fuller's earth. It has the property of completely removing alkaloids from neutral and acid solutions. The reagent is essentially hydrous aluminum silicate. According to Waldbott[3] it has the approximate composition given in Table 1.

TABLE 1.—APPROXIMATE COMPOSITION OF LLOYD'S REAGENT

	Per Cent.
Water	17.41
Silicon dioxid	55.30
Aluminum oxid	9.82
Ferric oxid	14.80
Calcium monoxid	1.58
Carbon dioxid	undetermined

He also found that heating to 130 C. (266 F.) does not destroy its activity, but red heat renders it inert. Other colloidal materials, among which are colloidal arsenious sulphid and colloidal silicic acid, plainly precipitate quinin sulphate.

The use of this reagent for the separation of alkaloids has been investigated somewhat in detail by Gordin and Kaplan.[4] Because of the rather firm combination which the substance forms with alkaloids and the fact that it has been advised as a means of concealing the unpleasant taste of quinin, it was thought advisable to investigate its pharmacologic action. For this purpose Professor Gordin kindly furnished me with a colloidal combination of strychnin with Lloyd's reagent. The strength of the sample was 4 gm. of strychnin sulphate precipitated with 60 gm. of the reagent. The final product when dried weighed 65 gm.

Since the product contains about 6.15 per cent. strychnin sulphate, one is surprised to find that it is rather tasteless, and only after holding it in the mouth for some time does the bitter taste develop. It is this concealment of the bitter taste and its use for this purpose in pharmacy that makes the investigation advisable. As already reported by Dr. Gordin,[4] the colloidal precipitate acts very much like strychnin diluted with an inert substance. In fact, it has the typical colloidal property of delaying and lessening the effect of the strychnin.

In determining this I used frogs of about the same size and compared the action of pure strychnin with the colloidal form. The time of the onset of tetanus was noted in each case, and the amount of pure strychnin corresponding to the colloidal form estimated. This method has a limited application, but it shows beautifully the lessening of the tetanic dose and marked changes in the rate of absorption. The tables are self explanatory. The amount of colloidal strychnin is given in terms of strychnin sulphate, which is 6.15 per cent. of the amount of kaolin precipitate used. Equal volumes of fluid were used in each injection. The injections were made into the anterior lymph sac.

In comparing these two tables we find that where $\frac{1}{50}$ mg. of the pure strychnin produced tetanus in about an hour, the same amount in a colloidal form was without effect and that about four times the amount was required to produce tetanus in this time. The weakening effect is much more marked in the stronger colloidal suspensions. One twenty-fifth mg.

will produce tetanus in about the same time as 3.6 mg. or about ninety times as much of the colloidal compound. It is quite apparent, therefore, that this method will not give us the relative strengths of the preparations. It does show, however, the retarding action of the colloid. This difference in the apparent strength of colloids on dilution is perhaps not given the weight it deserves in the biologic standardization of drugs.

TABLE 2.—EXPERIMENTS WITH PURE STRYCHNIN SULPHATE

Weight of Frog, Gm.	Amount of Strychnin, Mg.	Time of Onset of Tetanus, Minutes
27	1/5	3.5

23 aver. weight of 10	3.6	32
20 aver. weight of 4	4.8	31

The difference between crystalline and colloidal strychnin is undoubtedly due to a retarded absorption. This can be lessened to such an extent that the rate of excretion may be nearly equal the rate of absorption, when no action would be expected. Other colloids have the same effect and it is well known that strychnin in mucilage is not nearly so quickly absorbed through the frog's skin as strychnin in water. O. H. Brown[5] has reported a colloidal albumin combination of strychnin whose properties are similar to the compound which I have described.

All of the animals that received the larger doses of the colloidal preparation died. Those that received the pure strychnin in smaller doses, but which produced tetanus in the same time as the larger colloidal doses, recovered. The colloidal combination, therefore, apparently acts mainly by delaying absorption, and if given in larger amounts is only a little less toxic than the pure alkaloid.

When administered by mouth the action is also delayed, but if the amount given contains a fatal dose of strychnin, tetanus is somewhat delayed and it requires a little more to cause death. The main difference is in delayed action due to delayed absorption. Cats and dogs react similarly to frogs. The exact diminution in the toxicity we have not measured, but it is not great.

CONCLUSIONS

The action of strychnin when combined with Lloyd's reagent is retarded. In this respect the reagent modifies the action in a manner similar to other colloids. The combination is broken up in the body and the typical strychnin action exerted. The toxicity of the alkaloid is somewhat lessened owing to delayed absorption, but the main effect is a retarded action.

THE INTRASPINAL TREATMENT OF SYPHILIS OF THE CENTRAL NERVOUS SYSTEM WITH SALVARSANIZED SERUM OF STANDARD STRENGTH

REPORT OF CASES *

HANSON S. OGILVIE, M.D.
Assistant Physician The Neurological Institute
NEW YORK

The purpose of this communication is to describe a method of preparing human serum containing a known quantity of salvarsan and suitable for employment intraspinally in the treatment of syphilis of the central nervous system, and to report a series of fifteen cases treated with such a preparation.

Recently Marinesco and Minea[1] reported having treated twenty patients with serum prepared in a somewhat similar manner, but in which neosalvarsan was used instead of salvarsan. Their work was started about the same time (November, 1913) as that herein reported. Reference will be made later to this article, and to a subsequent one by the same authors.

In support of the rationale of intraspinal treatment there are reasons which readily commend it to those who are familiar with the anatomic and physiologic conditions existing in the central nervous system. While necessarily a delicate procedure, and one that requires the greatest care and thoroughness of technic, the method may be considered free from hazard when the essential precautions are carefully observed. There can be no doubt in the minds of those who have followed the developments of the past few years that, in so-called parasyphilis or metasyphilis, we are dealing with either active syphilitic disease of the central nervous system, or the results of such a process. It is in the former class of cases only that we may hope to achieve success with any form of therapy. The findings of Noguchi and Moore,[2] and subsequently of others, have removed all doubt as to the true etiology and pathology of paresis and tabes.[3] The indications for a rational therapy have been definitely established. We are confronted with the task of dislodging the *Treponema pallidum* from the poorly vascularized regions of the brain and spinal cord. That the perineuronal and perivascular lymph-spaces are in direct communication with, and a part of, the subarachnoid space has been demonstrated. Dandy and Blackfan[4] in their experiments in producing artificial hydrocephalus, have shown that when phenolsulphonephthalein is injected into the subarachnoid space, only faint traces can be demonstrated in the thoracic and right lymphatic ducts even after an interval of two hours, whereas it appears in the blood in three minutes, and at the end of two hours from 35 per cent. to 60 per cent. has been excreted by the kidneys. This experiment indicates that the subarachnoid space and its accessory perineuronal and perivascular lymph trabeculae are not a part of the general lymphatic system of the body. It also shows that there is a free passage of spinal fluid into the blood-stream. The reverse is not true, however, for substances introduced intravenously and intra-arterially do not enter the cerebrospinal fluid. Tilney and Woolsey,[5] in a series of extremely important and interesting studies in vital staining, introduced solutions of trypan blue subcutaneously, intra-arterially, intravenously, and intraspinally. By the first two methods they found that the skin and thoracic and abdominal viscera stained readily; but the central nervous system, on the other hand, remained entirely free from stain. Given intravenously, the stain reached the dura mater and the pia, but did not penetrate into the nerve-tissue. Even after the use of *twice the quantity of the solution and a concentration three times as great* as that used in the first two methods, there was but little evidence that the dye had traveled into the substance of the brain and cord. After an intraspinal injection, however, *using only one-tenth the strength of dye solution* used in the first two experiments, the meninges were not only found to be deeply stained, but the dye had penetrated deeply into the nerve-tissue and through the walls of the veins and capillaries, even reaching the endothelium of the latter. Microscopic examinations of sections showed that the stain had traveled along the trabeculae of the pia.

These results suggest strongly the necessity for other than intravenous administration of salvarsan if we are to reach the diseased areas in syphilis of the central nervous system, other than gummas and endarteritis. The cells of the choroid plexus are secretory in character. To them is due, in a large part, the elaboration of the spinal fluid, although Dandy and Blackfan have shown that the ventricles of the brain also play a part in the secretion of this fluid. It is well known that only a few substances and these of the most simple character, such as urea and sodium chlorid, normally pass from the blood into the subarachnoid space. The question of the presence of salvarsan in the cerebrospinal fluid after an intravenous treatment is one on which investigators differ. While the majority have obtained entirely negative results, a few claim to have detected small quantities of arsenic. There can be no doubt, however, that the impermeability of the fluid secretory apparatus accounts for the comparative inefficiency of other than subarachnoid administration of curative agents in diseases affecting the meninges and adjacent nerve-tissue. Flexner,[6] in his work in epidemic cerebrospinal meningitis, Lamar,[7] in pneumococcic meningitis, Wollstein,[8] in influenzal meningitis, and more recently Flexner and Amoss,[9] in poliomyelitis, have demonstrated beyond a doubt that diseases of this type cannot be controlled except by subarachnoid therapy. Syphilitic meningo-encephalitis and meningomyelitis differ in no way from other diseases of these parts in so far as the method of treatment to be employed is concerned. While potassium iodid, mercury, and salvarsan intravenously, are of unquestioned benefit in many cases, not infrequently resulting in rapid amelioration of symptoms, they are rarely sufficient to eradicate the biologic evidences of active disease as shown by the findings in the spinal fluid. Until this is accomplished, and permanently so, our therapy is inadequate and an additional means of attack seems therefore very desirable.

We are indebted to Swift and Ellis[10] for the original work in intraspinal treatment of syphilis of the nervous system. Their method was to use the blood removed from a patient one hour after the intravenous administration of salvarsan. At this time the serum possesses the maximum spirocheticidal action and the minimum irritative qualities. The results obtained by Swift and Ellis in the treatment of tabes and cerebrospinal syphilis were extremely good. In this country a number of men, including Fordyce, Ayre, Tilney, Hough, McCaskey, Fry, Myerson, Byrnes, Cotton, Esper, Draper, Cutting and Mack, and Ogilvie, have employed the method in treating paresis as well as tabes and cerebrospinal syphilis. With the exception of Myerson, who discredits the method in both theory and practice, the consentient opinion of these men is that the results so far obtained, in all but the hopelessly irreparable cases, are very encouraging.

Efforts made to introduce solutions of neosalvarsan intraspinally have not met with very encouraging results. Swift and Ellis[11] found that solutions containing from 0.1 to 1.5 mg. produced marked lymphocytosis in the spinal fluid of monkeys, indicating that the drug was intensely irritating to the meninges. In this work they used 40 per cent. serum as a vehicle. Solutions containing 1.0 mg. of salvarsan produced a lymphocytosis of over 1,000 cells per cubic millimeter in every case, while in one monkey 3.2 mg. caused paralysis of the hind legs. Wechselmann[12] found that 0.1 mg. of salvarsan in solution of from 1 : 500 to 1 : 800 produced convulsions and subsequent death in dogs when given intracranially. Less concentrated solutions were better borne. He later[13] reported having treated two paretics and two cases of congenital syphilis intraspinally with doses of neosalvarsan ranging from 0.5 to 3.0 mg. without ill effects. Marinesco[14] reported severe reaction following the use of 5.0 mg. of the drug in a concentration of 1 : 800. Eight out of thirteen patients treated had vesical retention or incontinence. Three had paresis of the lower limbs and one had anesthesia below the site of puncture. Berger,[15] in a series of experiments on twenty-five dogs, found that a solution containing 1.0 mg. produced death when given intracranially. At necropsy even doses of 0.5 mg. had produced severe irritation at the site of the injection. This was evidenced by congestion and infiltration of the surrounding tissue, minute hemorrhages, etc. Only 0.1 mg. in a 1 : 10,000 solution could be given without irritation. Beriel[16] reports the death of three out of four paretics treated intracranially and intraspinally. Two of these received 2.0 mg. of neosalvarsan. One suffered no ill effects after 1.0 mg. and 2.0 mg. and appeared to be somewhat improved. Two of those who died were treated intracranially. Ravaut[17] reports no ill effects in nine patients receiving 63 treatments. He used from 4.0 to 12.0 mg. of neosalvarsan in isotonic sodium chlorid solution. His clinical and serologic results are vaguely summarized. Marie and Levaditi,[18] treated 14 patients and of this number five died within a month. Two others showed evidence of severe local irritation, vesical retention, paresis of the lower limbs, etc. Out of the total number treated there was improvement in one case. Jeanselme, Verne and Block,[19] treated five cases of tabes, four of paresis, and one of latent syphilitic meningitis. They record no unfavorable sequelae other than temporary increase of tabetic pains, rise of temperature and general weakness. They used from 0.25 to 5.0 mg. doses. Clinically their results are inconclusive. They found a reduction of the cell and globulin content of the spinal fluid in most cases, and the Wassermann reaction influenced in four out of five tabetics. Lorenz[20] reports fifteen cases treated intraspinally with neosalvarsan dissolved in 0.4 per cent. sodium chlorid solution. In ten cases there was a reduction of cells, in eight, decreased globulin, and in four the Wassermann was changed to negative. He used from 0.03 to 0.06 mg. of the drug at each treatment and believes this method less dangerous than the Swift-Ellis. In the work of Marinesco and Minea,[1] referred to above, the authors used neosalvarsan in human serum. The serum was first inactivated by heating at 56 C. (100.8 F.) for thirty minutes. From 6.0 to 12.0 mg. of the drug was then added and the combination heated at 37.5 C. (99.5 F.) for forty-five minutes. Six out of twenty cases of tabes and latent syphilitic meningitis showed improvement in one way or another. There was no improvement in the remaining fourteen cases. There was no parallelism between the changes in the spinal fluid findings and the clinical results obtained. Transitory retention of urine was noted as the chief unfavorable sequela. Later the same authors[21] report having treated twenty-one cases of paresis intracranially with serum prepared in a similar manner. There were signs of improvement in seven cases and death in one. They used as much as 1.0 mg. of the drug in only 5 c.c. of the patient's serum. In this series they record epileptiform attacks, rhythmical spasms of the legs and a transitory hemiplegia on the side opposite the point of injection, following treatment.

From a study of these results one can but conclude that, while apparently well borne in a small percentage of cases, neosalvarsan administered subdurally in any vehicle is attended with far too much hazard to warrant its use, even if the clinical results obtained were more encouraging. It is well known that both salvarsan and neosalvarsan attain their maximum spirocheticidal power only when in combination with blood-serum, and, as Swift and Ellis[22] have shown, this action is enhanced by heating at a temperature of 56 C. for thirty minutes. The heating of neosalvarsan at this temperature is impracticable because of its instability, and therefore its use is prohibited in any work that attempts to salvarsanize a serum in vitro. Recently Stühmer[23] has shown that salvarsanized serum, unheated, exerts a curative action for twenty-four hours in mice infected with trypanosomes, and a protective action for forty-eight hours, whereas, if the serum is heated at 56 C. for thirty minutes the curative effect is prolonged for three days and the protective influence for four days. He believes, with Swift and Ellis, that the heating of a salvarsanized serum in this manner is absolutely essential to promote the biologic and chemical changes necessary to attain the highest possible curative efficiency.

Convinced of the value of the Swift-Ellis method, from observation of results in some 200 treatments, but believing that, as in the employment of all other anti-syphilitic medication, the maximum efficiency would more readily be attained if we were able to increase or decrease the strength of our curative agent, I undertook, in November, 1913, to prepare in vitro a serum of known salvarsan content that could be safely administered intraspinally.

TECHNIC

The technic employed is as follows:

> About 50 c.c. of blood are drawn into a centrifuge bottle by means of a MacRae vacuum needle. The bottle is immediately placed in a large centrifuge and the fibrin and cellular elements are thrown down. It requires a speed of about 3,000 revolutions for fifteen minutes to produce a perfectly clear serum. It is rarely necessary to centrifuge more than once if the blood is freshly drawn, but the process should be repeated if the serum is not absolutely free from cells and fibrin. To 15 c.c. of serum is then added the amount of salvarsan to be given. This is done by mixing the salvarsan as for an intravenous treatment, using freshly distilled and boiled water, and bringing the total quantity up so that each 40 c.c. of the solution will contain 1.0 dg. (0.1 gm.) of the drug. Each cubic centimeter of this solution will then contain 2.5 mg. of salvarsan. With a 1 c.c. pipet, graduated into tenths, the desired amount can be readily measured from 0.25 mg. upwards. *In adding the sodium hydroxid it is of the greatest importance to use only the exact amount required to very faintly alkalinize the solution.* When this has once been determined by testing with litmus paper the sodium hydroxid should always be added quickly, and not drop by drop. *It is also very important that the temperature of the salvarsan and serum be the same when the two are mixed.* The serum is then gently agitated to thoroughly mix the two and is placed in a thermostat at 37 C. for forty-five minutes. From this it is placed in a thermostat at 56 C. for thirty minutes. It is now ready to be given intraspinally and it should be used as soon after preparation as possible. *Under no circumstances should a serum be used that is more than three hours old.*

The lumbar puncture is done with the patient lying on his side, the back flush with the edge of the bed, and the thighs flexed on the abdomen. Spinal fluid to the amount of 15 c.c. is permitted to flow through the cannula of the puncture needle, and the serum is then introduced by gravity from the barrel of a glass syringe. I have not found that the intraspinal pressure is of sufficient importance in the average case to require its measurement before and after treatment. In the absence of any evidence of extreme pressure the practice of simply removing the same quantity of fluid as of serum to be introduced has proved to be entirely satisfactory. After a treatment the patient is kept in the recumbent position, without pillows, and with the foot of the bed elevated, for four or five hours. The bed is then lowered, but he is not permitted to get up for from thirty-six to forty-eight hours, depending on the nature of the reaction following.

In the cases herein reported a total of seventy-five treatments were given. The reactions observed have been chiefly in the form of root pains in the lower extremities. These followed in about 50 per cent. of the treatments, varied considerably in intensity, and were invariably more marked in tabetics in whom lightning pains had been a prominent symptom. In three tabetics with vesical insufficiency, this symptom was temporarily increased with the pain. In one paretic who had not previously had bladder trouble, there was retention of urine necessitating catheterization for several days following a dose of 3.5 mg. Another paretic developed vesical and rectal incontinence, with numbness and weakness in the lower extremities, within six hours after a treatment with the same amount. In this case the patient got out of bed a few minutes after the treatment was given and walked about the room. The severe reaction that followed was attributed, in part, at least, to the probability that the erect posture had prevented the serum from properly diffusing within the spinal canal, and had caused an irritation of the roots in the dependent part of the dural sac. With the exception of this patient, who, although slowly improving, has not yet completely recovered, the reactions have all been temporary. In several tabetics and one taboparetic there was accentuation of the ataxic symptoms coming on several days after a treatment. In every instance, however, these symptoms slowly disappeared, and the patient's condition was eventually improved over what it had been prior to the treatment. When pains have followed a treatment they have usually responded to the ordinary anodynes given for the relief of tabetic crises. Occasionally it has been necessary to give morphin hypodermically. In only one case was there any elevation of temperature following a treatment, and this disappeared in twenty-four hours. In 50 per cent. of the treatments there was no reaction of any kind beyond a slight temporary weakness.

As will be seen by the table in Case 4, as high as 4.0 mg. of salvarsan was given at a treatment. In this instance there followed a temporary retention of urine and severe root pain. Although numerous other instances show a dosage of 3.0 and 3.5 mg. I would particularly emphasize the importance of keeping the dose within 1.0 mg. The treatments given with relatively small amounts of the drug were well borne, and the clinical improvement was more marked than when larger doses were used. This was very noticeable in Case 1, in which the patient showed the greatest improvement while on small doses. It would seem that nothing is to be gained by using larger quantities of the drug, and, in addition, the possibility of injury to the nerve-tissue is reduced to the minimum when the dose is kept within the above mentioned limit. *For repeated use, from 0.25 mg. to 0.5 mg. is the safest and most effectual dose to employ.* The giving of heroic doses does not contribute to the efficacy of the treatment, but, on the contrary, not only minimizes its value as a therapeutic measure, but may entail grave danger to the patient.

The following reports[24] must be considered as purely preliminary, since sufficient time has not yet elapsed for proper observation of the cases. In order to present them as concisely as possible, only brief abstracts of the examinations and analyses made before and after treatment will be given.

REPORT OF CASES

Case 1.—Tabes. Man, aged 41, married, salesman, was seen Nov. 15, 1913.

Symptoms.—Patient has difficulty in walking; marked ataxia; general weakness; periodic root pains; loss of position sense in feet and legs; paresthesia; numbness in feet and legs; hypersensitiveness to hot and cold water. Duration, three to four years, steadily worse.

History.—Patient had syphilis ten years ago. Primary and secondary manifestations. Orthodox treatment for three months. From February, 1912, to October, 1912, he received fourteen intravenous treatments of salvarsan and neosalvarsan, and reacted badly to each; absolutely no improvement.

Examination.—Patient is poorly nourished, weight 116 pounds. Gait and station very poor. Uses heavy cane; walks with difficulty. Easily fatigued. Knee-jerks and ankle-jerks absent, right and left. Pupils: 2 mm., round; fixed to light; very sluggish to accommodation. Position sense in feet and legs, nil. Hypesthesia in feet, calves, and post-thighs.

TABLE 1.—RESULT OF TESTS AND TREATMENT IN PATIENT 1*

Analyses	Cerebrospinal Fluid	Blood Date	Blood Reaction

		6/ 9/13	—

* In these tables ++ equals complete inhibition; —, negative.

Examination.—June 2, 1914: Objective: Areas of hypesthesia in feet and legs are very markedly diminished. Patient's position sense is only faintly impaired, at times appears to be perfectly normal. Nutrition greatly improved. Musculature firm. He has gained 8 pounds in weight. Gait and station very markedly improved. Subjective: Patient states that he feels better than at any time since the onset of his trouble. He is able to walk from six to eight miles without the aid of a cane, and without undue fatigue. He has been absolutely free from pain and girdle sensations for more than three months.[25]

Case 4.—Postman, aged 23, single, seen Feb. 10, 1914.

Symptoms.—Patient shows marked weakness of lower extremities; ataxia, very marked; vesical insufficiency; almost constant dribbling of urine; pains in arms and legs, not severe in character but practically constant. Duration three and one-half years, steadily worse.

History.—Patient had genital ulcer four years ago. No secondaries of any kind. Six months later developed bladder weakness and difficulty in walking. All symptoms were pronounced within a year. In November, 1911, was given two intravenous treatments of salvarsan.

---

[24] For lack of space only four case reports are given here. The full series will be found in the author's reprints.

[25] He has had nine intraspinal treatments; no salvarsan by vein; no mercury or potassium iodid. The improvement was most noticeable when he was receiving small doses, that is, under 1.0 mg.

Examination.—Patient is very poorly nourished; musculature soft and flabby. Weight 110 pounds. He is unable to walk more than twenty feet without assistance. Even this requires a great effort. Position sense in lower extremities is nil. Marked incoordination both manual and pedal. Knee-jerks and ankle-jerks absent. Pupils: 3 mm. round, very sluggish to light; to accommodation normal.

† On this date there was temporary retention of urine.

Examination.—June 1, 1914: Objective: There is definite improvement in the pupillary light reflex. Other reflexes unchanged. Coordination improved in both upper and lower extremities. His station with eyes open is very good; with eyes closed poor. His gait, although markedly ataxic, has improved so that he walks very well with the aid of a cane. He has gained 8 pounds. Muscles of his lower extremities are much more firm. Subjective: He is able to walk the length of ten city blocks with but little fatigue. He can get on and off street cars without difficulty. He has no trouble with his bladder other than occasional difficulty in retaining urine if bladder is not emptied promptly. He has had no tabetic pains for the past six weeks. He states that there is a definite improvement in his position sense in his feet and legs.

Case 9.—Paresis. Man, aged 46, married, merchant, seen Nov. 3, 1913.

Symptoms.—Patient is wildly maniacal. He has been in this condition practically constantly for the past nine months. For the past four months it has been impossible to keep a stitch of clothes on him, and he has lived in a room devoid of all furniture except a bed. He fights his attendants and raves and curses at the top of his voice. He is tractable only in the presence of his family physician.

History.—No history of syphilis obtainable. Seven years ago patient suddenly developed diplopia which disappeared under mixed treatment. He suddenly became violent nine months ago and was immediately committed. During this time he has had a number of intravenous treatments of salvarsan given at irregular intervals whenever his condition would permit.

Examination.—Knee-jerks and ankle-jerks diminished; R > L. Pupils about 2 mm., irregular margins, practically fixed to light. He is unusually well-nourished. It is difficult to make a thorough examination on account of his excited condition. He is oriented as to place and person but very vaguely so as to time. He talks in a rambling, disconnected manner.

Examination.—May 1, 1914: There is definite improvement in patient's condition. During the greater part of the time he is quiet and tractable. For the past month he has dressed himself each day and walks about the grounds of the sanatorium with an attendant. Otherwise there is no change in his mentality.[27]

* In this course of treatment the Swift-Ellis method was used. There was no change in his mental or physical condition. Patient was so resistive to treatment that it was necessary to precede each intraspinal injection with morphin and hyoscin hypodermically.

† Exogenous (Swift and Ellis).

‡ Serum of standard strength was used in this series of treatments.

Case 11.—Paresis. Man, aged 44, married, broker, seen Feb. 12, 1914.

Symptoms.—Patient has thick, slurring speech; defective memory; depression, epileptoid attacks; feeling of numbness in backs of hands, wrists, arms and forearms; irritability; childishness; numerous signs of slow mental deterioration. Duration, about eighteen months. First symptom was an epileptoid attack while in his office. Since then he has had numerous similar attacks; loss of consciousness, clonic and tonic twitchings, generalized.

History.—Patient had syphilis eighteen years ago. Genital chancre, no secondaries. Local treatment only. Within the past year he has had one intravenous treatment of neosalvarsan with potassium iodid and mercury by inunction irregularly. He has been unable to attend to business for some months. During the past week he had several epileptoid seizures within twenty-four hours and was dazed and disoriented the entire day. He has failed rapidly in every way during the past three months.

Examination.—Patient has typical paretic speech defect. It is often difficult to understand what he says. He shows a marked confusion of details covering the past six to eight months. There is a coarse tremor of the hands, tongue and at times the facial muscles. He is dull and stupid. Knee-jerks: right, normal; left, diminished. Ankle-jerks diminished. Deep reflexes of arms, normal. Pupils: round, 2 mm. fixed to both light and accommodation. His station and gait are normal.

---

[27] It is interesting to observe that there was no change whatsoever in the patient's condition while he was on the Swift-Ellis treatment, that there was an interval of over two months between this course of treatment and the four treatments with serum of standard strength, and that the serologic findings were rapidly influenced by the latter treatment.

TABLE 11.—RESULT OF TESTS AND TREATMENTS IN CASE 11

Examination.—May 27, 1914: Objective and subjective: Patient is entirely free from all his original symptoms. He has not had an epileptoid attack since his first treatment. His speech is normal. He has no tremors. Mentally he is bright and alert. He has gained in weight and his general health is better than at any time in the past two years. The numbness of which he complained in his hands and arms has entirely disappeared. The deep reflexes are unchanged. The pupils are still fixed to both light and accommodation.

SUMMARY

From a study of these cases it will be seen that the laboratory evidences of active syphilis, as shown by the Wassermann reaction in the blood, and the cell-count, globulin content and Wassermann reaction in the spinal fluid, were reduced in every instance to a greater or less degree, and that, in the majority, there was a concomitant clinical improvement. As to the permanency of these changes one must necessarily hold a conservative view, since it is yet far too early to draw any definite conclusions. It seems reasonable to believe, however, that those cases that have responded favorably, both clinically and biologically, can be controlled with proper supervision and sufficient treatment.

The work is only begun. It is of interest at this time chiefly in that it demonstrates the practicability of giving salvarsan in small doses intraspinally without jeopardy to the patient. The importance of keeping the dosage within 1 mg. cannot be too strongly emphasized. The relatively small amounts of arsenic found in serum salvarsanized in vivo (according to the method of Swift and Ellis) suggests that its spirocheticidal properties are not wholly dependent on the salvarsan content, but probably also on the formation of some substances in the blood-serum, with the nature of which we are as yet unfamiliar. It was, therefore, in an effort to preserve, so far as possible, the principles of the Swift-Ellis method, that the plan of first incubating the serum at body temperature for forty-five minutes was evolved.

105 West Seventy-Second Street.

Its Value.—There is nothing of which men are so fond, and withal so careless, as life.—Bruyere.

THE PREVENTION OF COMMUNICABLE DISEASES IN GENERAL HOSPITALS *

D. L. RICHARDSON, M.D.
PROVIDENCE, R. I.

I cannot hope to present to you any scheme which will entirely prevent the introduction of transmissible diseases into hospitals. The object of this paper is to point out briefly how such incidence can be very materially diminished.

We must first take a more intelligent interest in this matter and provide the means for accomplishing better results. Very few American hospitals, either general or contagious, keep an accurate record of diseases contracted within the hospital and record them in their annual reports. At most, they make brief mention of any considerable outbreaks. This is an unfortunate state of affairs. How shall we make any progress until we face this problem honestly, publish our results, good and bad, and study the situation from the standpoint of facts, not theories? Such an endeavor will bear fruit and will be to the advantage of hospitals, for the incidence of infectious diseases to any considerable degree injures the local reputation of a hospital, diminishes its efficiency, and is a needless financial burden.

Before the direct consideration of the problem, I wish to emphasize a few principles which underlie the transmission of infectious disease and point out some errors which we have all been committing. We have been led to believe that the causative agent survives for a considerable period after leaving the human body and may be more or less widely distributed; that the entire room of an infectious patient and its contents—bed, bedding, etc.—are permeated by the organism causing the disease; and that such contagion may be wafted to neighboring rooms and buildings. Teachers and text-books have presented many examples of scarlet fever contracted from some article of clothing or toys used by a scarlet fever patient, years before. These are all fallacies, however, under which we have been laboring, and it is no wonder that efforts to control infectious disease have not yielded better results. The truth of the matter is that, fortunately for humanity, infective organisms, under ordinary conditions of drying, rapidly lose their virulence. Though we admit the claim of bacteriologists who tell us that they can resuscitate organisms after the lapse of considerable time, it is not proved that any one ever contracted disease from such sources. Indeed, there is much practical evidence against such a supposition, and to obtain results we must turn our attention to the most common ways in which infection actually does find its way into the individual living, for the purposes of this discussion, under hospital conditions.

Infectious diseases are kept alive in any community by exposure to frankly clinical cases, to missed cases which are unrecognized or unrecognizable, and to carriers. Infection is transmitted from these three sources to the well either by direct contact, or indirectly; that is, on commonly used articles, by insects, by water, milk, and perhaps other foodstuffs, especially the uncooked. Indirect infection occurs but rarely through an uninfected third person, and by clothing, etc. In all cases, the medium of indirect infection must have been freshly infected.

---

* Read before the Section on Hospitals at the Sixty-Fifth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1914.

In hospital practice it is commonly believed that visitors introduce infection. This, I believe, is another fallacy, though I admit that they may do so on rare occasions; however, it is not of any practical importance. Many curses are heaped on the hospital laundry. This is also a mistake, for linen which has passed through washers as it is done in hospital washing is well sterilized. In practically all cases, the infection is introduced into the hospital on patients who are suffering from unrecognized infectious diseases, on patients who are carriers, or on patients who are admitted during the incubation period and not removed until damage has been done. It also happens, occasionally, that nurses and maids are on duty when in an infectious condition and may give rise to an outbreak.

I shall discuss the means of preventing such introduction of infection under two heads: construction and management. In treating of construction first, I do not mean to give it primary importance. It is, however, a factor of some consequence, especially as it bears on facilities for proper management. If, for instance, every person admitted to a hospital had a separate room during his entire residence, there would be less likelihood of a general, extensive outbreak of infectious disease; but such construction would not entirely prevent transmission. It would diminish personal contact but not indirect contact, a process which is of great importance in a general hospital where nurses and physicians, perhaps with fresh, virulent secretions on their hands, pass from one patient to another.

The construction which I would advocate for children's hospitals and for those portions of general hospitals given up to the care of children, comprises two departments: an isolation division and a convalescent division. Hospitals or portions of hospitals which treat adults only, do not require enough provision for the isolation of all new cases, though there should be sufficient isolation facilities for infectious or suspiciously infectious cases.

The isolation division should consist of rooms containing not more than three beds each. Fifty per cent. of the rooms should be for one patient only, and the capacity of the division should equal one-third, or better, one-half the total capacity of the hospital for children, but a much smaller proportion to the adult capacity of the hospital. The objection that single rooms are lonesome is not valid if they are situated on opposite sides of a common corridor and have sufficient glass area in the walls to permit of patients seeing and talking to those in other rooms. The isolation wards should be concentrated, but it is not necessary that they occupy a separate building. They should be centrally situated to favor transfers, but enough cut off from the rest of the hospital that they will not be a thoroughfare. An old open ward may be cut up into cubicles or stalls so that the beds will be 12 feet apart on centers, and should be provided with a sufficient number of lavatories to make hand washing convenient. The ventilation of the isolation wards does not need any special attention above that employed in other parts of the hospital. Of the ward equipment I shall speak a little later.

The isolation rooms described above are designed for the detention of all children under 14 years for a period of one week, if possible, and for the isolation of all real or suspicious infectious patients. All suspicious cases should be sent here, certain less highly transmissible diseases for as long a time as necessary, and all frankly clinical cases of contagious disease, provided there is no infectious disease hospital in the community to which to send them. Just here I cannot refrain from condemning the practice of sending home cases of contagious disease during a hospital outbreak, only to spread it in the community. There is a real objection to a detention period for surgical cases, particularly for those who need immediate surgical attention. As a matter of fact, surgical cases are less liable to bring infection into the hospital than medical cases. The situation may be met by providing each surgical ward with a sufficient number of detention rooms, and by removing to the isolation division all cases which are really infectious or suspiciously so.

The convalescent division is the main portion of the hospital and is to be kept uninfected by means of the filtration process already described. It should comprise wards or rooms of not more than twelve beds, and better, only six to eight in wards for children. The rooms for adults may be larger. At the end of a week's detention, all children may be transferred to the convalescent wards, as well as all other cases which have been proved non-infectious or free from infection.

It is the management, however, which is of paramount importance, and perhaps the admitting officer is the chief factor in this connection. From any point of view, this officer is of great value to the hospital, and especially with relation to the introduction of contagious diseases in new patients and the careful supervision of all cases in the hospital. In addition to the usual qualifications, he should have had practical experience with infectious diseases, particularly with regard to diagnosis and methods of control. If he has been rightly taught, he will have learned that over and above the positive clinical cases of all acute disease, there are a large number of doubtful cases and many which are unrecognizable. Chapin believes that the number of missed cases equals or may exceed the true clinical cases. The admitting officer must be familiar with the clinical syndrome of the various infections, their probable incubation periods, the ways in which the infecting agents leave the body, and special modes of transmission. He must always remember that every acute disease whose clinical picture is not evident on admission is a menace to the hospital until the diagnosis is made. He must remember that all sore throats, rashes, nasal or aural discharges, vaginal discharges, and coughs occurring either in new patients or in convalescents, require isolation for observation. He must be alert in detecting suspicious symptoms and he must be ultraconservative in placing with convalescents any suspicious case.

The admitting officer should have the supervision of the isolation wards and should be given complete authority to transfer patients into them from the convalescent wards, as well as from them into the convalescent wards. The management of the isolation wards is of the greatest importance. It must be carried out along the line of surgical cleanliness. Infection should be confined to the rooms occupied by patients, while the corridor, utility rooms, etc., are expected to be free from infection. In order to carry out these measures successfully, the isolation wards must be in charge of graduate nurses who have had experience with infectious diseases and appreciate the importance of proper aseptic nursing technic. It may be necessary to have two graduates on duty by day, if the number of patients is large, and it is important to have a graduate on duty at night, for undoubtedly errors in technic are more liable to occur at that time than by day. Pupil nurses who have had their operating room training are best adapted for the work; they must also have had their training in infectious diseases, if the hospital affords such training, and must be carefully selected. The same nurses, observing strict cleanliness, may care for all the patients in the ward.

You may say that such extreme care is not necessary for the ordinary case, even if a child, as it enters the hospital. But that is just the point I wish to make; namely, that because of our limitations in accurate diagnosis, we may let infectious cases pass into the hospital; if, however, they are first placed in properly conducted isolation wards, you may be very certain that little or no damage has been done. The further value of this detention period is seen in the opportunity it affords for further observation, cultures, vaginal smears, and other clinical examination to determine diagnosis.

Some of the conditions which should be sent to the isolation wards are sore throats, vaginal discharges, rashes, coughs suspicious of whooping cough, unexplained temperatures, nasal discharges, congenital and acquired syphilis, gonorrhea in any form, open cases of tuberculosis, septic conditions, impetigo, ringworm, cerebrospinal meningitis, anterior poliomyelitis, typhus fever, and all suspicious cases. Add to these all frank forms of the common contagious diseases, such as diphtheria, scarlet fever, measles, rubella, chicken-pox, whooping cough, etc., if the hospital must continue to care for them. Remember, however, that measles and chicken-pox are the most difficult contagious diseases to care for by aseptic nursing.

In order to confine the infection to the rooms occupied by the patients, they must be kept within their individual units, and everything must be surgically clean when it leaves the room. Certain equipment is necessary in order to accomplish this. The rooms should be provided with lavatories having forearm or foot valves; this is very important. There should be sterilizers for dishes, utensils, and bed-pans and urinals. There must be proper receptacles for refuse of all kinds, particularly things soiled with infectious discharges, all of which should be burned. The isolation rooms may contain from one to three beds; in the latter case, the beds should be from 10 to 12 feet apart on centers, in order to afford ample working space about them. The three beds in the same room may be utilized for different conditions, barring measles and chicken-pox, by barriering each bed separately so that the nursing force will know that they are to be treated as if in separate rooms. The many other details can be readily worked out, if one always remembers that patients suffering from different conditions must be physically separated and that strict surgical asepsis must be applied when passing from one unit to another. The danger of aerial transmission is a negligible factor. Fumigation of rooms is useless and a waste of time and money. The use of soap and water is sufficient. The nurses may live in the same home with the other nurses and eat in the same dining room, provided they change their uniforms and wash hands and face before leaving the ward.

There are several points in the general management of a hospital which I should like to emphasize. Nurses should be taught more about the transmissibility of disease and should be thoroughly imbued with the importance of cleanliness, both in protecting patients and in protecting themselves from infection. This should be taught them during their probation period. There should be a sufficient number of nurses, supplemented by nurse maids, to care for patients, particularly in children's, typhoid, and surgical wards. Many of the so-called precautions observed in all hospitals are truly of limited value. It is very important that there should be enough lavatory basins so that it will always be convenient for nurses and physicians to wash their hands frequently in running water. Every ward should have sterilizers for utensils, bed-pans, urinals, and dishes. Everything soiled with infective discharges should be carefully sterilized or destroyed. Nurses should be vaccinated against typhoid fever and small-pox. Printed instructions should be posted in all employees' rooms, stating how infectious organisms enter the human body, and itemizing the common ways based on the well-known fact that a large proportion of infectious diseases must enter through the oral cavity, so that everything must be kept out except food and drink, and these introduced with clean hands. As far as possible, wards should be under charge of graduate nurses, especially those in which children are treated. Head nurses should be taught to be always on the lookout for suspicious symptoms and should be authorized to barrier any case until the admitting officer has seen it. All new employees should have nose and throat cultures taken and all employees should be under watchful supervision at all times. They should never be sent on duty with sore throats or rashes or any acute illness, unless it is known to be non-infectious. Common drinking cups and common towels should be prohibited everywhere. Thermometers should be wiped and immersed for one minute in some antiseptic fluid before being used on the next patient. Soiled linen from infectious cases should be removed from the wards directly to the washers. The ambulance should be provided with clean blankets and pillow slips between infectious cases and the hands of driver and attendant washed. After the more highly infectious diseases, soap and water should be used on those parts of the ambulance which may have been touched by the patient. All new patients should have nose and throat cultures taken, and vaginal smears should be made on all female children.

These recommendations are based on four years' experience at the Providence City Hospital, in which a very large variety of highly transmissible diseases is treated and the problem of preventing patients contracting secondary diseases is much the same as in a general hospital, except that the danger is greater. I must not take time to develop further details or quote statistics about our results, but will refer you to the several hospital reports and articles published on our work.

SUMMARY

1. Infectious diseases are introduced into the hospital chiefly by new patients.
2. Well-equipped and well-managed isolation wards should be provided for all suspicious and infectious cases and for all children under 14 years during a detention period.
3. There should be very careful admission of all patients, nurses, and help, and supervision of the same.
4. There should be sufficient equipment for all wards and better teaching of nurses and help about infectious diseases.

Providence City Hospital.

ABSTRACT OF DISCUSSION

Dr. H. M. Bracken, Minneapolis: There is a great deal for a public-health man to know relative to the handling of infectious diseases, and the question of the proper hospitalizing of these patients is an important one. It certainly would be an advantage if we could house some of these patients in a general hospital, yet I presume it would hardly be safe for me to suggest such action. If handled in a general hospital it would have to be with as careful isolation as in a hospital set aside especially for that purpose, and sometimes this would be difficult. Dr. Richardson states that success in handling these cases depends largely on the individuals in charge and this is most certainly the case. I was pleased to note his attitude as to air-borne infection, and disinfection. As a matter of fact the spread of disease is chiefly dependent on personal contact with the infected. When it comes to the spreading of disease the whole thing depends largely on the nurse and the physician in charge. A great many patients are released too early. The sooner we throw fumigation to the wind the better. The ordinary method of fumigation conveys an idea of safety that does not exist. The proper care of the patient is important, while the burning of the so-called fumigating candles is a waste of time and money. I wish we were doing more in the way of hospitalizing the infectious-disease cases. It is a lamentable fact that, except in the larger cities, there is no proper hospital accommodations for such patients. Our knowledge of infection in relation to surgery revolutionized the hospital in its relation to surgery. In surgical work an individual is sent to the hospital to prevent his own infection. In preventive medicine we should send one individual to the hospital to prevent the infection of many others.

Dr. C. H. Cook, Natick, Mass.: How many physicians have seen a case of small-pox? I had service for six months in a small-pox hospital. Forty years ago I was willing to take my chances in diagnosing the disease, even mild cases of varioloid, but I would not to-day. I know the difficulties. If physicians have no opportunity to see these cases how are they going to become good diagnosticians? They read about them and that is all. I do not wonder that there is case after case of mild varioloid not recognized by the physicians. I do not think the general practitioner is to blame. One has to send for experts. I would have been willing forty years ago to serve, but I wouldn't to-day, although I have seen those cases. With regard to the way small-pox is carried, I have no explanation, but I want to state this fact: in an insane hospital, the extreme ends of which were 700 feet apart, one case broke out in each end. The patients had been there for years. I know this, for I had the care of the patients after they were admitted to the small-pox hospital. How did the infection occur?

Dr. William H. Walsh, Philadelphia: With the principles of the technic of contagious nursing, as set forth by Dr. Richardson, I am heartily in accord, but I believe that he is going too far in the matter when he declares it possible to nurse contagious diseases in an ordinary ward of a general hospital without the risk of contagion. Statements of this kind are misleading, for while it might be possible to carry out the rigid technic necessary for such work in Providence, R. I., it does not follow that the same work can be successfully done in other parts of the country, under different conditions. We all admire Dr. Richardson's work, but we realize that his hospital is a small one, and that the technic which can be successfully employed in a small institution is much more difficult to maintain in a large hospital. It might be considered, in many parts of the country, criminal malpractice to attempt the treatment of contagious cases in a general ward and I am exceedingly doubtful, in case an accident occurred, whether the excuse that a nurse had slipped up on her technic would be considered a mitigating circumstance. Dr. Richardson's whole theory depends on the infallibility of the nurse and we must not forget that nurses are only human and that in contagious nursing, as in any other occupation, there is a limit to the extent of human endeavor. The use of pupil nurses for this method of caring for contagious diseases would be almost impossible, for the reason that it requires a long, continuous training before nurses can be trusted in a ward with mixed infections; and it would therefore be necessary, if this technic were generally adopted, to dispense with the services of pupil nurses and depend entirely on graduates, thus materially increasing the cost. I did not learn from Dr. Richardson whether he would treat a case of scarlet fever and one of diphtheria in the same room, but I can most emphatically state that we would not attempt that in Philadelphia, where we have a staff of experienced nurses. Another point to be remembered in connection with municipal institutions is the fact that the nursing force is subject to sudden and extensive changes, and if such a thing should happen in an institution where Dr. Richardson's technic had been adopted, the whole system would be immediately turned upside down. I have recently learned that a number of smaller cities have attempted the treatment of contagious diseases in general hospitals, only to be met by dismal failure and considerable embarrassment.

Dr. H. O. Collins, Minneapolis: It has been stated that the usual method of disinfecting laundry is not reliable, that the sterilization process sometimes permits linen to go through without being disinfected. What method of disinfecting the linen of contagious patients is the best?

Dr. G. L. Kiefer, Detroit: Did Dr. Richardson, in speaking of the isolating of children under 14 years of age in a general hospital, mention the time?

Dr. D. L. Richardson, Providence, R. I.: One week.

Dr. G. L. Kiefer, Detroit: It does not seem to me that that answers the purpose, for the simple reason that a week does not reach the incubation period. We tried it out in one of the children's hospitals in Detroit, and lengthened the time of detention. The child may have been exposed some time before it came to you, or only the day before. One point Dr. Richardson made should be emphasized. It means more to me now than it did before I heard him say it, and that is with regard to the strict surveillance of all nurses so far as the possibility of their being infected is concerned. We have thought we practiced it, but I do not think we were careful enough. Supervision should mean personal inspection of all the employees at frequent intervals. Of course the answer to the gentleman who had the experience with small-pox, is that it was carried to the hospital. Our experience in Detroit with regard to the transmission of small-pox has been quite the opposite of that brought out in this discussion, and I am absolutely sure small-pox cannot be made an exception to these contagious diseases. For example, we put our cases of tuberculosis in a large building that had been occupied as a small-pox hospital. It was one building. There were separate entrances. At first the tuberculosis cases were put in the north wing and the small-pox cases in the south wing. There was never any small-pox in the tuberculosis hospital. We followed that up by having our tuberculosis hospital on the same ground, and never had a case come over to the tuberculosis side. Why some men still class small-pox as the one disease that can be transmitted through the air I never could understand. It is not different from any other.

Dr. Dana Hubbard, New York: New York handles between 75,000 and 82,000 cases of contagious diseases annually in a population of over five million people.

I have had something similar to Dr. Kiefer's experience, except that I attributed the infection to a central focus—in all probability, milk. Fly infection in small-pox hospitals must be considered. We took flies at North Brother island in 1892 and covered them with magnesia dust and flour and turned them loose; it was astonishing to see how many of these flies turned up in the kitchen. The hospital (Riverside) was built in units. The small-pox service is in a large, two-story brick structure, thoroughly screened, as we thought, with double doors at entrances, but the doors constantly being opened and shut let flies in and out. The small-pox patient, by reason of the pus odor, attracts flies, and it is difficult to keep them away from him. For eighteen months following the installing of screens we did not have a single case of small-pox develop in another ward. The foundling service gave us some bad cases of nasal diphtheria which attracted flies, and before the screens were installed small-pox appeared from time to time in this service. This was before the day of the recognition of the bacillus. Diphtheria broke out in our wards as cross-infection quite frequently and, in the small-pox service, more often than small-pox in the diphtheria service. Now, we are thoroughly screened and have very little trouble from cross-infection. I would not hesitate for a moment, if I had competent help, to put a case of diphtheria in any ward with any other contagious disease, as we do typhoid fever. I have seen diphtheria treated in Roosevelt Hospital in ward service without spreading the disease. I firmly believe that the strict aseptic handling of the patient proved that diphtheria could be treated in a general ward the same as typhoid. At the Chickamauga service in the Spanish-American war, we had typhoid fever by the hundred cases and I attributed its spread entirely to flies. Here the flies were smeared with magnesia dust and flour and turned loose and were caught in numerous other regimental camps. The toilets were open and unscreened. I believe typhoid fever in the Spanish-American war existed because of the failure to recognize the cause and to take proper precaution. I take exception to the elimination of fumigation. I do not believe we can say that fumigation is "not worth anything." Fumigation, properly done, will answer a good purpose. There are many instances where disinfection is necessary and can be properly done.

DR. J. P. SEDGWICK, Minneapolis: From my experience it is possible, with proper care in nursing and proper care of the hands, to prevent carrying these contagious diseases in a manner that we before thought impossible. There is a type of contagious disease which is frequently not considered such in hospital work, and which usually causes the infants more trouble than small-pox, diphtheria or scarlet fever. This type is what I might call, for want of a better name, the grippal infection, an infection of the respiratory tract particularly, which occurs frequently in children's wards. We have records in our wards in which the weight lessens with these infections and rises slowly after they are remedied, and we can follow these two together. We see this repeatedly. I think I can agree with one of the writers in the *American Journal of the Diseases of Children*, that these acute infections of the respiratory, urinary and gastro-intestinal tracts are more important to the hospital infants in causing a larger death-rate and holding back an increase in weight than are the common acute contagious diseases. The hospital grippal infections in infants, which are being studied so much by pediatrists, are important. Meyer believes that the well-known "hospitalism" of infants is due to these "grippal" infections.

DR. JOHN A. HORNSBY, Chicago: I am in almost constant receipt of inquiries concerning the proper means of taking care of the communicable diseases under the average conditions of a general hospital. We are not discussing ideal conditions for the care of the communicable diseases in institutions specially devised for them and handled by people specially trained over a period of years, but about institutions in the United States that are not equipped for taking care of these cases, but which, under the obligation of our newly conceived responsibilities, find themselves obliged to consider such. Goldwater and a good many of the best men in the hospital world think that no hospital of any kind ought to be permitted to exist unless it is prepared to take proper care of every case that comes to it, or of every disease that develops after the patient gets in; for instance, an eye hospital must take care of a pneumonia, or any other disease which develops. How is a hospital that is run for general purposes, to take care of any sort of sickness under crude equipment, going to handle those cases? Is it sufficient that we put a tapeline around the bed and practice Koplik's constructive isolation? Can we maintain it? Have we the nurses properly trained for it? Can we develop the technic of it among our medical men? Dr. Richardson's scheme is ideal; but I do not believe that the twenty-five- or fifty-bed hospital in Podunk can render such technical care of communicable diseases. Isolation is the thing, but we ought to think ahead a little to a time when they are about to build a hospital for Podunk. How should it be built so that they can take care of those cases in the light of our present knowledge of communicable diseases? The best way to do it is to isolate in the architecture of the building. Suppose, for instance, that we are building a hospital, and we have an area for communicable diseases, say four wards on two floors. Let us assume that we have a whole medical staff that is entitled to take care of patients; how would it do to have separation in the architecture and have different sorts of clothes for each one of the units? Suppose we have scarlet fever, diphtheria, and, let us say, small-pox. Why not have some brown clothes for scarlet fever? They have been sterilized and cleaned up and put in the lockers of the dressing-room to be there put on. Suppose the doctor puts on that brown suit, with head-piece, mouth-piece and gloves. He goes up with the brown clothes on to the scarlet-fever ward. On the same floor he has a case of diphtheria, across the hall. He goes over there, but the nurse says: "I am sorry, Doctor, but you have on the wrong clothes. Won't you kindly put on your diphtheria clothes?" That means that he has to go back, clean up, and take off the scarlet-fever clothes and put on the clothes used in case of diphtheria. I contended in one hospital that we have been building, that that sort of technic was ideal for the particular condition we had to meet.

DR. ROBERT J. WILSON, New York: The Schick test for determining if diphtheria antitoxin is present normally in the blood, is important with regard to the spread of diphtheria in the hospital. If no reaction follows, it means that there was one or two or three units of antitoxin in the blood; when we do give the injections to secure active immunization the antitoxin runs up immediately. The number of patients immune to all diseases all the time is very large, and it can be proved for diphtheria and inferred for scarlet fever, measles or any other infectious disease. To say that one cannot contract any disease by air-borne dust or exudates that have been recently deposited in the room, that is, within the length of time that we know the organism could not have died by drying, is contrary to scientific reasoning. If but little infectious material were in the room and no cases were susceptible no disease would be contracted, and, therefore, one could argue it was not air-borne; if out of many cases only one was susceptible and there were only a little infected dust, disease might not be contracted because those immune might inhale the dust and the non-immune would not get it. I am not going to consent to the non-air-borne proposition until it is proved that the organisms die instantly or within a reasonably short period of time after being deposited. No visitor is allowed from a home where there is contagious disease. In reply to Dr. Collins relative to the best way to sterilize the laundry; I think sterilizing washers give the best results; if you get the contents of the washer up to the boiling point all the germs that produce contagious disease are destroyed. In New York City we have a minimum period of quarantine—scarlet fever thirty-five days, measles five days from the beginning of the initial rash. We never discharge a patient who gives us reason to believe that infectious organisms are still retained in the discharges. Dr. Cook asked how you would educate all practitioners to be diagnosticians. It cannot be done, but every community should have in it one good diagnostician. Dr. Sedgwick referred to grippal infections. We found in the Willard Parker Hospital, about fifteen years ago, that some of our patients with very severe diphtheria were being carried off with bronchopneumonia, and we thought it spread from bed to bed; so to get around that condition we built stalls between every two beds in a ward and by this simple procedure the number of cases of bronchopneumonia was very much diminished. It has been proved that the droplets of sputum emitted by ordinary speaking will be suspended in the air for some time before they finally drop to the ground. Without intervention the slightest draft would carry them over to the adjoining bed; the wall prevents it.

Dr. D. L. Richardson, Providence, R. I.: Dr. Bracken spoke of carriers among visitors. These are, of course, a possible but I do not believe a very frequent source. If we rule out visitors to the children's ward under 14 years of age that would eliminate danger to a large extent. With regard to nursing, if one tries for oneself what nurses can do and will do regarding aseptic nursing, one's ideas will change. Relative to pupil nurses, we have a staff of graduate nurses and from twelve to fifteen pupil nurses who come to us and work in the diphtheria and scarlet-fever wards, and one isolation ward, and they stay with us only two months altogether, but you would be surprised at the intelligence and care they exercise. I grant that it would be a good deal better if you could have all graduate nurses, but the expense is sometimes prohibitive. If you can get nurses who have had operating-room training, and have had some experience, say in the third year of their course, and teach them the simple elements of absolute cleanliness, you can expect better results. I advise anybody who does not believe it to take a ward of six beds in an infectious hospital, and try it. That is the only way to be convinced. Dr. Kiefer spoke of a detention period of one week. I spoke of that merely as a working-basis which we have taken in our hospital. It is not long enough for measles, chicken-pox, etc., but it is a great help, because the numbers of cases that would be exposed just before admission to the hospital would be comparatively small. All hospitals ought to be screened. It makes no difference whether they are contagious hospitals or not.

The respiratory and intestinal conditions I did not speak of. Dr. Sedgwick brought that to mind. In the children's hospital some day we will carry out the same exact conditions throughout. Dr. Hornsby spoke of isolation in architecture. I do not at all agree with him in that. Theoretically, every infectious-disease patient that enters the hospital should have his own room, nurse and service. Practically, that is utterly impossible, and with a small or a large hospital, unless it is a very large community, they cannot afford to build either a hospital or a portion of a hospital for measles, another for whooping-cough and another for chicken-pox, etc. If hospitals are to furnish an asylum for infectious diseases, they must provide the most feasible plan. You cannot control infection unless you have careful supervision and absolute cleanliness. With regard to outside physicians coming in, we have a consulting staff, and I have failed to find a man who will not do as he is requested.

OIL OF CHENOPODIUM IN THE TREATMENT OF HOOKWORM INFECTIONS

ROBERT L. LEVY, M.D.
Assistant Resident Physician, Johns Hopkins Hospital
BALTIMORE

The majority of observers at present regard thymol as the vermifuge of choice in the treatment of uncinariasis. The work of Stiles and of the Porto Rican Commission has clearly demonstrated its value. The administration of thymol, however, is associated with certain very definite disadvantages: 1. It does not succeed, in a certain number of individuals, in eradicating the infection. 2. Its ingestion is accompanied in about 45 per cent. of cases by disagreeable after-effects, as has recently been pointed out by Stiles and Boatwright.[1] 3. In a few instances, it has produced fatal poisoning. 4. At present, owing to conditions brought about by the European war, the supply of thymol is limited and its cost high.

It seems desirable, therefore, to call attention to the use of a vermifuge which has apparently been entirely overlooked in this country in the treatment of hookworm disease and whose value in this connection has recently been pointed out by Schüffner and Verwoort.[2] The object of their investigations was to determine whether or not thymol deserves its reputation as an anthelmintic in uncinariasis, especially as compared with more recently suggested remedies. Accordingly, 1,457 infected individuals were put through two "cures" at intervals of several days, thymol being regularly alternated with one of the other preparations to be tried out. In this manner two parallel columns of statistics were obtained, one in which a group of patients had received thymol first, the other in which they had taken it second. So both drugs had the opportunity of demonstrating their action on untreated as well as on previously treated parasites. The strength of the anthelmintics was rated in proportion to the number of worms found in the washed stools.

As a result of these comparative studies Schüffner and Verwoort determined that the "coefficient of efficacy" of the various drugs investigated, was as follows:

1. Oil of eucalyptus, 38.
2. Beta-naphthol, 68.
3. Thymol, 83.
4. Oil of chenopodium, 91.

Cases of infection with both the New and Old World types of worm were included in their series. In no instance in this large number of observations were disagreeable symptoms noted, nor were there any signs of intoxication following the taking of the chenopodium. They conclude, therefore, that the oil of chenopodium, in view of its remarkable efficiency and its harmlessness, deserves a thorough trial in the campaign against uncinariasis.

CASE REPORTS

The following case, from the service of Prof. L. F. Barker, and shown before the Johns Hopkins Hospital Medical Society, Dec. 15, 1913,[3] afforded an unusually good opportunity for trying out the comparative efficiency of thymol and the wormseed oil. It is, as far as can be determined, the first report in this country, of a case of uncinariasis treated with oil of chenopodium.

Case 1.—O. C., a Norwegian sailor, aged 23, was admitted to the Johns Hopkins Hospital, Oct. 13, 1913, complaining of headache, general bodily pains and swelling of his legs. The present illness began in Mexico one month before admission. There, for the first time in the course of his wanderings, he went about barefoot. He soon developed a painful sore on the dorsum of the left foot, which discharged and resisted all efforts made to treat it. There was no itching of the foot. Shortly afterward the feet and legs began to swell and the patient felt weak and incapable of work. He entered a hospital in Mexico and remained there for three weeks, during which time he was given no medicine. The swelling of his legs disappeared, however, and he was discharged somewhat improved. Twelve days before admission here, his legs again began to swell, he felt feverish and weak, and there was moderate diarrhea, so he boarded a ship for this country and landed in Baltimore.

On admission, there was striking pallor, fever, tachycardia, brawny edema of ankles and lower legs and a pigmented scar on the dorsum of the left foot. He was extremely weak and very irritable. The blood showed: red blood cells, 1,660,000;

[3] Levy: A Case of Infection with Agchylostoma Duodenale Treated with Oil of Chenopodium, Bull. Johns Hopkins Hosp., 1914, xxv, 160.

white blood cells, 6,440; hemoglobin, 25 per cent. (Sahli). In addition, there were seen many hyaline and crescent forms of estivo-autumnal malaria. An examination of the stools revealed ova of *Trichocephalus dispar* and *Ankylostoma duodenale.*

The malarial infection was soon under control. The whipworm ova spontaneously disappeared from the stools following vigorous purgation. But the usual medication with thymol, as recommended by the Porto Rican Commission, failed to expel the hookworms, though the treatment was thrice repeated at intervals of one week.

Accordingly, the patient was given the oil of chenopodium essentially in the manner prescribed by Schüffner and Verwoort. He was starved for eight hours, at the end of which period he was given an ounce of Epsom salt. Two hours later 16 drops of the oil of chenopodium on a teaspoonful of granulated sugar were administered. This dose was repeated at two-hour intervals until three doses had been given. Two hours after the last dose of chenopodium the patient was given an ounce of castor oil, containing 50 minims of chloroform. On sifting of the stools collected during the next twenty-four hours, nineteen hookworms of the Old World type (*Ankylostoma duodenale*) were found. Ova continued to be discharged in the feces. On repetition of the treatment five days later, seven more hookworms were expelled and no ova could subsequently be demonstrated in the stools. Another course of chenopodium was given to make sure that no parasites remained; none were expelled. The stools continued free from ova. The man gained 30 pounds in weight. His blood on discharge showed: red blood cells, 4,110,000; white blood cells, 11,000; hemoglobin, 70 per cent. (Sahli).

A second case demonstrates in like manner the prompt success of the chenopodium when thymol medication had failed.

Case 2.—C. P., a South Carolina farmer, aged 33, entered the Johns Hopkins Hospital in the service of Prof. T. C. Janeway, Sept. 17, 1914, complaining of stomach trouble. He had previously been admitted to the hospital in September, 1906, with similar symptoms, which had appeared following an attack of "ground itch" earlier in the year. On the first admission, hookworm ova were found in the stools, and several thymol treatments were administered. Following therapy there was a gain of 6½ pounds in weight coincident with general improvement, and on discharge no ova were seen in the feces.

The present illness was a continuation of the gastric disturbance which had brought the patient to the hospital in 1906. After a period of about two years, during which he was relatively free from discomfort, there developed fulness after meals, belching and vomiting, associated with sweating, headaches, dizziness, dimness of vision and roaring in the ears.

Examination revealed a moderate secondary anemia, and an eosinophilia of 9.2 per cent. Ova of hookworm were seen in the stools.

The usual thymol treatment was ineffectual; ova continued to be discharged in the feces. So five days later the oil of chenopodium was administered as follows:

First Day: No supper. One ounce of Epsom salt at 8 p. m.

Second Day: 7 a. m., 9 a. m. and 11 a. m., 16 drops of the oil of chenopodium on a teaspoonful of granulated sugar; 1 p. m., 1 ounce of castor oil containing 50 minims of chloroform.

Unfortunately, the resultant stools were not carefully sifted and only one female worm (*Uncinaria americana*) was observed in a casual examination of the "castor-oil stool," in which the parasites are usually found. During the three weeks following the chenopodium medication, while the patient remained under observation, no ova were found on repeated stool examinations, and he left the hospital with a gain of 15 pounds in weight, much improved.

It is worthy of note that in neither case did the patient object in the least to the taste of the chenopodium, nor did he complain of any unpleasant effects following its administration.

Further experience is afforded in the following personal communication from Dr. C. G. Guthrie:

> During the past summer, which was spent in a hospital in Central America, an opportunity was presented of testing the efficacy of the drug (chenopodium) on a fairly large scale. Most of the patients admitted to the hospital were either Jamaican negroes or whites of the peon class. Among both of these the incidence of infection with intestinal parasites was extremely high; fully 80 per cent. harbored some form of parasite. Multiple infections were the rule, in one instance six types being present. Next to whipworm, the form of intestinal parasite most frequently encountered was the hookworm; both the Old and the New World types were found, the latter being the more prevalent variety.
>
> Thymol was the method of therapy in vogue at this hospital, and while it was, in the main, successful, many cases were observed that required repeated treatments, and a few in which three courses of thymol still left the patient heavily infected.
>
> Accordingly, it was considered desirable to try the effect of oil of chenopodium. The method of administration was patterned after that of Schüffner and Verwoort, except for the fact that the drug was administered in capsules. The criterion used for an effectual treatment was the disappearance of hookworm ova from the stools. The treatment was tried in about sixty cases, and the results compared with those obtained by other methods. These results, with the conclusions drawn, may be briefly mentioned as follows:
>
> 1. The treatment was well borne; no ill effects were noted and no complaints of subjective discomfort were elicited on careful questioning.
> 2. The treatment was successful in both Old and New World infections. It sometimes had to be repeated, but it practically never failed to eliminate some worms or to reduce the number of eggs in the stool.
> 3. It succeeded in cases in which thymol had been tried, sometimes repeatedly, and had failed.
> 4. When given in parallel series to unselected cases, the chenopodium seemed much more efficient than thymol.

OIL OF CHENOPODIUM

Oil of chenopodium, or American wormseed oil, as it is commonly called, is a volatile oil distilled from the fruit of *Chenopodium anthelminticum* Linné (of the *Chenopodiaceae* family), a roadside weed common in the United States, and most abundantly found in the eastern portions of the country. It has always been official in the Pharmacopeia of the United States. It is largely distilled in Maryland and is often referred to as "Baltimore oil" in contradistinction to the western or "Missouri oil" which has also played a rôle on the market. When recently distilled, it is of light yellow color, but becomes deeper yellow or even brownish by age.

It has a peculiar, penetrating, somewhat camphoraceous odor and a pungent, bitter, though not altogether disagreeable taste. Garrigues found it to be composed of two distinct oils separable by distillation; one of these has the formula $C_{10}H_{16}$ and is probably limonene. The other is heavier and possesses the formula $C_{10}H_{16}O$. A body having the formula $C_{10}H_{16}O_2$ has been recovered from the oil by Brüning.[4] Both in its general characteristics and pharmacologic action, it resembles closely the mother substance.

The oil has long been effectively used as an anthelmintic in the roundworm infections in children in a dosage of from 5 to 10 minims, two or three times daily for two days, to be followed by a brisk purge (Wilkins,[5] Brüning,[6] Gockel[7]).

---

[4] Brüning: Zur Kenntnis des amerikanischen Wurmsamenöles, Ztschr. f. exper. Path. u. Therap., 1906, iii, 564.

Its cost at jobbers' prices is from $2.50 to $3 a pound.

The account of the oil in the United States Dispensatory is concluded with the following statement: "Oil of chenopodium has in various cases acted as a lethal poison." In order to obtain further information concerning its toxicology, regarding which the available data are exceedingly scanty, the reported cases of chenopodium poisoning have been collected and are given in the accompanying table.

REPORTED CASES OF POISONING WITH OIL OF CHENOPODIUM

Case No.	Observer	Age of Patient, Years	Dose of Oil	Symptoms	Result	Remarks
1	P. T. T.[9]	6	Not stated; less than 1 ounce	Deep, stertorous breathing; small, weak, rapid pulse; eyes insensible to light or external objects; convulsive movements of right half of body; attempt at deglutition threatened *suffocation*	Death in 36 hours	Vial of what purported to be "Wormseed oil" obtained from a wandering quack; to be given in doses of 15 drops until worms were expelled
2	W. C. Paramore[10]	6	8 drops 3 times daily for 2 days; 8 drops on 3d day	Drowsiness; thirst; fever; nausea and vomiting; coma	Death in 4 days	Coroner's case; oil not followed by a purge
3	W. C. Paramore	3	6 drops 3 times daily for 2 days; 6 drops on 3d day	Drowsiness; thirst; fever; nausea and vomiting; spasms; coma	Death in 5 days	Member of same family as Case 2; no purge
4	W. C. Paramore	1	4 drops 3 times daily for 2 days; 4 drops on 3d day	Drowsiness; thirst; fever; nausea and vomiting; spasms; coma	Death in 8 days	Member of same family as Cases 2 and 3; no purge
5	T. R. Brown[11]	31	1½ ounces plus 30 drops of turpentine at a single dose	Vertigo; nausea and vomiting; deafness with buzzing in ears; periodic motor aphasia; staggering on attempting to walk; peculiar actions suggesting dementia; subsequently, spasm of right arm and hand, followed by right-sided paralysis; fever; convulsions; terminal icterus	Death in 5 days	Physician had ordered 1 ounce of castor oil and 20 minims of turpentine; prescription changed by neurotic patient
6	A. C. Pole[12]	2	2 teaspoonfuls in 1 afternoon	Prostration; restlessness; tachycardia; staggered on attempting to stand or walk; headache; abdominal pain; vomiting; deafness	Well in 5 days	Symptomatically treated; deafness gradually disappeared
7	I. C. Gable[13]	63	"Nearly" an ounce in divided doses in 1 day	Initial "peculiar symptoms" rapidly followed by coma, profuse perspiration and salivation; tachycardia; dilated pupils	Death next day	Necropsy: "No special symptoms in the stomach, though there was considerable smell of the oil about the abdominal viscera
8	Alfred North[14]	12½	1 dram	Next day heavy breathing; difficult to rouse; unsteady gait, with partial loss of coordination; frontal headache; ringing in ears; deafness; dulled mentality; 5 days after onset, coma, with weak, slow pulse; dilated pupils, sluggish to light, and vomiting; on 7th day, hallucinations; subsequently, steady improvement	Recovery in 2 weeks	Chenopodium given in a *mixture* so that exact *dose is uncertain*; partial persistence, at end of 2 weeks, of headache, deafness and tinnitus
9	Alfred North	10	About 1 dram	Nausea and vomiting; unable to walk or adjust clothing owing to ataxia; deafness, tinnitus and frontal headache	Recovery in a few days	Sister of patient reported as Case 8; given dose from same mixture; deafness still present after two weeks
10	Cited by North[15]	Adult	2 doses of "30 grains" each 3 hours apart	Found in coma	Death	No details given
11	A. K. Bond[16]	3	10 drops ineffectual; 2 days later ½ dram	Vomiting; stupor; pupils small; sweating; twitching of right hand; tachycardia; suppression of urine; râles in lungs	Death same day	
12	E. T. Ramsey[17]	61	1 tablespoonful	Numbness and tingling in hands and feet, followed by peaceful sleep; nine hours later, roused with difficulty; irrational; rapidly went into coma	Death same day	Patient a mentally deficient epileptic; administered overdose to herself

17. Ramsey, E. T.: Northwest. Lancet, 1903, xxiii, 325.

An analysis of this table brings out the following points:

1. Eight of the twelve cases occurred in children under 13 years of age.

2. Nine of the twelve cases ended fatally.

3. In seven instances, the individuals received what may be considered an overdose. Of the remaining five, the dosage is uncertain in two. In one of these (Case 1), what purported to be wormseed oil was obtained from a wandering quack, so that its exact nature is by no means certain. Furthermore, no limit was set as to the amount which might be given. In the *other case* (Case 10) we have only the account of a newspaper reporter to the effect that "two doses of thirty grains each were taken, three hours apart."

4. In the cases reported by Paramore (Cases 2, 3 and 4) death occurred in three members of the same family following the administration of what were apparently doses which may be considered within the limits of safety, though not followed by the usual purge. All were coroner's cases, yet no question was raised as to the amounts said to have been given by

the father, nor was there any inquiry as to the nature of the contents of the bottle. Paramore himself asks, "Are these fatal results an accidental coincidence, or are we to suppose that in these three children some peculiar idiosyncrasy existed, forbidding the use of the remedy?" To which the editor of the *Chicago Medical Times* replies:

> In the cases above reported the wormseed oil, which was probably the Oleum Chenopodii, was administered in doses at least one-third larger than are usually recommended. Another element which may figure in the case is the difficulty which persons unaccustomed to dropping find in accurately dispensing medicines by the drop, hence the possibility that these children may have even taken more than was thought or intended.

5. The symptoms of poisoning have made their appearance usually several hours after taking the oil. Nausea, vomiting, abdominal pain and headache have been the first warnings of trouble. These were soon followed by drowsiness, deafness and tinnitus aurium, the latter having been a prominent feature in several instances.[8]

Ataxia, with staggering on attempting to walk, is noted by four observers. In the fatal cases coma has rapidly supervened, with tachycardia, convulsions, and in one instance right-sided hemiplegia. These symptoms indicate clearly irritation of both gastro-intestinal tract and central nervous system.

Concerning the pathologic lesions present, no data whatsoever are available. In the one instance in which a necropsy was performed, there is only the note that "there were no special symptoms in the stomach, though there was considerable smell of the oil about the abdominal viscera." In animals experimentally poisoned with oil of chenopodium, Brüning[3] has found hyperemia and small hemorrhages in the mucous membrane of the stomach and small intestines, and, microscopically, pigment accumulations in the liver and the formation of cylindroid-like structures in the convoluted tubules of the kidney.

MODE OF ADMINISTRATION

A convenient schema, which may be followed in administering the treatment, is herewith given:

First Day: Liquid diet; 8 p. m., 1 ounce of Epsom salt.

Second Day: Omit breakfast and luncheon; 5 a. m., 1 ounce of Epsom salt; 7, 9 and 11, 16 drops of the oil of chenopodium on a teaspoonful of granulated sugar; 1 p. m., 1 ounce of castor oil containing 50 minims of chloroform. Soft supper.

Third Day: Resume full diet.

The treatment may be repeated at intervals of one week until ova can no longer be found in the feces. The worms are usually expelled in the "castor oil stool." It is desirable to add the chloroform to the castor oil, as it appears to assist in the narcotization of the worms in their passage through the intestinal tract. In children, the size of the individual dose of chenopodium as advocated by Gockel[7] in ascaris infections, may well be adopted as a safe standard in the therapy of hookworm disease:

From 6 to 8 years, 8 drops.
From 9 to 10 years, 10 drops.
From 11 to 16 years, 12 drops.
Over 16 years, 12 to 16 drops.

CONCLUSIONS

1. Oil of chenopodium is an effective vermifuge in the treatment of uncinariasis.
2. It is not unpleasant to take, its ingestion is followed by no disagreeable symptoms and it is cheap.
3. In therapeutic doses it is non-toxic.
4. Oil of chenopodium deserves a thorough trial in the campaign against hookworm disease.

I desire to thank Professors Barker and Janeway for permission to report these cases.

CONGENITAL PHTHISIS BULBI

WITH REPORT OF A CASE

AARON BRAV, M.D.
Ophthalmologist to the Lebanon Hospital
PHILADELPHIA

Phthisis bulbi as a result of some suppurative traumatic or non-traumatic uveal inflammation is not a very rare condition, but shrinking of the globe as a result of uveal inflammation *in utero* is very rare indeed, and deserves to be recorded in medical literature. The case which I am reporting has been carefully differentiated from other congenital abnormalities, such as microphthalmus and anophthalmus, and by a process of exclusion fortified by a microscopic examination of the ocular discharge the diagnosis of phthisis bulbi seems clinically to be certain.

The child was delivered by Dr. Rappoport. Labor was normal. No instruments were used. While trying to instil a 2 per cent. solution of silver nitrate into the child's eyes, the doctor noticed that there were practically no eyeballs.

At the request of Dr. Rappoport I saw the case in consultation at Atlantic City on the third day after birth, July 29, 1914, and found the following conditions: Baby is well developed; weighs about 10 pounds; has several erosions on the face. One on the chin had some suppurative appearance. Eyelids were normal but closed. There being no attempt at elevation, they were, however, easily separated. I separated the lids with lid retractors so as to get a good view of the orbital contents. Both orbits showed marked signs of inflammation and contained some pussy discharge. There were no extraconjunctival folds or adhesions, but the conjunctiva was very much congested. Deep down in the right orbital cavity there was a remnant of an eyeball the size of a large pea. Scleral tissue was easily recognized, in the center of which was a slight remnant of corneal tissue about 2 mm. No pupillary area could be determined; neither was there any iritic tissue noticeable. The stump was soft and quadrilateral in shape and still showed evidences of a retrogressive inflammation. The conjunctiva was red and congested, but did not show any signs of an anatomic anomaly. The left eye was also in a state of inflammation and the stump was much smaller than in the right eye. The stump here was so small that it could only be seen after the lids had been well separated with lid retractors, and was deep down in the apex of the orbit. It could not be palpated. The discharge in the left eye was more marked than in the right eye. Limbs, upper and lower extremities were normal; so was the trunk and head of the baby. Temperature of the baby by rectum was 101.

The parents are healthy and apparently free from any taint. The mother is a well-developed woman and has had two healthy children before. Mother was well during the period of pregnancy except for a pustular acne eruption which appeared about one month before delivery. This was probably an external manifestation of some deep-seated infection. The mother attributed the condition to maternal impression as she says her older child had been playing with a doll that had no eyes. The only other etiologic moment the family recalls is a fright of the mother during a severe thunderstorm which occurred about three weeks before delivery. It is hardly necessary to say that neither of these causes could be given any consideration. Everything points to a severe inflammation. At my suggestion Dr. Rappoport has made a microscopic examination of the ocular discharge of the infant, and he reports to me the presence of diplococci which did not respond to the gonococcic stain.

---

[8] Sexton: A Note on the Aural Phenomena Produced by Chenopodium Poisoning, Am. Jour. Otol., 1880, ii, 197.

There is no doubt in my mind that we deal here with a case of phthisis bulbi, resulting from a suppurative intra-uterine uveitis. The marked local inflammatory symptoms, the absence of any other anatomic anomaly, the pustular eruption on the mother four weeks before the delivery of the child, the presence of the diplococcus in the ocular discharge, and the appearance of the stump make the diagnosis of phthisis bulbi certain. Of course the number of cases of microphthalmus reported in the literature are many, but most of them were the result of some arrest of development.

Opinions on this subject are divided. Hirschberg, von Graefe, Samelsohn and Deutschmann advanced the theory of intra-uterine inflammation, while the developmental theory was defended by Hess and Treacher Collins. There is, however, a definite group of cases in which there can be no reasonable doubt that the condition is one of congenital phthisis bulbi. This is especially true of Schaumberg's[1] case in which the eye continued to shrink after birth. In my case the inflammatory cause is well substantiated by clinical evidence and laboratory findings.

917 Spruce Street.

A SEVERE CASE OF EXOPHTHALMIC GOITER, WITH COMPLETE RECOVERY WITHOUT OPERATION, REST OR MEDICATION

Edward Swasey, M.D., Worcester, Mass.
Oculist and Aurist to Worcester City Hospital

It may not be safe or profitable to draw conclusions from any one case of illness, either medical or surgical; and yet a single case may present some features of importance and interest that may render its history worthy of public record. I believe the following case is in this class:

Mary M. is now 24 years of age. When she was 12 I gave her glasses for a rather high degree of astigmatism. She has been under my observation at intervals for these past twelve years. Some five or more years ago her mother first noticed a growth in the neck. This rather rapidly increased in size so that the neck band of her dresses required frequent enlargement. The girl soon began to show signs of nervousness, was easily fatigued, and complained of palpitation on slight exertion. Soon the eyes seemed to enlarge and become prominent. She consulted her family physician who gave her some simple tonics for her evident weakness.

Some months later she came to my office to see if some change in her lenses was necessary. The change in her appearance since her last visit one year before was decided, for now there were all the classical signs and symptoms of a typical case of exophthalmic goiter. The eyes were bulging, so that a line of white sclerotic was seen between the iris and the upper lid. The swelling in the neck was firm and pulsating; the pulse was then more than 150 per minute, soft and compressible. The ear or hand over the cardiac area showed a large pulsating heart, in rapid action. In fact, all the signs and symptoms of a well-established case of Graves' disease were present. I have had the case under observation from that time to the present. I gave her no medicine, but for a time she had a simple tonic from her physician and also from one of the city dispensaries.

The chief interest in this case, I believe, is not that she has entirely recovered, and that all her symptoms have disappeared; but that during the entire duration of these severe symptoms she was daily at her work at the counter of one of the largest department stores in the city. She continued her tonics for a year or more in a somewhat irregular way, but finding no benefit from their use gave them up entirely. A year or more after she had given up all medication she began to improve, in that she felt stronger and more able to do her work; the heart action was less troublesome, the swelling of the neck less evident. This improvement has gone slowly but steadily on until now (for I saw her but a few days since) the neck is free from any swelling, and palpation reveals no thyroid enlargement; the pulse is strong, steady and under 80 per minute; the eyes have returned to the normal in position and appearance. She has never taken any of the modern powders or serums that are now given for this trouble. She has never taken any season of rest in bed, but, on the contrary, has taken no vacation, but worked on. In the months that the symptoms were at their worst I felt certain she would have to come to a surgical operation to save her from the severe toxemia that I thought might overwhelm her in a severe attack of diarrhea or fatal exhaustion; but she said she must keep at her work and would not listen to advice for an operation.

I have recently followed the case of a patient in whom the symptoms were not more severe than in this poor girl, and not so long in duration, that finally came to operation in the Johns Hopkins Hospital, but the patient survived the operation but a few hours. I have had for a number of years a patient who has the eye symptoms and enlarged thyroid. Both of these have been stationary for years.

It may be that cases similar to this are common, and in a somewhat careful search in the literature of the subject I find many recorded cases of recovery, of course; but I have yet to find the history of one with severe symptoms for many months and a total duration of more than five years, yet going on to complete recovery that has not had prolonged course of treatment, either by rest in bed, the use of the modern drugs, the application of some external treatment to the thyroid, the Roentgen ray, or one or all of these at different times. Hence I believe that the case of this patient who had no treatment, but just work, and plenty of it, and yet has gone on to complete recovery, deserves a place in the records of this serious disease.

The question may arise regarding the subsequent history of this patient. Will this great and prolonged activity of the thyroid finally result in an atrophy more or less complete and cause a myxedema? It will be interesting to watch the patient for a few years.

390 Main Street.

TRAUMATIC RUPTURE OF THE HEALTHY AORTA WITHOUT EXTERNAL SIGNS OF THE CAUSE OF DEATH

Gordon Grote Copeland, B.A., M.B., Toronto

Complete rupture of the healthy aorta without external signs of the cause of death is of sufficient rarity to warrant the publication of a synopsis of necropsy which I made recently.

A laborer, aged about 40 years, was struck by a large mass of falling earth which gave him a glancing blow on the back and knocked him down, though it covered only his legs. A few seconds later he was picked up dead, and was seen by a medical man in a few minutes who could find no cause externally for the sudden death. I examined the body a few hours later but saw no apparent cause of death. There was a large scalp wound on the forehead down to the bone, but the frontal bone was not fractured. The mouth, nose and ears were free from blood or foreign matter. There was a little frothy mucus in the back of the throat. There were several small bruises on the body, especially over the right loin, and a suspicion that the pelvis was fractured.

---

[1] Schaumberg: Dissertation, Marburg, 1881.

The scrotum was torn and the testicles lay loose between the thighs. There was practically no hemorrhage.

The face, tongue, gums and mucous surfaces generally were blanched, and suggested internal hemorrhage.

INTERNAL EXAMINATION

The diaphragm was about 4 inches above the intercostal notch, and did not communicate with the thorax; though it was torn at several places, the rents did not extend through the muscle completely. There were nearly 10 ounces of free blood in the peritoneal cavity. The liver was terribly torn and ruptured so as to admit the whole hand at several spots. The right kidney was torn, but the capsule was intact and the blood did not go into the pelvis of the kidney or the ureter. The bladder was intact although the pelvis was fractured from the symphysis through the body of the pubic bone. The peritoneal surfaces of the intestines and many of the blood-vessels going to them were torn. With these lesions the abdominal cavity should have been filled with blood.

The whole condition was explained when the thorax was opened. The left pleural cavity contained 38 ounces of measured fluid blood. Opening into this cavity were the gaping ends of the descending aorta, which was cut across as cleanly as with a knife. The ends were separated about 1 inch at the widest part and half an inch at the closest part. The rupture was at right angles to the length of the artery. The aorta was quite healthy; the intima was smooth and devoid of plaques and dilatations as far as could be seen or felt. The heart was firmly contracted and the chambers were empty. The valves were normal, as was the heart in every particular. The coronary arteries were patent for a distance of 2 inches. I passed my finger through the aortic valve (the heart being opened *in situ*), and at the proximal opening in the torn artery, my finger tip appeared. The distance from the aortic valve to the tear was about 3½ inches. The right lung was adherent throughout to the chest wall and was very hard to remove. All the lobes were fused and the organ was quite solid and non-crepitant; it resembled the stage of red hepitization of pneumonia. The left upper lobe was normal but the left lower contained a lot of coagulated blood. Aside from the injury to the aorta, the man would have died rapidly from the terrible hemorrhage that would otherwise have resulted from the injuries to the liver, mesenteric vessels, etc. What caused the rupture I am unable to say, though the idea of a force acting like a contrecoup seems tenable.

73 Bloor Street, East.

EXOPHTHALMIC GOITER AS A CLINICAL MANIFESTATION OF HEREDITARY SYPHILIS

Oscar Clark, M.D., Rio de Janeiro, Brazil

I have had the opportunity, during the last five years, of observing an interesting case of exophthalmic goiter in a woman, aged 24, in whom there can be no doubt that it is a late clinical manifestation of hereditary syphilis. The patient began about five years ago to suffer from palpitation and tachycardia, accompanied by violent attacks of nervousness, while her mother also called attention to a swelling of the neck. There was very little protrusion of the eyes.

Four years ago when I was first consulted (shortly before leaving on a journey to Europe, during which I was kept informed of the progress of the case), the clinical symptoms had become decisive and the syndrome grew steadily worse until the patient fell into a drowsy, almost comatose condition, with pulse over 200 beats, the sphincters quite paralyzed, with continuous vomiting lasting a fortnight. Dr. Sylvio Moniz, a well-known Brazilian physician, was summoned to the patient in this very bad condition and had the happy thought of trying the Wassermann reaction. To this he was led by the "Olympic forehead" and the *crâne natiforme*, being told also that the girl when 12 years old, had had several "epileptiform" fits. The Wassermann reaction was strongly positive, both with the patient's mother and with the patient herself.

With this diagnosis, Dr. Sylvio Moniz prescribed mercurial frictions and epinephrin (1:1,000 solution, 20 drops three times daily) to relieve the arterial hypertension and the vomiting; the latter rapidly ceased, while the patient had in two days recovered consciousness.

After eight days the pulse was just 150 and the goiter sensibly smaller, while the protrusion of the eyes was a little better. After thirty frictions the patient was much better both as regards the hyperthyroidic manifestation and the general health. The next month she was given two injections of salvarsan (0.3 and 0.6 gm.). By the third month she had quite recovered. Neither the goiter nor the protrusion of the eyes was to be seen. The pulse was 75 beats and the nervousness had disappeared.

The patient returned to North Brazil (she was at Rio de Janeiro), and ceased the mercurial and salvarsan treatment. Twelve months later, however, the Merseburger triad reappeared but a fresh recovery has been effected by the same treatment.

I think that this case is undoubtedly one of hereditary syphilis appearing late, as Dr. Sylvio Moniz made every laboratory test in order to exclude tuberculosis, malaria, etc. The father is dead, of what cause I am not aware; the positive Wassermann in the mother has been mentioned. The patient is from the best society and is virgin and there can be no suspicion of syphilis by contagion. She has never had any clinical sign of infection, but on the other hand, presents skeletal stigmata, and, as previously remarked, had epileptiform fits at the age of 12.

Therapeutics

PREVENTION IS GREATER THAN CURE

IX

PHYSICAL EXAMINATION AND PHYSICAL EXERCISE

When it is remembered that there are twenty million pupils in the public schools, large percentages (as previously stated) being defective in some form or other, it will not be surprising that the following recommendations for the physical examination of children, as distinct from medical inspection which will be discussed later, is urged. These recommendations seem more or less ideal, but they will come to be the rule, if not the law, nevertheless.

If it is agreed, as advanced by some thoughtful educators and physicians, that from the age of 6 to 8 the time should be devoted to physical culture directed by the public schools, and that book work should not begin until the age of 8, just what would be the method of procedure?

First, no sick child should be allowed in the public schools, whatever the age, and sick children should be immediately sent home to the care of their parents. Every child on entering the public school, we will say at the age of 6, should be carefully examined by a skilled physician. This is more than "medical inspection," which only seeks for contagious or transmittable diseases. The record of each child should be kept on a large card suitable for filing alphabetically. One side of the card should be filled out by the teacher with such data as name, residence, age, sex, nationality, height, weight; condition of parents (living or dead, and health), brothers and sisters (number and health); what diseases the child has had, besides a record of fits, headaches, asthma, hay fever, bilious attacks or attacks of abdominal pain (information on these subjects should be obtained from the parents by the teacher); the number of rooms in the tenement or house of the family, the number of windows in the sleeping room of the child, the number of persons sleeping in this room; and the kind of food and drink the child receives (question of coffee, tea, etc.).

On the reverse side of this card the physician should note the condition of the hearing, the eyesight and the teeth; defects in the palate; condition of the tonsils, question of adenoids, mouth breathing, condition of the nose, and of the glands of the neck; the shape of the chest and abdomen; any defects of the spine, legs and feet; and the condition of the lungs, heart and abdominal organs. If there is bed-wetting it should be recorded, and in such cases the condition of the prepuce noted by the physician, or the condition of the clitoris noted by the trained nurse. If there is suspicion of kidney disturbance the urine should be examined. If the child appears anemic the blood should be examined. A general statement of the state of health and nutrition, and the condition of the skin should be noted; also the medical opinion of the development of the child up to the present time. The disposition of the case should also be stated, that is, what advice was given. The card should be carefully dated. Subsequent examinations should be on a separate card, which should be clamped to the original.

The results of the foregoing examination should determine the proper treatment, if any treatment is needed, and should determine the instructions that should be given the parents as to the need of seeking the advice of their family physician or of consulting a specialist. Also, the outcome of this examination would disclose the need, or not, of special physical exercises to correct beginning deformities. All children deemed able should then be taught by a physical teacher the physical culture exercises deemed wise for children of this age; one hour a day of various exercises under instruction as classes, and another hour in the school playground. The physical teacher should devote two or more hours a day teaching and treating children with physical defects.

All of this requires money, but to what better object could public money be devoted than to building up the physique of our children and to prevent future defectives and future disease?

At 8 years of age the child is physically and mentally ready for regular school work (not too many hours, or too much home study, as previously cautioned). Such children on growing up keep the habit of exercise, thus acquired, to their benefit, as they will live in the age of labor-saving devices and work that requires but little muscular effort.

Bad home food and bad home and house hygiene would be corrected as far as possible by the visiting nurse, who can be the trained nurse attached to each large public school. Again, all this costs money and seems ideal, but such an outlay would pay the community good dividends on the investment by raising healthy citizens and in preventing disease. Some of this cost could be offset by not appointing so many teachers of things that are not essential and devoting more time to the groundwork of education.

To repeat, it should be urged to push only the essential studies, and curtail or cut out non-essentials and trimmings. Later, both boys and girls, but the latter especially, should be instructed in bacteriology and physiology and hygiene. Much valuable information may be given by the picture method of illustrating the causes of disease, etc.

It is not advised to pauperize the people by developing or using too many unneeded free dispensaries. *Let all parents, unless they are positively unable, take their defective children to physicians, surgeons and dentists of their own selection.* Of course provision must be made for those children whose parents cannot pay for such services; but let the visiting nurse make this decision.

As the children grow older they should be taught how to walk, and dancing exercises of the supervised type might be a part of the physical culture.

When the child is 8 years of age and begins the regular school work, its mental condition should be noted, unless it has been previously declared "feeble-minded." Those who are "feeble-minded" should be segregated and taught separately from the bright children, and an entirely different course and entirely different future plans of educational work should be outlined for such children, distinct from the regular course of instruction for the normal children.

It is an economic mistake not to separate mentally defective children from normal children. Three years ago it was estimated that there were three million children in the United States repeating a school grade a second, third, or even a fourth time at a cost of a hundred million dollars annually to the country, a needless and wasteful expense.[2] It is declared that the mental capacity of an idiot at any age does not exceed that of a child of 2 years; that of an imbecile of any age does not exceed that of a normal child of 8; and that of a feeble-minded person of any age may range from the normal mental capacity of a child from 8 to 13, but never exceeds the 13-year limit. These figures emphasize the necessity of the segregation of feeble-minded children, and also the crime of punishing for indifference or delinquency these children, who are doing all they can do.

The frequency of the physical examinations must, of course, depend on the findings in each case. Defective children should be examined, at least as to the condition of the defect first found, once in three, six or twelve months, depending on the kind of defect. The results, for instance in adenoid or anemic children, should be certified to by the trained nurse on the reverse side of the child's card; that is, whether or not operation has been done in the one case, or whether the child is improved or otherwise in the other case, the child, supposedly, being under the care of the family surgeon or physician.

All of this is paternalism, but only thus is the good of the greatest number accomplished, and no person should be allowed to cause himself to become a tax on the community, to spread disease, or to break well-known laws of health and hygiene.

As the child grows older, as suggested above, he should be taught general hygiene, the laws of contagion, and the ordinary methods of communicating each disease, and simple rules of prevention. Simple anatomy and simple physiology, and the simplest kind of life problems should be taught in public schools. Sex hygiene should not be taught to mixed classes or much in mixed schools. The girls, at or before maturing age, should be instructed in such hygiene individually, not in classes, by the trained nurse. The boys may be talked to by the principal of the school in small groups confidentially, not from the platform.

---

[2] Report of Committee on Medical Inspection of Schools, The Journal A. M. A., Nov. 25, 1911, p. 1753.

It is necessary to urge the foregoing physical examination because of the twenty million children attending public schools in the United States only about two-fifths have more or less efficient school inspection and only a very few have medical examinations, and the muscle strength and physical development of our people is said to be deteriorating.

It should be urged that good able physical instructors must be obtained, or serious mistakes are liable to be made. After 10 years of age it is very doubtful if the games and exercises played or taken by boys should be as strenuous for girls; but it has been shown by some careful observers that girls are not harmed by ordinary exercises while menstruating. In fact, it is a serious error for a girl or her mother to believe that she must be an invalid for one or two days every time she menstruates, and a young ladies' seminary that puts each girl to bed for a day at each menstrual epoch does a serious mental injury to the girls. On the other hand, it is not advisable to cause these growing, maturing girls to climb stairs all day in a schoolhouse.

Chronically nervous children, and certainly the epileptics, should be sent home until cured (if cure is possible), or given an entirely different kind of schooling, away from large numbers and the shame caused by the publicity of their defects. Open-window or outdoor schools with small numbers of pupils and individual teaching, and scientific medical psychopathic decision of the best management to overcome such nervous defects as stage fright, stammering, weeping, brain storms, etc., should be the course followed with such children. The regular teachers, underpaid and overworked, should not be made responsible for the instruction or welfare of these children.

The only treatment for developed chorea is rest in bed; if the case is not severe, open air treatment in the country or at the seashore is essential, best where it is warm, and where the child can be under the care of one well-balanced person. Books, and playing with other children should generally not be allowed. Parenthetically, it might be mentioned that rheumatic germs should be suspected, and all disease from tonsils, adenoids, teeth and gums eradicated.

Mental fatigue (with good judgment as to hours of confinement and study and of intermittent play and exercise periods) should rarely occur, except in the nervous or neuropathic or otherwise diseased child. Precociousness and the morbid desire to overstudy is a sign of mental unhealth, and such children should be restricted in their book work and be compelled to do more physical work. If such management is not successful, they should be treated as psychopathic and as nervous children.

It may be briefly suggested here that adenoids, which are so frequent in young children, tend to shrink by the age of 14 or 15; but the teacher may readily observe, without medical examination, that a child is a mouth breather, looks dull and stupid, that there is beginning deafness, that the speech is imperfect, and that the chest expansion is incomplete. Mouth breathing interferes with the growth of the face and nose.

About 1 per cent. of children have discharging ears, and such ears may carry infection. Hence both for the child's sake and for the sake of others a discharging ear should be treated by an expert.

Eye-strain is of frequent occurrence in children, and headaches, granular lids, twitching of the lid muscles, and disturbances due to imperfect eyesight should be ever watched for by the teacher. Much absence from school, much loss of appetite, much nervousness, and much inability to study properly and advance are due to eye defects, a large proportion of which may be corrected.

(To be continued)

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

BACILLUS PYOCYANEUS VACCINE (See N. N. R., 1914, p. 254).

E. R. Squibb and Sons, New York City.

Pyocyaneus Vaccine.—Marketed in boxes of 6 ampoules containing respectively, 100, 100, 500, 500, 1,000 and 1,000 million killed bacilli, with a syringe.

STREPTOCOCCUS VACCINE (See N. N. R., 1914, p. 257).

E. R. Squibb and Sons, New York City.

Streptococcus Vaccine.—Marketed in boxes of 6 ampoules containing respectively 100, 100, 500, 500, 1,000 and 1,000 million killed streptococci, with a syringe.

FRIABLE TABLETS OF EMETINE HYDROCHLORIDE, Mulford.—This dosage form of an accepted article has been accepted for inclusion with New and Nonofficial Remedies.

Each tablet contains emetine hydrochloride 0.032 Gm. Prepared by H. K. Mulford Co., Philadelphia.

ANTIRABIC VACCINE (See N. N. R., 1914, p. 269).

Pasteur Institute of St. Louis, St. Louis, Mo.

Antirabic Vaccine.—The virus is obtained from glycerinated brain substance. Marketed in 5 Cc. ampules. The treatment consists of eighteen doses which are sent by mail daily by special delivery, each dose being slightly larger than the preceding.

TYPHOID VACCINE (See N. N. R., 1914, p. 259).

H. M. Alexander and Co., Marietta, Pa.

Typhoid Vaccine, Immunizing.—Marketed in packages of three syringe containing respectively, 500, 1,000 and 1,000 million killed typhoid bacilli. Also marketed in packages of three ampules containing respectively 500, 1,000 and 1,000 million killed typhoid bacilli and in packages of ten sets of three ampules containing respectively, 500, 1,000 and 1,000 million killed typhoid bacilli.

RUBBER AS A SOURCE OF HYGIENIC DANGER

Every physician is necessarily interested in the chemistry of rubber because this is one of the materials which enter into numerous articles and devices daily applied in medical and surgical practice. Experience teaches the unlike qualities of different types or brands of rubber. Some of them retain their original elasticity for a long time under the imposed conditions of usage, while others speedily deteriorate into brittle and useless scrap despite the various precautions of preservation that are embodied in familiar directions. The economic aspect of the quality of rubber goods offered for sale to the medical profession is an important one, because the expenditures in this department of the physician's equipment as well as of the supplies for the sick room and hospital are not inconsiderable.

The time is arriving when the purchaser of rubber will demand some reliable information as to the quality of the product which he is paying for. Rare, indeed, is the person at the present time who has any idea whatever of the make-up of rubber. Pure india-rubber, or caoutchouc, in its natural state is entirely unsuited for commercial use. It is soft and sticky, and readily undergoes spontaneous oxidation to a hard, brittle resinous substance. By vulcanization, a process in which mixtures of the crude gum with sulphur, or metallic sulphids or oxids are heated, a rubber is formed which is more permanently elastic and less subject to spontaneous change. The simplest type of vulcanized rubber, such as would be obtained from a properly heated mixture of sulphur and pure gum, is quite soft and offers little resistance to ordinary rough usage. Rubber of tougher qualities, but with lower elastic limits, is produced by the addition of metallic oxids, such as those of lead and of zinc, to the other ingredients before vulcanization. Among other constituents added to give required characteristics are the various pigments which furnish the color, Venetian red (iron oxid), ultramarine, lampblack and various organic dyes being among the ingredients which are employed.

A recent government report[1] calls attention to the fact that a large number of additional materials are used in rubber compounding simply to reduce the cost of the product. Among these may be mentioned whiting (calcium carbonate), barytes (barium sulphate), clay and various rubber substitutes, such as artificial rubber, oils and tar products. Finally, so-called recovered rubber, or shoddy, is used to a large extent in rubber compounds, resulting in a varying and generally unknown composition of the mineral constituents of the finished product. It is further stated that antimony sulphid can replace the sulphur, wholly or in part, in a simple vulcanized rubber, the resulting product being a brilliantly colored terra-cotta rubber. As the metallic base also gives a certain toughness and durability to the product, the use of antimony sulphid in place of sulphur was formerly considered highly desirable in the production of a rubber having wearing qualities. Despite the fact that even better wearing qualities can now be obtained by the use of other metallic compounds, especially zinc oxid, red rubber is still popularly regarded as a superior product. This in turn has led to the artificial coloring of ordinary rubber by the use of other compounds, such as iron oxid and organic coloring matter, so that one may find on the market many varieties of red rubber that are free from antimony.

In the case of most articles of rubber the existence of filling materials, pigments, etc., has no hygienic import. Cost and durability are the chief concern of the purchaser. The use of various heavy metals in the manufacture of nursing-nipples and small rubber toys affords an instance of a possible unsuspected danger to the health of infants, who tend to extract soluble products from such articles in the mouth or by the gastric juice when small pieces of the rubber are accidentally swallowed. Obviously they should be free from soluble toxic substances.

The Public Health Service has lately published information respecting the general characteristics of rubber used in nipples and toys with special reference to the use of heavy metals and to the presence of residual acidity in the compound. All specimens examined contained both iron and aluminum in considerable quantities. This indicates a rather general use of clay as a filling material. In the red rubbers either zinc oxid or magnesia was used in addition, while in the black rubbers two samples contained zinc oxid and three samples contained barytes. Antimony was found in four cases out of seven among the black rubbers and in five cases out of eight among the red rubbers. The three remaining specimens of red rubber were colored with Venetian red. The white rubber toys contained clay and zinc oxid, and one of them contained barytes. No traces of arsenic, lead or mercury were found in any of the samples examined.

---

[1] *Phelps, E. B., and Stevenson, A. F.:* The Chemical Composition of Rubber Used in Nursing-Nipples and in Some Rubber Toys, *Hyg. Lab. Bull.* 96, U. S. P. H. S., 1914, p. 55.

The government chemists state that the occurrence of antimony in black rubber can be explained only on the hypothesis that rubber scrap or recovered rubber has been used in the compounding. We are told that the use of miscellaneous scrap, and especially of recovered rubber or shoddy, is objectionable because of its unknown chemical composition. The use of lead compounds in rubber preparations is common, and salts of mercury are used to some extent. Either of these metals would be highly objectionable in a compound to be used for nipples or children's toys.

A study of the solubility of the antimony found in rubber nipples—particularly of the red variety—was made under conditions approximating what might exist with infants. They showed an extraction of quantities of antimony of 20 per cent. of an emetic dose in normal saliva and of from 40 to 160 per cent. of an emetic dose in saliva of an acidity commonly found in an infant's mouth. It is apparent, therefore, without further discussion of the possibilities of a cumulative action of slight dosings resulting from the absorption of small amounts of antimony over a considerable period of time, that the use of antimony rubber in nursing-nipples, teething-rings and other rubber materials used by young infants is at least undesirable.

There are certain specifications which determine the general hygienic properties of rubber nipples in respect to ease of cleansing. With regard to the composition of these and other rubber articles which are given to young children the government report concludes: The articles should be made of a good grade of black rubber, free from shoddy and from antimony, lead, arsenic and mercury. Of the fillers commonly employed, magnesia, zinc oxid and clay are less undesirable, and barytes is probably without harmful influence. There can be no objection to a red rubber colored with iron oxid, although the advantages of such a compound will probably not compensate for the disadvantages of its being confused with antimony rubber.

CHANGES IN THE ADRENAL GLAND IN DISEASE

The large amount of discussion regarding the structure and function of the adrenal glands and the rôle they play in various diseases has given rise, on the whole, to conclusions which have been rather contradictory. According to Elliott,[1] the normal amount of epinephrin in the glands as estimated by various observers has been too low, owing either to faulty technic or to failure to take into account the rapid post-mortem loss of the substance. Usually this loss amounts to from 10 to 15 per cent. in eighteen hours, a considerable factor which must be taken into account in drawing conclusions from post-mortem material. The adrenal of a normal adult man should weigh from 4 to 5 gm. and should contain from 4 to 5 mg. of epinephrin. Conditions of fright, anesthesia, cerebral injury, bacterial intoxications, etc., have been found to exhaust the store of epinephrin in animals through the action of the splanchnic nerves, and it is fair to assume that these conditions probably produce a similar effect in man, so that any disease complicated with such conditions should show loss of epinephrin. In infectious diseases such as malignant endocarditis, pneumonia and all acute infections in general, the residual amount of epinephrin in the gland was found by Elliott to be considerably lessened, but apparently not enough in any case to endanger the circulation. The greatest loss was found in cases of afebrile, acute cardiac failure associated with great mental distress in the struggle for life. Simple cardiac failure without emotional disturbances, on the other hand, seems to produce very little loss of epinephrin.

The belief held by many that certain diseases with high blood-pressure are associated with hypertrophy of the medullary substance of the adrenal is not substantiated by Elliott. Obviously it would be difficult to measure the size of the medulla and the amount of epinephrin in the gland and circulation accurately enough to determine whether or not there is an increase in the amount of epinephrin. But if in a chronic case of high blood-pressure with renal disease, the patient dies from simple uremic intoxication without secondary infections and circulatory failure, without the adrenals being hypertrophied and without accumulation of epinephrin, we may then conclude that medullary hypertrophy is not a chief factor in the disease. In Elliott's work the glands examined in this condition did not show any enlargement which could not be ascribed to cortical adenoma or edema. In fact, there is no proof that the store of epinephrin is increased in any disease.

As a rule, changes in the medulla of the gland are slight if any; changes are common in the cortex, adenomatous growths of cortical substance being often found as, also, are changes in the amount of cortical lipoid. Under normal conditions the lipoid is stored in the form of doubly refractive granules, and when for any reason the cortical substance is diminished, the granules become smaller and finally disappear. These cortical lipoids are stored and lost under conditions entirely different from those which govern the other fats of the body. In persons dying from diseases with extreme emaciation, from starvation, such as is seen in anorexia nervosa or chronic tuberculosis without acute febrile reaction, in which the body fat is completely exhausted, there is little or no loss of cortical lipoids. In acute infections the cortical lipoids vanish rapidly. In Elliott's series of cases, pneumonia produced the most rapid and complete exhaustion. Scarlet fever, measles, malignant endocarditis and acute febrile tuberculosis also produced great loss [illegible] not so complete as pneumonia. In various septic infections the amount of loss depended on the severity of the infection, but was considerable in all cases. Diphtheria, being a disease of great toxicity and little febrile reaction, produced little loss of cortical fat. Also, a case of cerebral compression, in which there was a postoperative non-septic fever to 107 F. for long periods of time, resulted in no loss of cortical fat. On the other hand, chronic renal disease is often associated with cortical adenoma and hypertrophy. In this disease there is a tendency for cortical fats to appear in excess, especially in conjunction with arteriosclerosis. In these conditions, however, no definite relations can be said to exist, so that we cannot say that arteriosclerosis is caused by cortical hypertrophy. It is of importance, too, that according to Kolisko[2] constant changes are found in the adrenals in deaths from burns. There may be more or less extensive hemorrhagic infarction in acute cases, and when death occurs later, marked hyperemia with great reduction of lipoids. Possibly these changes stand in direct relation to the cause of death in burns, concerning which there are various views. It would be of interest to learn something in regard to the content of epinephrin in the adrenals in burns.

---

[1] Elliott, T. R.: Pathological Changes in the Adrenal Glands, Quar. Jour. Med., 1914, viii, No. 29.

The observations cited indicate the need of further work in the hope that the relationship of the structural and chemical changes in the adrenals in various morbid conditions to the general physiologic disturbances may be made clear.

THE PALPATION OF ARTERIES

By palpation, writes Osler in connection with the diagnosis of arteriosclerosis, we are enabled to judge with fair accuracy the degree of thickening of the vessel wall. It requires not only experience, but also education, to form a correct judgment on the state of the arteries. A perfectly normal vessel, when contracted, may feel hard and cord-like. On the other hand, in a radial definitely thickened, but in a state of extreme relaxation, the hardening of the walls may escape detection. The state of the tissues about the artery, the amount of fat in the skin, the size and fulness of the veins—all have to be considered. One of the commonest of mistakes is to regard as thickened any vessel one can roll under the finger. But in a state of very high tension and if very full, the arterial tube may feel cord-like. To estimate the presence of sclerosis it is not sufficient to examine the radials and temporals.[1]

It is as difficult at times, as it is important, to recognize the difference between the hard sensation conveyed to the finger by a high-tension pulse and that conveyed by stiffening of the arterial walls. The two may even coexist. If the palpation of the arteries is to reach the dignity of an accurate aid to diagnosis, it becomes necessary to be able to correlate the tactile impressions of the physician with the true anatomic and functional conditions of the vessels he is examining. A few competent investigators have actually compared the subjective impressions gained by palpation of the radial arteries with the structural conditions revealed in the same vessels on examination post mortem. The conclusions are far from concordant in respect to the sufficiency of the judgment of the respective observers. One group has gained the distinct impression that the palpability of the vessels actually depends on the relative thickening of the arterial wall, the thickening of the intima preponderating over the hypertrophy of the media. Another group of clinicians has reached an utterly skeptical conclusion. They have compared the histologic picture of the vessels examined with the recorded judgment of the clinician who previously examined them by palpation. Many of the arteries which felt at most only slightly rigid showed marked sclerosis of the intima; others, in turn, which exhibited pronounced rigidity on skilful palpation were free from significant histologic changes. There is no question as to the competence of the observers in these different cases; they rank among the leaders in American and European medicine. The impartial judge has inevitably been constrained to the tentative conclusion that the strength of the middle coat of the arteries and the varying conditions of tonus of the arterial musculature must be of some moment in the palpation of blood-vessels.

The skepticism awakened by careful investigations is, indeed, justified by a very careful study just published from Romberg's clinic in Munich and conducted under the guidance of Schlayer. This work of Landé[2]—a comparison of Romberg's judgment of the living subject with the actual anatomic finding after death—shows that in a very considerable number of cases of apparently rigid arteries the histologic picture furnishes no explanation for the estimated rigidity. These discrepancies, which may also involve the reverse situation of sclerotic vessels that go unrecognized by the touch of trained clinicians, are not merely occasional. At least half of the records collected in considerable number involved irreconcilable features. They lead to the conclusion that so simple a clinical fact as the rigidity of arteries is by no means correlated with equally simple anatomic and functional conditions of the vessels palpated.

In the actually sclerotic arteries, as Landé notes, the increase in rigidity is brought about by the alteration of the particular tissue portion which is most called into play functionally by the type of vessel concerned. In highly muscular arteries the smooth musculature of the media undergoes degenerative change; in the more elastic vessels it means the replacement of the more elastic fibers by less responsive connective tissue. Nevertheless, despite these unlikenesses in acquired pathologic structure, the palpable effect—the arterial rigidity—is essentially the same. For the other cases of rigidity, when an anatomic exhibition of typical sclerosis is lacking, the explanation is not easy. In some, such as the arteries associated with contracted kidneys, there may be an increase in the entire thickness or volume of the vessel wall; in still others, the cause of the palpation results is not evident. The comparison of post-mortem facts with ante-mortem clinical judgments has long been one of the best and surest ways of bringing progress into the field of diagnosis. We need more of it.

EMBOLISM AND THROMBOSIS OF THE MESENTERIC VESSELS

Occlusion of the mesenteric vessels is regarded generally as a very uncommon condition. It occurs often enough, however, to require consideration whenever obscure, acute abdominal lesions are subjected to thorough examination with a view to accurate diagnosis and proper treatment. That it is not in any sense an extremely rare disease is shown by the fact that recently Trotter[1] collected no less than 366 cases, seven being original, from the careful study of which he has been able to draw some valuable conclusions. It appears that the disease rarely affects children, adults between 30 and 70 years being most liable to be attacked, and men nearly twice as often as women. The occlusion may involve the arteries (53 per cent.), the veins (41 per cent.), or both together (about 6 per cent.). The superior mesenteric vessels appear to be involved much more frequently than the inferior. In 64 per cent. of the cases considered by Trotter, the result was hemorrhagic infarction of the intestine. Anemic infarction occurred in 2.7 per cent. When typical infarction was absent, extreme engorgement, ulceration or perforation were observed in the area corresponding to the occluded vessels. The most common cause of arterial occlusion appears to be embolism, originating in most cases from acute or chronic endocarditic changes, and less frequently from thrombi in the aorta or heart. Occasionally, however, occlusion results from thrombosis due to chronic, sclerotic changes in the mesenteric artery or in the aorta. Occlusion of the mesenteric vein is due to thrombosis, usually a downward extension of thrombosis in the portal vein, but occasionally arising in the mesenteric vein itself as a result of an inflammatory process in the appendix or in the pelvis in the case of women.

The most striking clinical manifestations of mesenteric occlusion are sudden onset, acute abdominal pain, vomiting and diarrhea, the stools and vomit not uncommonly containing blood, the stools sometimes a great deal. In some cases constipation is present. Usually shock is severe with rapid and irregular, small pulse and normal or subnormal temperature which soon rises above normal. The abdomen becomes distended. In a few cases the hemorrhage between the mesenteric layers has been felt as a swelling through the abdominal wall. Visible peristalsis is rare. In Trotter's series peritonitis was present in at least 28 per cent. of the cases. When large or medium-sized vessels are occluded, death practically always results in a few days unless operation is made at an early stage.

That the clinical diagnosis of mesenteric occlusion is difficult is indicated by the circumstance that in Trotter's series it appears to have been made in only thirteen cases. The presence of endocarditis and of embolic manifestations elsewhere are valuable guides to diagnosis in cases presenting acute colicky abdominal pain, profuse bloody diarrhea, or constipation, vomiting, abdominal distention and grave constitutional disturbances. One difficulty is that the clinical picture is extremely variable, often incomplete; but if the idea that mesenteric vascular occlusion is a very uncommon condition could be forgotten, so that the possibility of its being present would be considered when the diagnosis of an acute abdominal lesion is under discussion, it no doubt would be diagnosed oftener. The cases in which operation with resection has been made appear to give 36.2 per cent. of recoveries. It would seem that if operation were made as soon as possible after the onset of acute symptoms, better results would be obtained.

THE DISTRIBUTION OF IODIN

Although iodin and products containing it have long belonged to the armamentarium of medical practice, a unique interest in the element was aroused by the discovery by Baumann, in 1895, of its presence in the thyroid gland. There has been no lack of speculation as to the significance of this and the literature is full of conflicting statements as to the possible part that iodin may play in the animal economy. With the accumulation of reliable facts regarding the distribution of iodin in nature it seems more and more probable that its appearance in special tissues, notably the thyroid, in comparatively greater abundance than elsewhere, is not a mere accident.

Undoubtedly the true biologic significance of iodin will become more and more elucidated when our knowledge of its distribution in living forms has been extended far more widely than at present. To Dr. Cameron of the University of Manitoba at Winnipeg, we owe an important contribution involving many laborious estimations of iodin in all sorts of animal and plant tissues.[1] Facts thus collected are important in indicating not only the possible sources for the commercial preparation of the element, but also the sources from which it can find its way into the animal organism. It has long been known that iodin is present in almost all sea-weeds; indeed, it was discovered in kelp by Courtois in 1811. It now appears to be an invariable constituent of all marine algae in amounts greater than 0.001 per cent. Distinct variation of iodin content can occur in the same species, growing under almost the same conditions, and in different, but closely related species. No satisfactory cause has yet been assigned to explain such differences. The marked difference between fresh-water plants and the ordinary vegetables, on the one hand, and marine algae on the other is unquestionably due to difference in the iodin content of the environment, and therefore in the diet of these plants. The differences in different species growing under similar conditions, Cameron suggests, may be associated with a specific quantitative action of the plant in retaining iodin.

---

[1] Trotter, Leslie C. B.: Embolism and Thrombosis of the Mesenteric Vessels, Cambridge, 1913.

[1] Cameron, A. T.: Contributions to the Biochemistry of Iodin. I. The Distribution of Iodin in Plant and Animal Tissues, Jour. Biol. Chem., 1914, xviii, 335.

Iodin is present in appreciable quantities in certain tissues of all marine species. Cameron remarks that as we get higher in the scale there is more differentiation (and probably less total iodin in the whole organism) until in vertebrates, and particularly in mammals, thyroid tissue alone is of consequence in connection with the storage of the element. We are reminded that where there is a circulation of iodin in the organism, other tissues will also contain minute amounts; but the smallness of the figures obtained by Cameron and others indicates that the presence of iodin in such tissues is in all probability without significance. It is less than 0.001 per cent. in all non-thyroidal tissue.

Despite the marked variations of iodin content in thyroid tissue even in individuals of the same species —variations traceable to differences in diet—the element is an invariable constituent of normal tissue of this gland. The minimal quantity appears, according to Cameron, to be about 0.01 per cent., the maximal quantity approximating 1.16 per cent. Under normal conditions the diet always contains sufficient iodin for the upkeep of a minimal amount.

Natural Selection and Functional Selection.—Of course natural selection plays its part, as it must in all cases, even in the inorganic world, and I believe that in many cases, as for example in protective resemblance and mimicry, that part has been an extremely important one. But much more important than natural selection appears to me what Baldwin has termed "Functional Selection," selection by the organism itself, out of a number of possible reactions, of just those that are required to meet any emergency. As Baldwin puts it, "It is the organism which secures from all its overproduced movements those which are adaptive and beneficial." Natural selection is here replaced by intelligent selection, for I think we must agree with Jennings that we cannot make a distinction between the higher and the lower organisms in this respect, and that all purposive reactions, or adjustments, are essentially intelligent.—Arthur Dendy, *Medical Journal of Australia.*

Current Comment

SINGEING THE HAIR

The reams of paper that are used up each month in articles in the daily papers — and weekly and monthly papers — on beauty culture is conclusive evidence that it is as natural for man to desire to beautify the person as it is "to indulge in the illusions of hope." A sound mind in a sound body suffices the serious-minded minority, but apparently the innumerable majority, if they had their way, would have a comely body and take their chances on any old kind of a mind, on the principle that it is better to be good looking than wise, because more people have sight than understanding. To decorate and beautify the body is an inborn passion; the savage does it differently from us, but when it comes to the many manipulations and remedies that are recommended for avoiding wrinkles, giving the eyebrows an aristocratic arch, coaxing the lashes to be long and languorous, making the ears pink and small or the nose straight and thin, removing a double chin or taking the core out of the Adam's apple, we have nothing on our uncivilized and supposedly more ignorant brothers. The hair in particular is the object of all mankind's cosmetic endeavors. When it comes to civilized man he is universally engaged in trying to save what he has left or regrow what he has lost. Women, with few exceptions, do not become bald, but all women, in their opinions, are threatened with that unspeakable calamity; men not only may get bald, but a large number of them are already so. And thus the popular remedies for the hair need almost a Surgeon-General's catalog. Vibratory and electrical treatments, hair tonics that feed the hair roots, as though they grew out of the scalp like broom-sedge out of an old field, neat's-foot oil and crude kerosene, massage and mange cures, all have their futile trials. Among these our particular topic now is singeing the hair. This is recommended to overcome splitting at the ends and to prevent falling of the hair, the reason for the latter being that it "closes the pores and keeps the fluid in the hair." With the long hair of a woman which has a tendency to split at the ends, it is possible that singeing the tips may be of some use; it substitutes a charred blunt end of fused horn for one tapering to a point or cut clean across. But even in cases of this sort it is less useful than greasing lightly the hair and thus supplying the fat which is lacking in such hair. For the hair of men, which is kept short, singeing is not of any use in preventing splitting; hair which is not allowed to grow to its natural length does not split, unless it has a deep-seated disturbance for which there is no such simple remedy. Of course singeing the hair-ends in order to prevent the fluid in the hair from escaping, like sap from a tree, is based on an entire misconception of the hair's structure and nutrition. The hair does not contain any more sap than a buggy whip; it is not nourished by any fluid in it, but by the blood plasma that reaches only the hair root. The hair above the skin surface is a spine of horn, which is even oiled from without, and singeing its tips has no effect whatever on either its nourishment or its growth. It is certain that singeing the hair is of no value in preventing its fall; in fact the only value the procedure has is to the zealous hairdresser who gets his little fee for doing it — unless it is worth a quarter to the seeker after hair to think he is doing something, even if he is not.

CHLORIN-BLEACHED FLOUR

Since the bleaching of flour with the oxids of nitrogen has been forbidden in the United States under the Food and Drugs Act, there are signs of the introduction of other processes intended to produce similar changes in the wheat product. In one of these chlorin is the bleaching agent employed, the anhydrous gas being diluted with an inert gas and then used to "mature and whiten" the flour. Without commenting at this time on the legal aspects of the matter, we may fairly ask whether the new process confers any advantages on the cereal which will render it superior to the ordinary unbleached patent flour. Mere appearance need not be taken into consideration here. Experiments conducted in connection with the pure food work at the Kansas State Agricultural College[1] in Manhattan have shown that although the chlorin content of untreated flour may run as high as 576 parts per million, chlorin-treated flour will contain over 600 parts per million. Chlorin-treatment increases the acidity of the flour. The gluten tests run practically alike for the bleached and unbleached flour. The baking experts report that there are no differences in loaf volume; but the bleached flour gives a loaf having an objectionable color and texture. In nearly every case the bread made from the unbleached flour graded better. Evidently the chlorin-bleaching cannot be defended on the ground that bread-making qualities of the flour are improved.

GAME, STOCK AND CITIZENS

The epidemic of foot-and-mouth disease and its effect on the packing industry and the stock yards of Chicago have been commented on widely in the daily press from various points of view. One of the most illuminating comments appears in a recent issue of the Chicago *Journal* under the heading "Live Stock Versus Quail." Taking the best available estimates of the amount of live stock contained in the state and figuring on an average value of horses at $140 a head, milk cows at $65, other cows at $50, swine at $15, sheep at $6 and mules at $150 (minimum valuations, as most will admit), the *Journal* says the total value of live stock in Illinois would be $435,276,000, for the protection of which the state legislature appropriated for the current year a total of $37,340. By way of comparison, the *Journal* quotes the appropriation for the protection of fish and game for the same time, which amounts to $151,600. The *Journal* properly characterizes such a situation as "intolerable." It says, "To spend four times as much money protecting quail, ducks and prairie chickens as we spend in caring for one of the basic industries of the state is sheer communal lunacy." This is true. The farmers and business men of Illinois should see to it that every cent that is necessary to protect the live stock of the state is provided, no matter what economies may be necessary in other directions. But, if such appropriations are justified for the protection of the lives and health of animals, how much should be appropriated to protect the lives and health of the men, women and children of the state? Certainly more than for fish, game and live stock. Yet the appropriation for the protection of the 5,638,591 men, women and children in the state was for 1914 only $120,000, $30,000 less than was appropriated for the protection of fish and game. Are the lives of its citizens of less value to Illinois than the preservation of its quail and bass?

VENOUS BLOOD-PRESSURE

Until quite recently it has been generally assumed that venous blood-pressure passively responds to changes in the peripheral resistance within the circulation and that it rises and falls inversely to the pressure in the arteries. There is now a growing belief, supported in part by experiments on both animals and man, that the pressure in the venous system may be dominated by a special nervous mechanism. We cannot review the entire story of this chapter of the physiology of the circulation which is still far from being presented in its final form. One apparent earlier obstacle to the hypothesis of a "venomotor" nervous mechanism has been in part met by the now well-established demonstration that the venous system is actually supplied with motor nerves. Only recently it has been shown that the veins may respond to epinephrin with constriction,[1] thereby furnishing one of the evidences nowadays accepted as indicative of sympathetic innervation. As a physiologist has expressed it,[2] although the evidence available at present is insufficient to establish definitely the existence of a venomotor system comparable to the vasomotor system proper, none of the evidence is against such a hypothetic nervous mechanism, and much of the data is impossible of explanation without such an assumption. It remains a fact, however, that no direct experimental proof has as yet been put forth. In distinction from the assumption that under normal conditions of life the peripheral resistance alone controls the magnitude of the venous pressure, Yandell Henderson has put forth the hypothesis that there is a venopressor mechanism which functions to maintain an optimum feeding pressure to the heart. This forms a part of his theory respecting the maintenance of the volume output of the heart.[3] The newest researches of Hooker,[2] at the Johns Hopkins Medical School, on the venous blood-pressure in man are in harmony with the existence of the hypothetic venomotor mechanism. He finds that normal venous pressure is independent of changes in peripheral arterial resistance. The capacity of a vein may vary without affecting the internal pressure. According to Hooker, the venous pressure in man exhibits a distinct diurnal rhythm, rising throughout the day from 10 cm. to 20 cm. and falling again during the night. The normal venous pressure varies very considerably, averaging in the day time and under usual conditions about 15 cm. of water; in sleep, at night, it may fall to 7 or 8 cm. The study of venous pressure in man has been comparatively neglected in the past. With a renewal of interest in its problems we may look forward to some valuable contributions to the knowledge of the circulation.

THE COST OF TUBERCULOSIS AND TYPHOID

Estimates regarding the loss caused by preventable diseases are always interesting, although necessarily general. The smaller the area affected, the more accurate are the figures apt to be. Prof. Irving Fisher's estimate, in his report on national vitality, of the economic loss for the entire country at one and one-half billions a year is familiar to students of public health conditions. An estimate recently issued by the Minnesota State Board of Health shows the economic loss from death from typhoid fever in Minnesota in the last six years to be $21,958,940, while the deaths from tuberculosis are six times as great and the loss three times as great as that from typhoid, or $66,583,320, making a total loss from the two diseases alone of $88,542,260 for six years, or an annual loss of $14,757,043. In making this estimate the following economic values were used in computing the financial loss from deaths: professional business men and farmers, $500; skilled laborers, $300; unskilled laborers and domestics, $200; married women, $200; children under 15 years of age, $100. These valuations are conservative and should represent the minimum rather than the maximum loss.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest; such as relate to society activities, new hospitals, education, public health, etc.)

ARKANSAS

Change in State Hospital Head.—Dr. James L. Greene has resigned as superintendent of the State Hospital for Nervous Diseases, Little Rock, and has been succeeded by Dr. Frank B. Young, Springdale, secretary of the State Board of Health, who will take charge of the institution November 30.

Free Clinic Established.—The first of the semi-weekly series of clinical lectures and examinations was held October 23, in the laboratory of the University of Arkansas, Little Rock. The clinic is maintained by the Pulaski County Anti-Tuberculosis Society. On Tuesday morning, white patients will be seen and on Friday morning negro patients will receive care.

Hospital Opened.—The Leo N. Levi Memorial Hospital, Hot Springs, made possible by the generosity of the late Leo N. Levi, was opened for the inspection of the public, November 1. The medical board of the institution is composed of Dr. William V. Laws, chairman; Dr. William H. Deaderick, secretary; and Drs. James C. Minor, Orvis E. Biggs and Samuel D. Weil.

New Medical Society Organized.—The South Nevada Medical Society composed of physicians residing in the southern portion of the county and the Nevada County Medical Society whose membership is made up of physicians residing in the northern portion of the county, met in Prescott, October 20, and perfected an organization to be known as the Nevada County Medical Society.——Dr. Thomas J. Mendenhall, Rosston, was elected president and Dr. William M. Garner, Bodcaw, secretary.

CONNECTICUT

Personal.—Dr. Harry St. John Williams has resigned as assistant superintendent of the Undercliffe Sanatorium, Meriden, to become superintendent of the Samuel L. Towne Memorial Hospital, Poughkeepsie, N. Y. Dr. Williams has been succeeded by Dr. Edward J. Degman, Southington.

The Brady Laboratory.—Plans are practically completed for the construction of the Anthony N. Brady Memorial Laboratory of the Yale Medical School. The laboratory and administration building will be erected early in the spring of 1915. The plans call for a three-story and basement building.

Tuberculosis Commissioner Appreciated.—The Bridgeport Employees Tuberculosis Relief Association of Bridgeport has presented John F. Gunshanan, Hartford, former tuberculosis commissioner of Connecticut, with a set of handsomely engrossed resolutions appropriately framed and setting forth the appreciation of the services of Mr. Gunshanan to the organization.

FLORIDA

New Board Member.—Dr. James Burnie Griffin, St. Augustine, has been appointed a member of the State Board of Homeopathic Medical Examiners, succeeding the late Dr. Henry R. Stout, Jacksonville.

Open Meeting of Medical Society.—On November 24, the Escambia County Medical Society held a public session at which the subjects for discussion were bubonic plague, mosquitoes, uses of the state laboratory, tuberculosis, medical inspection in schools and the cancer problem.

ILLINOIS

Personal.—Dr. Pierce Tyrrell, the oldest practitioner of Elgin, is reported to be critically ill.——Dr. George D. Hauberg, Moline, has been appointed official deputy coroner of Rock Island County.

New Tuberculosis Hospital.—A hospital to be used exclusively for tuberculosis patients is to be erected at Collinsville by Dr. Moses W. Harrison, who now conducts a private hospital and tuberculosis colony at that place.——The city commission of Danville has inspected a 2½-acre tract at that place with the view to its purchase as a site for its municipal tuberculosis sanatorium.

Proposed Buildings for Epileptic Colony.—Plans for the buildings for the State Colony for Epileptics, Dixon, have been prepared and bids for their construction have been asked for. The buildings consist of an administration building with three wings; dining halls and a service kitchen and a dormitory building to accommodate 52 persons. The dormitory cottages are to be built in groups of four around the main buildings.

Chicago

Red Cross Christmas Seals.—The sale of Red Cross seals opens in Chicago at stores, theaters, public buildings, etc., Monday, November 30. Each seal costs one cent. Remittances may be sent direct to the Chicago Tuberculosis Institute, Room 1212, Hartford Building, 8 South Dearborn Street.

Chicago Hall of Fame.—*A hall of fame* to commemorate the achievements of the citizens of Chicago is proposed as an adjunct to the sunken gardens which the city will place in Grant Park. The request of the Chicago Medical Society for permission to erect a $25,000 memorial to Dr. Nicholas Senn is believed to have led to this suggestion.

Health Department to Open School.—The Chicago School of Sanitary Instruction is soon to be opened by the health department. A course of instruction will be given to superintendents of milk plants consisting of lectures and demonstrations on the general principles of milk hygiene. All new employees of the health department will be obliged to take a six months' course of training. Students of medical schools in Chicago will be given instructions in public health work during the winter. In connection with the school the health department will supply speakers on health work to clubs and other organizations.

INDIANA

New Dispensary.—A free medical dispensary was opened at the Campbell Settlement House, Gary, November 16. The dispensary is open each afternoon from 1 to 2 o'clock.

Fatal Epidemic Among Rabbits.—A disease said to have caused the death of thousands of rabbits near Vevay, Switzerland County, is being investigated by the chief food inspector of Cincinnati. It is said that many shipments of rabbits have been made to the markets of Cincinnati and other cities since the outbreak of the epidemic.

Legal Question Delays Bond Issue.—An agreement by the Marion County Council, November 12, to authorize a bond issue of $80,000, the proceeds to be applied to a new county tuberculosis sanatorium, has been deferred on account of a legal question as to the date on which the council which has had charge of the appropriations and bond authorization, was succeeded by the new city council.

Personal.—Dr. John W. Sluss, superintendent of the Indianapolis City Hospital, has resigned and has been succeeded by Dr. Thomas L. Sullivan, Jr.——Dr. Raymond H. Stinger, Broad Ripple, has been appointed a member of the staff of the Southeastern Hospital for the Insane, Madison.——Dr. A. Golding Chittick, Frankfort, has been recommissioned as Captain, M. C., Ind., N. G., and reassigned to the command of Field Hospital No. 1, Frankfort.——Dr. Richard A. Poole, Indianapolis, has been elected coroner of Marion County.——The office and residence of Dr. Edwin L. Sigmon, New Albany, was destroyed by fire, November 6.——A reception was given by Dr. Anna I. McKamy, New Albany, November 5, to the members of the Floyd County Medical Association in celebration of the opening of her new hospital for women.

IOWA

Trichina.—An appeal to the State Board of Health for aid has been made from New Liberty, Scott County, where thirty-five cases of trichina are reported.

Publication Office Changed.—The publication office of the *Iowa Medical Journal*, the official organ of the Iowa State Medical Society, is to be changed from Washington to Des Moines. Dr. David S. Fairchild, Clinton, is editor of the journal.

Health Exhibit Opened.—Dr. Guilford H. Sumner, secretary of the State Board of Health of Des Moines, opened the state health exhibit in that city, November 5. The exhibit includes the material which was secured and exhibited at the state fair in August. A lecture is delivered each evening by Prof. A. E. Kepford, state lecturer on tuberculosis.

LOUISIANA

Pediatrician Wins Suit.—In a recent suit tried at Shreveport, in which Dr. C. Pearl Munday claimed a fee of $1,000 for medical service rendered as a pediatrician to two infants and in which a counter charge of malpractice was made, the jury returned a verdict in favor of the physician for $665 and costs.

Personal.—Dr. Charles C. Bass, New Orleans, winner of the Southern Medical Association medal for scientific research, was awarded the medal for a third time at the annual meeting in Richmond, Va., November 12.——Dr. J. George Dempsey, New Orleans, has been nominated for president and Dr. George F. Patton, New Orleans, for secretary of the Louisiana Anti-Tuberculosis League.

MARYLAND

Personal.—Dr. Robert P. Bay, Baltimore, has been appointed chief medical examiner of the state industrial accident commission. To date 353 accidents have been reported to the commission since the workmen's compensation law went into effect on November 1.——Dr. Clapham P. King, Annapolis, has sailed with a Red Cross unit on the steamer *Finland* for duty in Servia.

Baltimore

Portrait Presented to Faculty.—A life-size protrait of Dr. Samuel Claggett Chew, dean of Baltimore physicians, former president of the Medical and Chirurgical Faculty of Maryland, member of the board of regents of the Maryland University for more than forty years, and one of the best known medical men in the country, was presented to the faculty November 19, by the medical profession of Maryland. The presentation was made by Dr. Charles W. Mitchell, who spoke of Dr. Chew, the teacher, and Dr. William S. Thayer, who told of Dr. Chew, the physician. Dr. Randolph Winslow, president of the faculty, accepted the portrait.

Health Work at Stake.—A cut of $135,000 has already been made in Dr. Nathan R. Gorter's estimate to the Board of Estimates for the annual appropriation for the City Health Department. The board eliminated $50,000 for a modern hospital building at Quarantine and $85,000 for improvements the Commissioner of Health considered necessary at Sydenham, the municipal hospital for minor infectious diseases. That the department may be put on a more effective basis next year, Dr. Gorter has asked for twenty-five additional employees, increasing his salary account by $9,250. He has also asked for an increase of $10,680 in his expense account. These items have not been passed on definitely by the Board of Estimates, but the statement is made at the city hall that they will probably be reduced.

Applicants Turned Away.—The number of applicants for admission to Johns Hopkins University Medical Department was much larger at the beginning of the present session than previously. More students were turned away than were accepted—not on account of their lack of technical entrance qualifications, but because of a lack of room. The enrolment of students is limited to ninety in each class.——In order that the best qualified students may be chosen, no applicants for admission are accepted after July 1 of each year, and all selections are made between that date and July 15. In this selection the college officials are guided by (a) the student's grades in the scientific branches at college; (b) a personal letter from one of the science teachers, setting forth the student's fitness to study medicine; and (c) the general character of the institution in which the student obtained his preliminary collegiate training.

MICHIGAN

Sanatorium Notes.—The opening exercises of the new Anna T. Dodge Children's Building of the Municipal Sanatorium, Detroit, will be held October 28 and 29, simultaneously with the celebration of tuberculosis day.——The State Sanatorium, Howell, will ask the legislature for an appropriation of $55,000 for maintenance during the next biennium; $15,000 for an infirmary and $12,000 for a children's pavilion. During the last year 376 patients were admitted for treatment and in more than 75 per cent. improvement took place.——The committee on ways and means of the Wayne County Sanatorium, Eloise, has voted to build an addition to the institution to cost $130,000.——At the annual meeting of the Michigan Association for the Prevention and Relief of Tuberculosis, at Muskegon last month, Dr. Arthur F. Fischer, Hancock, was elected president; Miss Carol F. Walton, Ann Arbor, secretary, and Dr. Henry J. Hartz, Detroit, treasurer; Drs. Walter H. Sawyer, Hillsdale; John H. Kellogg, Battle Creek; Edward T. Abrams, Hancock; Robert B. Harkness, Houghton, and Aldred S. Warthin, Ann Arbor, were elected directors, and Drs. Herman Ostrander, Kalamazoo; Collins H. Johnston, Grand Rapids; Victor C. Vaughan, Ann Arbor, and John H. Kellogg, Battle Creek, were elected medical members of the executive committee.

MINNESOTA

Sanatorium Notes.—Blue Earth County has voted to build a tuberculosis sanatorium.——Lac Qui Parle County has voted to join with Yellow Medicine, Chippewa and Renville counties to build a joint sanatorium.——Grant and Poke counties have voted to unite with Stevens and Douglas counties to build a sanatorium.——About thirty-five counties in the state will build sanatoriums within the next year.

County Tuberculosis Sanatoriums Authorized.—At the general election, November 3, four counties, Grant, Douglas, Lac Qui Parle and Blue Earth, voted to establish county tuberculosis sanatoriums. The legislature will be asked to make appropriations, in accordance with the county sanatorium law, for half the cost of construction and half the maintenance of patients unable to pay. There are now thirty-five counties which have taken action for county tuberculosis sanatoriums.

Health Week.—The program of the Minnesota Public Health Association for Health Week beginning with Tuberculosis Sunday, November 29, is as follows: Tuberculosis Sunday, November 29, with the suggestion that sermons on tuberculosis be preached in all churches, with union services to be held wherever they can be arranged and addresses be made by physicians or tuberculosis specialists wherever possible. The collections should go to local church or community antituberculosis work.——Measles Monday, November 30, to show the prevalence of measles, schoolchildren are asked to form "M's" and "O's" about 3 inches square, the "M" to be worn by those who have had measles and the "O" by those who have escaped.——Typhoid Tuesday, December 1, is to be devoted to the investigation of the water supply.——Whooping-Cough Wednesday, December 2, is to be devoted to showing the prevalence of whooping-cough. All schoolchildren who have had the whooping-cough will wear a "W" badge and all who have escaped an "O" badge. ——Children's Thursday, December 3, should be devoted by all mothers and fathers to a consideration of the sanitary condition of the dairies from which their milk is obtained. ——Fly-Day Friday, December 4, should be devoted to render houses and outhouses fly proof.——The week closes with Seal Day Saturday, December 5, and an especial effort is to be made on this day to sell Red Cross Christmas Seals.

NEW YORK

County Sanatorium Approved.—A proposition for a county tuberculosis sanatorium for Lewis County was carried at the November election by a majority of 700.

Jamestown Tests Milk Supply.—The secretary of the board of health of Jamestown has secured the equipment for a municipal bacteriological laboratory to meet the requirements of the new sanitary code.

Society Honors Its Dead.—The Albany County Medical Society held its annual memorial service October 30, in honor of the deceased members of the last year, Drs. Charles H. Smith, Daniel V. O'Leary and John V. Hennessy. Appropriate resolutions were adopted and fitting addresses were made by several members of the society.

County Tuberculosis Hospitals.—At the recent election three additional counties, Chenango, Lewis and Suffolk, voted to establish tuberculosis hospitals. There are now twenty-nine counties in the state which either have or have planned for such hospitals. It is also reported that Nassau County, L. I., finds that the vote in favor of a tuberculosis hospital near Hempstead, L. I., must stand in spite of the objections of residents in that neighborhood.

Alarming Spread of Foot-and-Mouth Disease.—While it is reported from Albany that the epidemic of foot-and-mouth disease through the upper part of the state is well under control, the state department of agriculture is alarmed over the spread of the disease on Long Island. The epidemic has attacked four additional herds of dairy cattle aggregating 733 milch cows. The state department of agriculture has appealed to the federal bureau of agriculture for additional help and a special appropriation will have to be made by the state to meet the emergency.

Reduction of Summer Infant Death-Rate Through the Establishment of Infant Welfare Stations.—The New York State Department of Health announces that the infant death-rate during the past summer, for the city of New York, fell to 100 (as against 112 in 1913) and for the rest of the state exclusive of the city, to 119 (as against 143 last year). The department attributes part of the reduction to the mild summer but remarks that it is probable that much of the improvement is due to the infant welfare exhibits and stations which were established during the past summer.

New York City

Milk Pasteurization Ordered.—The health department issued an order on November 13, that all milk hereafter sold in New York City must be pasteurized. The order is based principally on the epidemic of foot-and-mouth disease.

Dr. Byrne Still Lives.—In The Journal of September 19, the notice of the death of Dr. Joseph Henry Byrne, New York City, appeared. This report was published on information given by our local correspondent for New York City. Under date of November 13, Dr. Byrne writes us that he is "very much alive and capable of kicking strenuously," at which we, together with Dr. Byrne's many friends, rejoice.

Personal.—Dr. Haven Emerson, sanitary superintendent, and Dr. William H. Park, general director of laboratories in the New York Health Department, have received a raise of salary from $5,000 to $6,000 a year on the condition that they give their full time to the work, relinquishing their private practice and their college work in Columbia University.

Montefiore Home Report.—The annual meeting of the directors of the Montefiore Home and Hospital for Chronic Diseases was held November 8, when a gift of $25,000 was announced. The income of this fund is to be used for juvenile patients. During the past year the institution cared for 630 patients at a cost of $265,050 and there was a deficiency of $15,000.

Academy Celebrates Anniversary.—The anniversary meeting of the New York Academy of Medicine was held on the evening of November 19. Hon. George McAneny, president of the board of aldermen, made the address. It being the custom of the academy to emphasize its interest in public welfare on these occasions the speaker chose as his subject, "Some of the Relations of the Profession of Medicine to Municipal Government." The meeting was followed by a reception and a collation.

Two Red Cross Units for Servia.—Two more Red Cross units sailed on the *Finland*, November 21, for services in Servia. The directors of the units are Dr. Ethan Flagg Butler and Dr. Ernest P. Magruder of Washington, D. C. The staff physicians are Drs. James F. Donnelly, S. H. Dodge, Knoxville, Tenn.; Clapham P. King, Annapolis, and Morton Lane. The company will land at the Piraeus and proceed at once to Nish via Salonika. They carry 75 tons of material for dressings and other stores.

Experiment in Physical Examination of Schoolchildren.—In accordance with a suggestion made by the committee on hygiene of the board of education an experiment is being made in the private examination of schoolchildren. Two districts have been selected and the parents given the opportunity to have their children examined by their own physician before entering school for the first time. If it is found that such examinations are made in any considerable numbers the medical inspectors will employ the additional time thus saved to the examination of children in the upper grades, and if the experiment should prove a success, the system will be extended.

Attempt to Solve the Ventilation Problem.—Arrangements have been made for a series of scientific tests on sixty or more Bronx schoolchildren with the object in view of solving the problem of ventilation in the schools. These experiments are to be conducted by the State Commission on Ventilation, of which Prof. C. E. A. Winslow is chairman. Preliminary experiments have been under way for the past nine months at City College. The new school building in which these experiments are to be conducted has two schoolrooms fitted up with every conceivable ventilating appliance, and having double ceilings, walls and floors in order to provide inlets and outlets for air at any point. There are seats for about thirty children in each room. While the commission has not yet made its official report, it is understood that it has reached some conclusions that apparently upset some fresh-air theories of long standing.

NORTH CAROLINA

New Hospital Opened.—The Winston-Salem City Hospital was opened for visitors November 4, by a reception at which the building was formally presented to the city and accepted by the mayor. The institution represents an investment of more than $100,000. On November 11 the hospital was opened to receive patients.

Sanatorium Wins Suit.—At Charlotte on November 6, the jury in the superior court, in an accident for damages brought by a woman against the Charlotte Sanitarium on account of the occurrence of nephritis said to have been due to a careless administration of ether at a minor operation six years before, rendered a verdict in favor of the sanatorium.

Personal.—Dr. James N. Gill, Weaverville, has recovered from injuries received in an automobile accident near Asheville early this month.——The residence of Dr. L. S. Blade, Elizabeth City, was damaged by fire November 6.——Dr. Robert H. Bradford, Burgaw, who was operated on for appendicitis at the James Walker Memorial Hospital, Wilmington, is reported to be convalescent.

County Sanatorium Wanted.—An appeal has been made to the commissioners of Guilford County, Greensboro, November 4, to provide a hospital for incipient tuberculosis. The commissioners appointed a committee composed of representatives from the County Health Board and the County Medical Society to look over the situation and recommend what course should be adopted.

State Hospital Vindication.—The supreme court of the state has handed down a decision confirming the judgment of the lower courts in the case of Salisbury vs. The Hospital for the Insane, Raleigh. The evidence shows that a former governor had appointed the plaintiff in the action, a director of the State Hospital by an interim appointment and at the meeting of the legislature the next governor designated another individual to fill the vacancy for which the appointment had been made, but not confirmed by the Senate. The court sustained the appointment of the official director, taking the position that the governor, at the time of the initial appointment, could nominate only for an interval term pending the session of the Senate which would confirm or refuse to confirm the appointment.

OHIO

Union Meeting of District Societies.—At the union meeting of the First and Second Councilor Districts Medical Society held in Dayton, clinics were held at St. Elizabeth, Miami Valley and the Dayton State hospitals. Eminent specialists from Chicago, Cincinnati and Indianapolis conducted the clinics.

State Health Board Member Dead.—Mr. Josiah L. Hartzell, the oldest member of the State Board of Health, who was made a member in 1893, and was twice its president; one of the earliest advocates of modern sanitation in Ohio; formerly editor of *The Repository*; a member of the American Public Health Association, and one of the trustees of the Ohio Historical and Archeological Society; died at his home in Columbus, November 11, aged 81.

Personal.—Physicians of VanWert County attended a banquet in VanWert, November 12, in honor of Dr. J. Arthur Hines who celebrated his seventy-second birthday anniversary and the fiftieth anniversary of his initiation into practice. Dr. Hines was presented with a gold headed cane suitably engraved.——Dr. Louis L. Syman, Springfield, has been reelected superintendent of the medical department of the Detroit, Toledo and Ironton Railway.

OKLAHOMA

Insane Patients Transferred.—The State Insane Asylum at Norman recently transferred 250 inmates to the new State Hospital at Vinita. More than 800 patients still remain at Norman.

Foot-and-Mouth Disease.—Dr. John C. Mahr, Shawnee, state commissioner of health, has issued a warning regarding the possibility of the spread of foot-and-mouth disease to human beings.

Free Pasteur Treatment.—The state health commissioner, John C. Mahr, Shawnee, announces that he is prepared to furnish free, from health officers or physicians of the state, the Pasteur treatment for hydrophobia to all who are unable to pay for the treatment.

Personal.—Dr. James A. Young, Oklahoma, who fractured his leg recently, is reported to be convalescent.——The house of Dr. John H. Baldwin, Calera, was destroyed by fire recently.——Dr. Harry E. Breese, Henryetta, who has been ill with malaria and complications, has recovered.——Dr. James A. Rutledge, Woodville, recently fractured his leg while playing foot-ball.——Dr. Herman E. Yazel, Oklahoma City, has sailed for Europe in the Red Cross service.

TEXAS

New Texas Surgical Organization.—At the annual meeting of the Medical Association of the Southwest at Galveston recently a new society to be known as the Texas Surgical Association, was organized. The members of the executive committee are Drs. Joseph H. Reuss, Cuero; John T. Moore, Houston; John B. Smoot, Dallas; Frank Paschal, San Antonio; William B. Thorning, Houston; Joseph D. Becton, Greenville, and James E. Thompson, Galveston.

Report of State Hookworm Commission.—Dr. Morris H. Boerner, Austin, assistant state health officer and director of the state hookworm commission, in his quarterly report says that the field work during July, August and September in Burleson, Milan, Bell, Anderson and Nacogdoches counties covered over 4,800 square miles and reached directly and indirectly more than 100,000 persons. Over 6,000 persons were examined for hookworm of whom 1,225, or 19 per cent., were found to be infected and given free treatment. The disease was found to be much more prevalent among children than among adults. Over 3,000 children were examined and 960, or 31 per cent., were found infected.

GENERAL

Canal Zone Physician Resigns.—Dr. Walter G. F. Baetz has resigned as a member of the medical staff of the Ancon Hospital, Canal Zone, and will practice in New York City.

Life Insurance Medical Directors to Meet.—The semiannual meeting of the medical section of the American Life Convention will be held at French Lick Springs, Ind., March 3-5, 1915. Dr. Frank W. Foxworthy is chairman of the program committee.

Southern Surgeons and Gynecologists to Meet.—The twenty-seventh annual meeting of the Southern Surgical and Gynecological Association will be held in Asheville, N. C., December 15 to 17, with headquarters at Grove Park Inn. Dr. John Wesley Long, Greensboro, is president of the association.

Southern Medical Women Elect Officers.—The second annual session of the Association of Medical Women was held in Richmond, Va., November 10, and the following officers were elected: president, Dr. Mary E. Lapham, Highlands, N. C.; vice-president, Dr. Mary A. Parsons, Washington, D. C.; secretary, Dr. L. Rosa H. Gantt, Spartanburg, S. C.

Orthopedic Club to Meet.—The next meeting of the Central States Orthopedic Club will be held in Detroit and Ann Arbor, Mich., December 28 and 29, under the presidency of Dr. Albert H. Freiberg, Cincinnati. The first day's meeting will be held in Detroit and in the evening the club will be the guest of the Detroit Medical Society. The second morning will be spent in the clinics and laboratories of the University of Michigan, Ann Arbor.

Good Health in the Army.—In the annual report of Surgeon-General William C. Gorgas it is announced that the hospital rate for the year was the lowest on record, that typhoid fever has been virtually stamped out, that there has been less alcoholism than at any time in the history of the Army and that in spite of the large number of men on duty in the tropics, the malarial fever rate is the lowest since 1898. Surgeon-General Gorgas especially commended the high hygienic standards maintained in camps.

Measures Against Importation of Disease Into This Country at the Close of the War.—The United States Public Health Service is making preparations to prevent the entrance of disease into this country at the close of the European war. American consuls in Europe have been instructed to report the appearance of epidemics immediately to the health service and particularly to watch for cholera. The Public Health Service also has representatives of its own abroad watching for manifestations of disease. The closest inspection of immigrants is to be maintained.

Progress in Legislation Against Child Labor.—The tenth annual report of the National Child Labor Committee compares the laws on this subject in 1904, when the committee was organized, with those of 1914. The number of states which impose a 14-year-age limit on all factory work has increased from thirteen in 1904 to fifty-six in 1914. In the same time the number of states having an eight-hour day for older children has increased from one to eighteen. Night work was prohibited for children under 16 in 1904 in five states, and in 1914, in thirty-four states. Factory inspection was provided for in thirteen states in 1904 and in thirty-four states in 1914.

Foot-and-Mouth Disease.—The federal quarantine against the foot-and-mouth disease has been extended to New Jersey, Rhode Island, Massachusetts, New York, Ohio, Pennsylvania, Indiana, Illinois, Maryland, Michigan, Wisconsin, Delaware and Iowa. Shipments of live stock from Canada to the United States are also forbidden. There is no evidence yet of foot-and-mouth disease in Canada, but it is intended to prevent the return of infected cars which have been sent over the border. State quarantine has also been declared against states not yet under federal quarantine. Suspected cases of infection of human beings are said to have occurred in Akron and Cleveland, Ohio; Berrien County, Mich.; Providence, R. I., and Anderson, Ind. The Rockefeller Institute for Medical Research through its director, Dr. Simon Flexner, has undertaken to investigate the cause of the disease.

Southwestern Physicians Elect Officers.—At the ninth annual meeting of the Medical Association of the Southwest held in Galveston, Tex., November 10 and 11, the following officers were elected; president, Dr. Jefferson D. Griffith, Kansas City, Mo.; vice-presidents, Drs. Ernest F. Day, Arkansas City, Kan.; Thomas H. Flesher, Edmond, Okla.; Arthur E. Sweatland, Nacogdoches, Tex., and Estill D. Holland, Hot Springs, Ark.; secretary-treasurer, Dr. Fred H. Clark, El Reno, Okla. (reelected for the tenth time), and executive committee, Drs. Matthew M. Smith, Dallas, Tex.;

John H. Barnes, Enid, Okla.; Jacob G. Dorsey, Wichita, Kan.; William H. Stauffer, St. Louis, and Edward H. Martin, Hot Springs, Ark. The association approved the adoption of the *Southwestern Journal of Medicine and Surgery* as the official organ of the association. Oklahoma City was selected as the next place of meeting and the secretary was directed to extend an invitation to the state medical bodies of Colorado, New Mexico and Louisiana to affiliate with the association.

National Economic Problems to be Discussed by the Civic Federation.—Among the national problems of medical interest to be discussed by the National Civic Federation at its fifteenth annual meeting in New York City, Dec. 3 to 5, 1914, will be that of food and drugs. The committee on plan and scope for the proposed department on food and drugs will report recommendations based on answers to a questionnaire sent out to over 5,000 federal, state and municipal drug, food and public health officials as well as to manufacturers and retail dealers. The questionnaire dealt with the conditions of the sale of meat, poultry, milk, eggs, pastry, drugs, etc., and included an inquiry as to proprietary remedies and the advisability of the adoption of an official standard of drugs to be supervised by the government. Among the topics discussed in the report of the welfare department also are several which have a medical bearing such as that on industrial fatigue, relation between hours of work and output and physical examination of new employees. In connection with this department, a permanent exhibit is to be established on the thirty-fifth floor of the Metropolitan Tower.

Southern Physicians Hold Meeting.—The eighth annual meeting of the Southern Medical Association was held in Richmond, Va., November 9 to 12, under the presidency of Dr. Stuart McGuire, Richmond, and the following officers were elected: president, Dr. Oscar Dowling, Shreveport, La.; vice-presidents, Drs. Robinson C. Dorr, Batesville, Ark., and McGuire Newton, Richmond, Va.; Dr. Allen W. Freeman, Richmond, Va., chairman; Dr. James A. Hayne, Columbia, S. C., vice-chairman; and Dr. Waller S. Leathers, University, Miss., secretary of the section of public health.——Dr. Joseph B. Greene, Ashville, N. C., chairman; Dr. Edward H. Cary, Dallas, Tex., vice-chairman, and Dr. Thomas W. Moore, Huntington, W. Va., secretary of the section on eye, ear, nose and throat.——Dr. Isidòre Cohn, New Orleans, chairman; Dr. John H. Blackburn, Bowling Green, Ky., vice-chairman, and Dr. Franklin Webb Griffith, Asheville, N. C., secretary of the section on surgery.——Dr. William H. Deaderick, Hot Springs, Ark., chairman; Dr. Charles L. Minor, Asheville, N. C., vice-chairman, and Dr. Stewart R. Roberts, Atlanta, Ga., secretary of the section on medicine. Dallas, Tex., was selected as the next place of meeting.

United States Civil-Service Examination.—The United States Civil Service Commission announces an open competitive examination for epidemiologist, for men only. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Public Health Service for service in the field, at a salary of $4,000 a year, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy bv reinstatement, transfer or promotion.

The duties of the position will be to make laboratory and field investigations of the diseases of man in relation to prevalence, causation and methods of control, and to conduct field studies of public health matters. Competitors will not be assembled for examination, but will be rated on the following subjects, which will have the relative weights indicated: Education, 25; Experience and fitness, 50; Publications, 25.

Graduation with an A.B. or B.S. degree from a college or university of recognized standing, and graduation with an M.D. degree from a medical school of recognized standing, and at least five years' experience in epidemiologic research, including field studies and laboratory technic, and at least five years' public health service under federal, state or municipal authorities, are prerequisites for consideration for this position. Experience in epidemiologic research and experience in public health service may be concurrent. Applicants must have reached their twenty-fifth but not their fortieth birthday on the date of the examination. Persons who meet the requirements and desire this examination should at once apply for Forms 304 and 2095, stating the title of the examination for which the forms are desired, to the United States Civil Service Commission, Washington, D. C.

Prevention of Infant Mortality.—The fifth annual meeting of the American Association for Study and Prevention of Infant Mortality was held in Boston, November 12-14. At the close of the meeting Mr. Homer Folks of New York, who was elected a year ago, became president for 1915, succeeding Dr. J. Whitridge Williams of Baltimore, and the following officers were elected: president-elect, Dr. Samuel McC. Hamill, Philadelphia; vice-presidents, Drs. William C. Woodward, Washington, and William Palmer Lucas, San Francisco; secretary, Dr. Philip Van Ingen, New York; treasurer, Mr. Austin McLanahan, Baltimore; executive secretary, Miss Gertrude B. Knipp, Baltimore. The meeting was the largest in the history of the association. Delegates were present from eighteen states, the District of Columbia, Canada and Panama. Over 120 organizations engaged in baby-saving work are now identified with the association. Fifty-two of these were represented by delegates at the meeting. In connection with the meeting an interesting exhibit of local and national activities was held in the Boston Public Library. The selection of place and date for the 1915 meeting were left to the incoming executive committee.

The second day's session of the association was opened by the election of the following new directors: for five years, George R. Bedinger, Boston; Dr. Sara Josephine Baker, New York; Dr. Arthur B. Emmons, 2d, Boston; Dr. William W. Butterworth, New Orleans; Dr. Charles V. Chapin, Providence, R. I.; Dr. Frank S. Churchill, Chicago; Miss M. F. Etchberger, Baltimore; Dr. Charles L. Furbush, Philadelphia; Dr. Clyde E. Ford, Cleveland; Dr. Caroline Hedger, Chicago; Dr. William Palmer Lucas, San Francisco; Dr. Helen MacMurchy, Toronto; Harold McCormick, Chicago; Dr. Fred W. Schutz, Minneapolis; Dr. George M. Tuttle, St. Louis; Dr. Borden S. Veeder, St. Louis; Dr. William H. Welch, Baltimore; for four years, Dr. Howard C. Carpenter, Philadelphia; for three years, Dr. Watson S. Rankin, Raleigh, N. C., and Dr. Ernest C. Levy, Richmond, Va.; for two years, Dr. Carl L. Alsberg, Washington; for one year, Mrs. C. B. Crane, Kalamazoo, Mich.

FOREIGN

New University in Austria-Hungary.—Austria-Hungary has just founded a new university, the fifth in the empire. It is located at Presburg, in Hungary, about 40 miles east of Vienna. It was inaugurated with simple ceremonies, October 4.

Yellow Fever Suspects.—Two passengers on the steamer "*Esperanze*" from Progreso, Mex., which arrived at Havana, November 16, showed signs of yellow fever and were isolated for observation. Two cases of yellow fever are reported at Merida, Yucatan.

WAR NOTES

The American Ambulance.—The American Ambulance Society, Paris, has found it possible to convert an ordinary motor car into an ambulance at a cost of $50.

Medical Graduating Class Proceeds to the Front.—Prof. G. Reinhold is the newly elected rector of the University of Vienna, and he conferred the degrees on the graduating class in the medical department, October 2. The graduated physicians all entered the army at once. About twenty of them were already in uniform at the graduating exercises.

Hospital Ship Wrecked.—The hospital ship *Rohilla* en route from Queensferry, Firth of Forth, to Belgium for wounded, was wrecked off Whitby, October 30, with considerable loss of life. None of the medical officers or nursing sisters was lost. The crew and passengers were rescued by the ship's boats and the Whitby life boat.

Dearth of Medical Officers.—The British Expeditionary Force is said to be so short of medical officers that those they have are seriously overworked. It is suggested also that there is a lack of medical supplies. The demand for motor ambulances is very great and the London *Times* has raised a fund of nearly $2,000,000 to supply this demand.

War Surgery.—In the *Journal des Débats* appears an article by Henry de Varigny dealing with the subject of amputations in the present war. During the first month of surgical work at the Vichy Hospital more than 600 operations were performed, a very small number in comparison with the number of wounded, which was not less than 6,000. Of these 600 operations in the past month of war service, not ten amputations were recorded and the majority of these were minor.

Return on the Red Cross Ship.—The steamer *Red Cross,* which was sent to Europe by the American National Red Cross, with surgeons, nurses and medical supplies, returned to New York October 24. Rear Admiral Aaron Ward, U. S. N., who has charge of the work of distribution of supplies, laid special stress on the hospitality of the Hollanders. The stevedores at Amsterdam refused pay for their services; the Rotterdam Dry Dock Company declined payment for engine repairs and the Holland Railway Company transported four Red Cross units and more than 100 tons of supplies to the German frontier free of charge. The *Red Cross* brought home 150 refugees from Europe.

Work of the British Red Cross.—The pressure on the British Red Cross organization was exceedingly severe during the first week of November, during which nearly 10,000 soldiers were removed from trains to hospitals. The Royal Army Medical Corps handled the emergency admirably and the service was well equipped in every particular. The organization is rendering considerable help to the French, a large number of surgeons and dressers have been sent to Rennes and Calais to work among the French wounded. A body of surgeons was also sent to Dunkirk to look after the Belgian wounded. The first British Red Cross Hospital is now ready with a capacity of about 500 and motor ambulances are being placed in the field as rapidly as possible.

Deaths in the Profession at the Front.—Austria reports the death at the front of Drs. F. Haritz, Vienna; F. Mayer, A. Selinger, B. Mund; N. Ruczka and L. Stern.——The Vienna Medical Society has lost at the front three of the younger members, A. Jungmann, L. Grünfeld and E. Venus.——In Germany the list of medical officers killed on the firing line includes R. Gottschalk, A. Bertheim, the chemist collaborator of P. Ehrlich, killed by accident on his way to the front; L. Kirchheim, assistant at the medical clinic at Marburg, aged 38; F. Meyer-Betz, and G. Herrenschneider. The *Münchener med. Wochenschrift* has published up to and including the issue for October 20, the names and titles of sixty-four physicians and medical officers and of nine last-year medical students, a total of seventy-three, besides several missing.

Red Cross Hospital Train.—A hospital train, said to be the most complete and efficient moving hospital ever constructed, has been given by the Hamburg Red Cross and is now in operation on the western battle front. The train has 36 cars, including 29 for the transportation of the seriously wounded, and 278 beds; a magazine car; a baggage car; a supply car; a physicians' car; an apothecary car; and a car for the hospital corps. Beds with spring mattresses and furnished with laundered linen and fresh blankets are supplied for the sick. The cars are fitted with every conceivable sanitary convenience and the beds are so constructed that they may be used as stretchers. One-half of the physicians' car is divided into compartments for the use of the physicians, while the other half contains a dining and consultation room.

The Wounded Servians.—A European journal gives an alleged extract from the diary of a dead German officer regarding the wounded Servians: "When one leaves the organized hospitals and wends one's way through the crowds of wounded who block the pavements and enters a lower-class café, the appalling tragedy of it all fills even the spectator with a sense of hopelessness. There, like cattle on their bed of straw, lie sufferers from all manner of hurts. They remain mute and uncomplaining, just as they have been dropped down from the incoming oxen transports. Their wounds—3, 4 or 5 days old—have yet received no attention save the primitive first aid of the battle-field. Blood poisoning is setting in; limbs that prompt dressing would have saved are fast becoming victims for the surgeon's knife. Most of them know the risk they run, for this is their third war—often, too, their third wound—in two short years. Yet the doctors cannot come, because every man of them is already doing more than human energy allows. It is a heart-rending sight to look down on this helpless mass and to realize that many of them have been sentenced to painful death for mere lack of primitive medical attention."

Amateur Nursing.—The *Deutsche med. Wochenschrift* says that the physicians and surgeons at the German front are grateful indeed for the thorough sifting process applied by the authorities to the crowds of women who volunteer to nurse the wounded and sick. The medical staff of a hospital is never very enthusiastic over "dilettante nurses." One volunteer nurse complained recently that the night service was too long; she thought six hours was long enough. Another was distressed because the day shift went on duty at 7; she was not used to getting up so early. Another did not want to have anything to do with tuberculous patients and she had to be transferred to the quarters of the wounded and her chum with her, as they would not be parted. Amateur nurses have such a preference for the care of the wounded that the Red Cross now will not accept them unless they agree to tend the sick with internal diseases as well as the wounded at need. These recent happenings, it is said, confirm the wisdom of the authorities in permitting scarcely any but trained nurses to be sent to the front. Extensive arrangements have now been made, however, to train nurses and attendants. All the public hospitals, the Red Cross and numerous other institutions are making every effort to train large numbers of nurses. The municipal sterilizing plants are sterilizing dressings and clothing donated for points outside. The *Medizinische Klinik* comments: "Thus the city of Berlin has shown in every way its preparedness for war (*Kriegsbereitschaft*)."

German and Austrian Physicians Decorated for Gallantry at the Front.—Austria reports that Dr. J. Winter has been knighted for distinguished service in the field and in the prevention of epidemics; the German Kaiser has also conferred a decoration on him. Other Austrian orders have been conferred on G. Arnstein, K. Wolfgang, R. Pollak, E. Bayer, F. Baruch, A. Lerch, V. Eisenmenger and K. Kaunitz. Official recognition for heorism on the firing line mentions the names of Drs. E. Hochmann, A. Polacco and F. Fischer in the latest published list. In Germany the iron cross awarded for special acts of gallantry has been given to 120 members of the profession, including nineteen professors who went from the lecture room to the front. Others besides those already mentioned in these columns are von Angerer, C. Engel, Graser, Riese, Schlayer, Thiemich, Ullmann, Wullstein, Müller of Munich, Lange, Benario, Berghaus, Kausch, Loening, Rumpel, Lennhoff, Stiertz, Küttner and Wachsen. The *Medizinische Klinik*, November 1, adds several more names to the list, among them that of T. v. Olshausen, a member of its editorial staff. This exchange is published by a syndicate of forty-eight physicians and nearly all are at the front, and most of them are already recipients of the iron cross. Bier is in this, and also is one of the group of fifteen that publish the *Münchener med. Wochenschrift*. Most of these also are on the list of those to whom the iron cross has been presented.

Transportation of the German Wounded.—The *Deutsche med. Wochenschrift*, October 15, publishes an official communication from the state war department deprecating suggestions from others in regard to the transportation of the wounded. No matter how well meant the suggestions, it says, if they are impractical or conditions forbid their being carried into effect, they merely render the public uneasy to no purpose. The communication is a reply to an article by Czerny in a previous issue in which he made a few suggestions, and his words were widely copied in the daily papers. The communication from the war department states further that theoretically it is in complete accord with most of Czerny's remarks, but all who have been out on the firing line know that there theory and actual practice—as so often happens in war—are worlds apart. "During the first of the campaign the army pushed forward so rapidly that no attempt was made to have the hospital organization keep up with it. The wounded were rushed back from the danger zone by thousands and thousands, and as the railroads had been destroyed, this was a difficult task, but the wounded all preferred to be sent back rather than to be left on the firing line. The hospital trains could not get down to the front, as the tracks were clogged with trains loaded with troops and supplies, so that there were no means of transportation for the wounded except freight trains. More than 120 trains were sent out, each carrying from 300 to 500 wounded. But all were well bandaged and able to bear the transportation. In order to accomplish this, the medical staff had to work with the utmost devotion at high pressure day and night. Only those not seriously wounded were sent back by train. The medical staff made strict provision for a medical force and attendants to accompany each train. If such was lacking at any point those who had the matter in charge were held to strict account. At present there are fifty hospital trains running, with practically clear passage from the front to the home zone.

"Each is fully equipped with physicians and nurses and everything needed for the transportation and care of the wounded, kitchen car, operating room, etc. If the tracks should again become congested with other trains—which is not impossible—then the freight trains will have to be utilized again, but provision has been made so that at many stations, especially those on the frontier, there are already ample supplies of blankets, mattresses, heaters, etc., with medical and other attendants, so that each train can be fitted out properly. The suggestion that one wall of the freight car be taken out is not practicable."

LONDON LETTER

London, Nov. 6, 1914.

Treatment of the Wounded

Though most of the wounds received in the war are slight and recovery from them takes place rapidly, some are of great severity and attended by complications, of which tetanus and emphysematous gangrene are the most important. The bacteriologic conditions are peculiar and novel to our bacteriologists working at the front in northern France. In England wound infection is almost exclusively due to staphylococci and streptococci. In France the infecting organisms usually are of the anaerobic class, such as the tetanus bacillus, the *Bacillus aerogenes capsulatus* and the bacillus of malignant edema. Only after a considerable time and sometimes not at all does ordinary pus form. The reason of the difference is that the soil of France and Belgium is cultivated to a degree unknown in England, what is known as "intensive cultivation." It has been thoroughly manured for many years and therefore teems with the anaerobic organisms which inhabit intestines of domestic animals. The soldiers standing in the trenches for hours get their clothing and hands caked with mud. A missile which hits them carries in with it these anaerobes.

The infections induced are serious and frequently fatal. A great improvement has been made in the transportation of wounded from the front. The time now occupied is much shorter and instead of mere trucks, thoroughly equipped ambulance trains are used. Each is provided with a staff of not fewer than three surgeons, four women nurses, and a number of orderlies. Everything necessary for the changing of dressings, and even for the performance of an operation by running the train into a siding, is provided. The feeding of the patients during transit has not been forgotten; there are one or more kitchens on each train. Now that the British army instead of facing north from the east of Paris has been moved into the north of France on the Belgian frontier and faces east, the distance from England is much shortened and the French seaports on the English Channel have become veritable hospital towns. Large buildings such as casinos have been converted into hospitals and in consequence of their good lighting and ventilation answer admirably. The hospitals have far larger professional staffs than the official regulations require, and, thanks to the system of specialization introduced in the Army Medical Corps about ten years ago, the staff of each includes at least one man who is a thoroughly skilled and experienced operating surgeon. Furthermore, of the men who have been enlisted as temporary surgeons, many have had considerable surgical experience. A good many of them are fellows of the Royal College of Surgeons of England. From these hospitals the wounded who are fit for the journey are sent home in splendidly equipped hospital ships, which are large transatlantic liners that have been converted. The bulkheads have been removed and the place of small cabins taken by large wards. The ships are well staffed with surgeons, nurses and orderlies, and the passage, which takes only a few hours, is accomplished without inconvenience. Many thousands of wounded are now in this country distributed in the hospitals throughout the British Isles. Mr. D'Arcy Power, surgeon to St. Bartholomew's Hospital, and lieutenant-colonel attached to the first London general hospital for the reception of the wounded, gives his impressions of the treatment in the *Lancet*. He finds that as in ordinary civil practice, the net result of the work appears to show that meddlesome surgery is generally bad surgery. Wounds need no longer be probed, drained and packed. Tempered with discretion, it is better to wait than to operate unless the patient is losing ground. Considerable experience, however, is required to decide when to wait and when to operate, because injuries which appear slight superficially may conceal conditions that demand immediate treatment. Looking to the fact that the chief infection seems to come from the patient's own skin, antiseptic surgery is preferable to aseptic methods. Dry dressings must give place to compresses and fomentations whereever possible. Iodin applications seem to be more effective than the solutions of mercuric chlorid and mercuric iodid, which have hitherto been the more generally used. The youth and health of the patients render the prognosis even of severe injuries correspondingly good and enable the surgeon to take waiting risks which might otherwise be hazardous. It is better, therefore, to err on the conservative rather than on the radical side of surgery, at any rate in the earlier stages.

THE BELGIAN WOUNDED IN ENGLAND

The advance of the Germans through Belgium led to the constant removal of the wounded from one hospital base to another. At length when driven to the sea the wounded were embarked in large numbers for England. One night some thousands were landed at Folkestone. The scene of landing was weird in the extreme. The whole town was in darkness—a military precaution adopted in the coast towns. A large hotel was prepared for their reception into which they were conveyed by physicians, medical students acting as dressers, and nurses who were hastily sent down from London. By the aid of electric torches, tripping over the flower beds of the hotel was avoided. The more seriously wounded were investigated on board the ships and sent in motor ambulances to the nearest military hospital. The rest were placed in ambulance trains and sent to various hospitals. As in the case of the British soldiers, most of the wounds were due to shells, the majority being in the upper limbs.

Dispensary for Belgian Refugees

A dispensary has been opened under the auspices of the War Refugees Committee for the medical treatment of sick Belgian refugees. The enormous influx of refugees, many of whom speak only Flemish, has rendered it necessary to organize medical relief to secure separate quarters, and to take advantage of the services of Belgian physicians who have found an asylum in this country. Arrangements have been made for a service of consultations daily, and they are now in full working order with an efficient staff of nurses of the British Red Cross. Many Belgian physicians now in London, some of whom are well-known specialists, have offered their assistance for consultation in special cases.

War the Absorbing Topic

The war, of course, is still the all-absorbing topic. It fills the newspapers almost to the entire exclusion of everything else. There is not a very great deal of special medical interest, however, forthcoming at present—apart from the scientific reports on the casualties of war which are not public property yet. Our hospitals, military, permanent and extemporized, are filling up with wounded who have been successfully transported from the area of war, but generally speaking, notwithstanding the conditions of hardship and exposure, to which from the conditions and sanguinary nature of the fighting, the wounded are exposed, often without shelter and food, for hours, sometimes even for days, it is positively remarkable how well the majority of the patients do when they get here; though now that the fighting takes place actually nearer here than to the French base and we get the cases earlier, we are getting a large proportion of more severe wounds.

Casualties and Rewards

The casualties in the medical corps continue to be heavier than in previous wars. Since my last report six officers of the Royal Army Medical Corps have been killed, one wounded and one reported missing. A particularly sad one is that of a young Australian doctor, Captain Brian Pockley, of the Australian Naval Reserve. He was the son of a prominent Sydney (N.S.W.) doctor, a former president of the Australasian Medical Congress, and graduated at the University of Sydney only this year. He was engaged with a landing party in New Guinea from an Australian warship, and finding a wounded sailor had to be sent to the rear, placed his Red Cross coat on the sailor who carried the wounded man, to indicate that he was temporarily non-combatant. While without his coat attending another wounded man he was shot by a German officer who failed to recognize his protected character in the absence of his badges. Captain Pockley was only 24 years old. As a set-off to the casualties it may be mentioned that the French Cross of the Legion of Honor has been bestowed on three officers of the Royal Army Medical Corps, Major S. L. Cummins and Captains S. E. Lewis, J. T. McEntire, H. S. Ranken, the last of whom has, unfortunately since died from his wounds.

The Indian Wounded

The care of our wounded Indian soldiers, which on account of caste, questions and other details at one time seemed likely to be a difficult problem, has now been satisfactorily settled. At Netley Hospital, a considerable number have been received under the care of Colonel Sharman, of the Indian Medical Service, who has a staff of sixty Indian orderlies. Two hotels also have now been chartered by the government at Brockenhurst near Southampton, where the wounded land and whence they are transported by motor ambulances.

These two hospitals will accommodate 2,500 patients. Huts are also to be erected in Brockenhurst Park to accommodate a further 500. Their staff will consist of eleven medical officers and thirty orderlies. The enthusiasm in England over the brilliant and devoted service rendered by the Indian troops has stirred up a grateful activity to see that they lack for nothing from the native viewpoint. A large number of Indian residents, including many of very high position, barristers, educationists, and even retired native officers of the Indian Medical Service, have offered their services to Netley as orderlies. The Indians make wonderful patients, as they are redoubtable and marvelously disciplined fighters, and their loyalty and devotion to the empire are a revelation to those who have not hitherto realized it from experience in India.

The Order of St. John of Jerusalem

The Order of St. John of Jerusalem, the English League of the Knights of Malta, has now united its forces with the British Red Cross under Director-General Arthur Sloggett. The order has 107 hospitals, containing 4,610 beds, England; also seventy-eight convalescent homes with 2,665 beds. Of these hospitals twenty-eight are in use and fourteen are now mobilizing. The order has also three hospitals of 100 beds each in France.

PARIS LETTER

PARIS, Nov. 5, 1914.

Treatment of Gangrenous Military Wounds

October 21, Dr. Quénu, professor of clinical surgery at the Faculté de médecine de Paris, read an interesting paper on this subject before the Société de chirurgie. He did not agree with Dr. Delorme (THE JOURNAL, Oct. 24, 1914, p. 1492), that the treatment of gaseous gangrene should consist of subcutaneous or subaponeurotic injections of hydrogen peroxid. Quénu believes in free opening of the wound and scrupulous disinfection of the cavities with removal of foreign bodies and loosened fragments. Hydrogen peroxid is sufficient to disinfect superficial gangrene, but for gangrene extending into the depths of muscular masses Quénu uses hot air raised to 500 or 600 C. brought into contact with the gangrenous parts by a tube. The hot air first dries and then mummifies the gangrenous surfaces. A certain amount of time is necessary for this sterilization by heat, and large specula must be used like those employed in vaginal operations to sterilize the most remote crevices without danger of carbonizing the muscles and affecting the subjacent tissues too deeply. The large vascular and nerve trunks must be avoided and the hot metal tube must not be brought into contact with the tissues, which would cling to it, producing a closed cavity in which the air-pressure might cause accidents. The end of the tube must be held at a distance of some centimeters from the tissues and the various pockets in the wound must be reached. The following days the wound is to be washed with hydrogen peroxid. The little dried scars are quickly eliminated and the bottom of the wound soon shows a healthy pink tint.

Tincture of Iodin for the Use of Soldiers

It is well known that bullet wounds immediately painted with tincture of iodin in the majority of cases are aseptic and benign. Similar painting done in ambulances where the soldiers are not received until hours or even days after having been wounded, is likely to be inefficacious. To do good, tincture of iodin must be applied at once, and this is possible only if the soldiers themselves are able to apply it. To provide the soldiers with tincture of iodin in a utilizable form without encumbering them too much is a problem which presents great practical difficulties. Iodin tablets, which are quite practicable for the ambulances, are not so for the soldiers, who have no facilities for dissolving them. A pharmacist in Paris, M. Ronert, has produced sealed ampules about 6 mm. (nearly a quarter of an inch) in diameter and about 6 or 7 cm. (2 inches) long containing tincture of iodin mixed with an iodid to make it unchangeable, and put up in a little case, taking up no more room in the pocket than a little pencil. Near one end the ampules are constricted and filed so as to break readily in the hand. Each one contains a cotton applicator and sufficient iodin to paint the wound and surrounding skin, and costs 10 centimes (about 2 cents). Dr. Pierre Delbet, professor of clinical surgery at the Faculté de médecine de Paris, has found them very practicable, and the Baroness Henri de Rothschild, who supports and directs an auxiliary hospital, has offered to give the army 200,000 ampules.

The Nobel Prizes

The Swedish scientific institutions which award the Nobel prizes have decided, in view of the European situation, to postpone the distribution of the prizes in literature, medicine, chemistry and physics until next year. The assent of the government is needed, but it is regarded as certain to be given.

The Situation of Students in the Army

The reopening of the departments of the universities has caused some families to fear that an unfair advantage would be given the students not in the army over those who are in the ranks. The minister of public instruction has just issued a promise that all measures will be taken to safeguard the rights of the students who are defending the country. Special examinations will be held, courses will be given for their benefit and competitive examinations will be adjourned until after the end of hostilities.

Privileges for Belgian Physicians

At its last session, the Académie de médecine decided to ask for Belgian physicians who have taken refuge in France the privilege of practicing their profession in the numerous localities which have been deprived of medical assistance by the general mobilization.

Thanks to the American Colony

M. Georges Lecomte, president of the Société des gens de lettres, recently presented to the American ambassador most hearty thanks for the remarkable work of the American hospital in Paris. "The admirable attentions lavished by eminent American physicians and surgeons," said M. Lecomte, "and the devotion of the whole American colony has filled our society with enthusiasm and gratitude."

Personal

Dr. Marfan, professor of therapeutics at the Faculté de médecine de Paris, has been, at his own request, appointed professor of the hygiene and clinical medicine of early infancy in the school.

The *Journal Officiel* has just published a note in which the government expresses the gratitude of the country for the noble conduct of Dr. Langlet of Reims "who has been to his fellow citizens a most noble example of coolness, courage and dignity during the occupation and bombardment of the city."

Marriages

FRED DESIRÉ LA ROCHELLE, M.D., Springfield, Mass., to Miss Elizabeth Sarah Henstridge of Hamilton, Ont., November 7.

JAMES HENRY MCKELLAR, M.D., Pasadena, Cal., to Miss Dorothy Kellogg of Altadena, Cal., at Pasadena, November 4.

WILLIAM ALEXANDER BOYD, M.D., Baltimore, to Miss Harriet M. Shannon of Washington, D. C., November 4.

STANLEY HENRY MELLEN, M.D., New York City, to Miss Hazel May White of Newark, N. J., November 4.

WALTER EDGAR STEWART, M.D., Cushing, Okla., to Miss Ethel Gill of Hattiesburg, Miss., October 18.

RICHARD DALE HOPKINSON, M.D., to Miss Florence A. Savage, both of Philadelphia, November 4.

FLETCHER LANGDON, M.D., Cincinnati, to Miss Elizabeth Inman of Winchester, Ind., November 5.

CHARLES NEWTON HAHN, M.D., Dunnegan, Mo., to Miss Clara Flint of Cliquot, Mo., October 21.

FRANK HENRY MORROW, M.D., to Miss Catheryne Rusche, both of Columbus, Neb., November 4.

ROBERT MOFFET PALMER, M.D., to Miss Olive Meyer, both of Johnstown, Pa., October 28.

HENRY F. DEICHER, M.D., to Miss Anna Kohl, both of Plymouth, Wis., November 4.

FRANKLIN BENNETT MCCARTY, M.D., to Miss Mary Bryan, both of Chicago, October 31.

WILHELM HENRY VORBAU, M.D., to Miss May Hearn, both of Athens, Ohio, October 8.

JAMES F. DEVIN, M.D., to Mrs. Fannie Conger, both of Seattle, Wash., October 29.

DAVID GORDON, M.D., to Mrs. O. D. Fields, both of Chillicothe, Mo., October 28.

Deaths

Charles Sedgwick Minot, S.D. Harvard, 1878; James Stillman professor of comparative anatomy and director of the laboratory of anatomy at Harvard Medical School since 1905; formerly lecturer on embryology; instructor in oro-pathology and surgery; instructor and assistant professor and professor on histology and embryology in his Alma Mater; Harvard exchange professor at the Universities of Berlin and Jena in 1912 and 1913; eminent as an anatomist; member of many learned societies; author of numerous papers on anatomy, embryology and biology; died at his home in Boston, November 19, aged 61.

John Shrady, M.D. College of Physicians and Surgeons in the City of New York, 1861; a member of the Medical Society of the State of New York and once president of the New York County Medical Association; formerly editor of the *Medical Register*; for fifty years a practitioner of Harlem, N. Y., where he was familiarly known as the "Little Father of the Poor"; a veteran of the Civil War, in which he served as surgeon of the Second East Tennessee Volunteer Infantry and a captive in Libby Prison; died at his home in Stamford, Conn., November 11, aged 84.

John Augustus Horgan, M.D. Harvard Medical School, 1888; a Fellow of the American Medical Association and a resident of Roxbury for more than twenty-five years; president of the St. Vincent De Paul Society of Boston, and visiting physician to the Foxboro State Hospital; died at his home in Roxbury, Boston, November 11, after a surgical operation, aged 59.

Eugene A. Hutchins, M.D. Berkshire Medical College, Pittsfield, Mass., 1862; for thirty years a practitioner of Minneapolis; a member of the Minnesota State Medical Association; consulting physician to the Asbury Hospital, Minneapolis; died in that institution, November 9, after a surgical operation, aged 76.

William Theodore Fletnitz, M.D. University of Basle, Switzerland, 1895; National Medical University, Chicago, 1901; a Fellow of the American Medical Association; formerly treasurer of the Central-Western Kansas Medical Society; died suddenly at his home in Kansas City, Mo., November 1, aged 47.

Wilson R. Priest, M.D. Medical College of Ohio, Cincinnati, 1886; a member and once president of the Kansas Medical Society; local surgeon at Concordia, Kan., for the Missouri Pacific and Santa Fe systems; chief surgeon to St. Joseph's Hospital, Concordia; died at his home November 10, aged 54.

C. Milo Brady, M.D. Tulane University, New Orleans, 1893; medical inspector of the Louisiana State Board of Health for a time; for several months a student of tropical diseases on the West Coast of Africa and in Mexico; died at the home of his father in Waggaman, La., November 5, aged 45.

Thomas Benton Spaulding, M.D. New Orleans School of Medicine, 1860; assistant surgeon to the Fifteenth Louisiana Volunteer Infantry, C. S. A., during the Civil War, and later a practitioner of Kingston and Greenville, Texas; died at the home of his daughter in Dallas, Texas, October 27, aged 74.

Jacob Lopes Cardozo, M.D. Medical College of the State of South Carolina, Charleston, 1878; chief of staff of the Gates Avenue Dispensary and physician to the Eastern District Dispensary, Brooklyn; died at his home in Brooklyn, November 3, from senile debility, aged 82.

Joseph Lewis Powers, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1876; formerly health officer of Reinbeck, Iowa; but for several years a resident of Waterloo; died at the home of his daughter in that city, October 29, from cerebral hemorrhage, aged 90.

Joseph P. Mellard, M.D. Medical College of the State of South Carolina, Charleston, 1872; formerly a Fellow of the American Medical Association; a member of the South Carolina Medical Association; died at his home in St. George, S. C., October 12, aged 76.

Walter C. Stillwell, M.D. University of Pennsylvania, Philadelphia, 1873; a member of the Medical Society of the State of Pennsylvania and for many years a druggist of Philadelphia; died at his home in that city, November 14, from cerebral hemorrhage, aged 63.

Henry H. Pemberton, M.D. Jefferson Medical College, 1872; Hahnemann Medical College, Philadelphia, 1873; for forty years a practitioner and real estate broker of Long Branch, N. J.; died at his home in that city, November 11, from heart disease, aged 65.

Simon Preston Brown, M.D. Rush Medical College, 1869; for more than forty years a practitioner of Elgin, Ill.; died at his home in that city, November 7, from senile debility, aged 82. At his funeral eight physicians of Elgin served as active pallbearers.

John Wilson Hammonds, M.D. University of Nashville, Tenn., 1867; surgeon in the Confederate service throughout the Civil War; for nearly half a century a practitioner of Sevier County, Ark.; died at his home in Chapel Hill., Ark., October 28, aged 75.

Charles Buchanan Martin, M.D. University of Pennsylvania, Philadelphia, 1887; for several years a practitioner of Tacoma, Wash., but since 1903 a resident of Quarryville, Pa.; died at the home of his sister in that place, October 26, from nephritis, aged 53.

Osmon Baker Way, M.D. Dartmouth Medical College, Hanover, N. H., 1866; a member of the New Hampshire Medical Society and a well-known physician of Claremont, N. H.; died in Brattleboro, Vt., October 26, from arteriosclerosis, aged 74.

Ward Beecher De Long, M.D. Ensworth Medical College, St. Joseph, Mo., 1906; a member of the Missouri State Medical Association and a practitioner of Saline, Mo.; was killed by the overturning of his automobile near Saline, November 8, aged 43.

Thomas Lafayette, M.D. University of Lyons, France, 1844; a pioneer practitioner of Southwestern Missouri and assistant surgeon of Volunteers throughout the Civil War; died at his home in Hopkins, Mo., August 16, from senile debility, aged 95.

Wilfred V. Stephenson, M.D. University Medical College, Kansas City, Mo., 1905; of Mound City, Kan.; a Fellow of the American Medical Association; died in Wesley Hospital, Kansas City, Mo., November 10, from heart disease, aged 35.

Andrew Sprague Oliver, M.D. Hahnemann Medical College, Philadelphia, 1881; for four years a member of the board of public library trustees of San Jose, Cal.; died at his home in that city, November 8, from cerebral hemorrhage.

Thomas Walker Stone, M.D. Louisville (Ky.) Medical College, 1884; of Los Angeles, Cal.; formerly a member of the faculty of the medical College of Evansville, Ind.; died in the Stockton, Cal., State Hospital, November 6, aged 59.

John F. Campbell, M.D. University of Michigan, Ann Arbor, 1876; a Fellow of the American Medical Association and for fifteen years a member of the board of education of Lansing, Mich.; died at his home in that city, November 3, aged 61.

Samuel Stem Apple, M.D. Jefferson Medical College, 1869; a member of the Medical Society of the State of Pennsylvania and a veteran of the Civil War; died at his home in Easton, Pa., November 11, from senile debility, aged 75.

Alexander Donaldson McDonald, M.D. Washington University School of Medicine, Baltimore, 1877; a member of the Medical Society of the State of North Carolina; died at his home in Wilmington, N. C., November 7, aged 82.

James Webster Belden, M.D. Tulane University, New Orleans, 1888; of New Orleans; died in Touro Infirmary, New Orleans, November 7, from carcinoma of the intestine, three days after a surgical operation, aged 54.

Alexander Martin Heron, M.D. Medico-Chirurgical College of Philadelphia, 1899; a Fellow of the American Medical Association; formerly health officer of Lakewood, N. J.; died at his home in that place, October 11, aged 49.

John Hooker McCutchan, M.D. Starling Medical College, Columbus, Ohio, 1894; surgeon to the Evansville and Indiana Southern Traction Company at Evansville, Ind.; died in a hospital in that city, November 7, aged 44.

John N. Kerr, M.D. Starling Medical College, Columbus, Ohio, 1877; for many years a practitioner of Logan County, Ohio; died at his home in Boise, Idaho, September 4, from valvular heart disease, aged 62.

Martin Luther Knight, M.D. Tulane University, New Orleans, 1895; a member of the Mississippi State Medical Association; died at his home in Hazelhurst, Miss., July 18, from angina pectoris, aged 54.

James Ward Keeney, M.D. Bellevue Hospital Medical College, 1874; formerly a member of the board of health and police pension board of San Francisco; died in that city, November 7, aged 62.

James Alison Lee, M.D. State University of Iowa, Iowa City, 1873; for many years a practitioner of Lone Tree, Iowa; died at his home in Lisbon, Iowa, October 28, from carcinoma of the liver and mesentery, aged 66.

Edward Harvey Taft, M.D. Dartmouth Medical School, Hanover, N. H., 1897; a Fellow of the American Medical Association; died suddenly at his home in Milford, N. H., November 4, aged 45.

Alvah Miller Wilson, M.D. Washington University Medical School, St. Louis, 1896; formerly a Fellow of the American Medical Association; died at his home in St. Louis, November 3, aged 39.

Joseph Muse Worthington, M.D. University of Maryland, Baltimore, 1872; a member of the Medical and Chirurgical Faculty of Maryland; died at his home in Annapolis, September 21, aged 68.

William H. Hall, M.D. Eclectic Medical Institute, Cincinnati, 1870; died at his home in Havana, Ill., October 30, a short time after a surgical operation performed in Chicago, aged 74.

Robert K. Cherry, M.D. Leonard School of Medicine, Raleigh, N. C., 1906; a colored practitioner of Germantown, Philadelphia; died at his home, October 28, from pneumonia, aged 34.

Samuel J. Hoffman, M.D. University of Maryland, Baltimore, 1877; a member of the Medical Society of Virginia; died at his home in Woodstock, Va., from carcinoma, aged 62.

Godfrey Beaumont, M.D. University of Louisville, Ky., 1865; of Kalamazoo, Mich.; died at his summer home in Moore Park, Mich., September 26, from diabetes, aged 83.

Solomon Adams Bergman, M.D. Memphis Hospital Medical College, Memphis, Tenn., 1906; of Buck, Tex.; died in Moscow, Tex., August 1, from cerebral hemorrhage, aged 35.

Henry C. Miller, M.D. Homeopathic Medical College of Missouri, St. Louis, 1871; of Wilkinsburg, Pa.; died at the home of his sister in that place, November 2, aged 80.

Milledge Marcellus Conner, M.D. Kansas City Hospital College of Medicine, Kansas City, Mo., 1885; of Augusta, Ga.; died in the Augusta City Hospital, October 25.

Deville J. Moyer, M.D. University of Michigan, Ann Arbor, 1893; a member of the Kansas Medical Society; died at his home in Junction City, Kan., September 9, aged 52.

Edward R. Wren (license, Mississippi) for many years a practitioner of Amory, Miss.; died at the home of his son in Ensley, Ala., October 26, aged 76.

Edward Horton Flint, M.D. Hahnemann Medical College, Chicago, 1880; died at his home in Syracuse, N. Y., October 30, from pneumonia, aged 54.

George Washington Chamberlain, M.D. New York University, New York City, 1873; died at his home in Hinsdale, Mass., October 5, aged 65.

A. G. Andrews, M.D. University of Louisville, Ky., 1868; died at his home in Spring Creek, Tenn., August 16, from senile debility, aged 81.

Eugene Bonaparte Cushing, M.D. Hahnemann Medical College, Philadelphia, 1871; died at his home in Lynn, Mass., September 21, aged 68.

W. Rudolph Froelich, M.D. University of Würzburg, Germany, 1903; died suddenly at his home in Stuttgart, Ark., September 25, aged 37.

Henry Jefferson Hascall, M.D. Boston University School of Medicine, 1879; died at his home in Shrewsbury, Mass., September 19, aged 62.

Isaac Grimshaw Worrall, M.D. New York University, New York City, 1850; died at his home in Creskill, N. J., about October 26, aged 86.

Charles Samuel Sargent, M.D. Boston University School of Medicine, 1879; died at his home in Webster, Mass., September 26, aged 58.

James Thompson Wilson, M.D. University of Pennsylvania, Philadelphia, 1864; died at his home in Tyrone, Pa., September 23, aged 74.

Eugene Hinton Rencher, M.D. University of Alabama, Mobile, 1910; died at his home in Jamestown, Ala., September 17, aged 37.

Lorenzo William Thompson, M.D. Trinity Medical College, Toronto, 1885; died at his home in Listowel, Ont., September 13, aged 60.

Ethan G. Allen, M.D. Pulte Medical College, Cincinnati, 1889; died at his home in Shreveport, La., October 21, aged 58.

Correspondence

Postgraduate Education

To the Editor:—If the practicing physician would either move forward, or prevent his falling behind the times, he must avail himself at intervals of postgraduate courses. The necessity for providing these has long been recognized both at home and abroad, notably in the German Empire, but the task of properly organizing the work of postgraduate instruction is still unfinished.

In December, 1899, distinguished physicians of Berlin in collaboration with the Prussian state government organized the Central Committee of Postgraduate Medical Education in Prussia, whose duty "is fulfilled in stimulating the scientific education of practical physicians, by promoting in the larger Prussian towns the organization of local unions which take on themselves the work of arranging gratuitous courses and lectures." Of these local unions not less than thirty-one are in existence. The expenses of organization of the central committee are met by a contribution from the Prussian state government, in certain parts of the empire by subventions from local societies, and by a small matriculation fee paid by auditors. During the years from 1900 to 1906 there were called to life in other states of the confederation and in Prussia national committees for the purpose of promoting medical extension courses.

In 1908 on the initiation of the Prussian central committee, the members of state committees of the various federated states of the German empire met and founded the Imperial Federal Board for Postgraduate Medical Education. The function of the federal board consists in giving definite suggestions at occasional conferences to the chairmen of the state committees, but the latter work quite independently for their own state. These demonstratorial courses and lectures are free (a small registration fee excepted), and the lecturers receive no recompense as a rule, "but only repayment of their actual expenses."

To Germany belongs the credit of the founding in 1910 of an international committee for medical postgraduate education, and not less than fifteen countries, including the United States, are represented by delegates. This committee holds periodic conferences, generally on the occasions of the international medical congresses, at which questions of vital interest bearing on postgraduate education are discussed with a view to mutual enlightenment and stimulation.

With a view to promoting postgraduate medical education in general, and at the same time as a memorial to the Empress Friedrich, the Kaiserin Friedrich-Haus was established in 1900, solely as the result of voluntary contributions, amounting to 1,500,000 marks, and dedicated in the presence of the emperor and empress. The annual cost of maintenance is about 50,000 marks ($12,500), derived partly from the state government, partly from rentals paid by both the university and exhibitors, and finally from the foundation capital not used up in building. The present director is Prof. Dr. C. Adam, who conducts visitors through the handsome structure, pointing out its numerous and varied treasures, and also the uses to which the various portions of the building are devoted. As stated in a leaflet issued by him, the Haus serves:

1. "As a central home for postgraduate medical education and its organizations, namely, (*a*) the Central Committee for Medical Postgraduate Education in Prussia; (*b*) the Federal Board for Postgraduate Medical Education; (*c*) the International Committee for Medical Postgraduate Education.

2. "As a center of instruction for physicians. It contains rooms and laboratories for practical courses in all the sciences auxiliary to modern medicine, such as clinical chemistry, microscopy, bacteriology, roentgenology and scientific photography; also a large and a small theater for lectures.

3. "As a central depot for auxiliary appliances for medical instruction belonging to the 'State Collection of Medical Educational Appliances.' This depot lends free of charge material for teaching purposes for physicians' courses, academic lectures, as also for the instruction of the lay public in

the science of public health, etc. It contains appliances for demonstrations of all kinds, such as diapositives, microscopic preparations, stereoscopic illustrations, charts, atlases, manikins, etc.; the other objects are collected in the following special divisions: plastic department, nursing department and medicohistorical department (with a historical collection of instruments and bandages). Admission to physicians, only, and free of charge. Open as a rule on Wednesday from 10 to 3.

4. "As a place of union for medical science and practical medical technology by means of the 'Permanent Exhibition for the Medicotechnical Industry,' where the doctor will find all the instruments and appliances necessary for the practice of his profession in the departments of surgery, electromedicine, optics, etc.; open to all free of charge, on weekdays (except Saturday) from 10 to 3.

5. "As a place for exhibitions, rooms being placed free of charge at the disposal of special scientific exhibitions for medical instruction.

6. "As a medical information bureau which gives, *gratis*, information concerning all postgraduate courses in the German Empire, as also concerning all other matters touching on the postgraduate education; furthermore, concerning all medical institutions, hospitals, collections, etc., in Berlin with regard to the time and conditions for their inspection; lastly, concerning the possibility of participation in clinical lectures and lecture evenings of medical associations.

7. "As a literary center for all matters concerning postgraduate education, since also the editorial offices of the *Zeitschrift für ärztliche Fortbildung*, published by the German organizations for postgraduate education, are to be found here."

If there was a single reason for the creation of so complete an organization of graduate medical education as has been developed in Germany during the last decade and a half, then there are a dozen equally cogent reasons why the question of the reorganization of postgraduate education in America should be taken up with a view to bringing about a uniform and much extended system. I would suggest that the work already begun in this country under the auspices of the American Medical Association be promptly enlarged and promoted. J. M. Anders, M.D., Philadelphia.

School Athletics and Gate Money

To the Editor:—I was much interested in the editorial on "High School Athletics" (The Journal, Nov. 14, 1914, p. 1765). I should like to see another dealing with the prevention of the evil therein discussed. My own experience, embracing my own student life at school and college, with participation in their athletic activities, three years as teacher in boys' boarding schools, and the observation of sixteen years as a physician sharpened by a never-waning interest in educational subjects, has long since led me to the conclusion that the key to the evil is *gate money*.

Students as individuals do not engage in professionalism, but colleges collectively do so, as surely as do the owners of the baseball league teams. They do not receive their profits in the form of dividend checks, but in the increased attendance and students' fees, and in endowment. The money received is spent on trainers, war material and commissariat, and even on spies. Athletic fields are erected that exceed in seating capacity the Colosseum. Athletics, intended as the young man's sport and recreation, *ut sit mens sana in corpore sano*, has become a commercialized asset, and the candidate for a school or varsity team completely loses his individuality and initiative, becoming the puppet of a professional coach, the tenure of whose office and the size of whose salary depends on the amount of kinetic energy he is able to extract from those under his direction.

Let us imagine, if we can, college athletic contests without a charge for admission. They would cease to be public property, and would be supported by the contributions of the students themselves and of those who are properly interested in their activities. Doubtless there would be less money spent, the public would be deprived of their entertainment, and the college of valuable advertising assets. Sport writers of the daily newspapers would be deprived of much material and the poor trainer and coach would lose their jobs. The contests themselves would lose much of their proficiency. The training table would disappear, and the output of energy would be within the limit of that furnished by the ordinary college diet.

But even these woes might be endured if we had better sportsmanship, and fewer cardiopathies in later life.

B. M. Randolph, M.D., Washington, D. C.

Proper Regulation of School Athletics

To the Editor:—To all those who are interested in the health of schoolchildren, the editorial on "High School Athletics" (The Journal, Nov. 14, 1914, p. 1765) is most welcome. Criticisms of unregulated and unguarded high school athletics are, however, often undeserved. I would join with you in the appreciation of well-conducted physical training work in the gymnasium. There are, however, two forms of athletics: the *intensive*, which is the usual form, in which a few boys in the school are collected on account of their individual powers to undergo a course of training and to represent their school on the athletic field, and the *extensive* form of athletics, in which we endeavor to get all of the student population in healthful athletic training.

In New York City we carry on the intensive form, but have emphasized strongly in recent years the more popular distribution of the benefits of athletics.

Since the organization of the Public Schools Athletic League in 1903, the incorporation of athletics as an official part of the Department of Physical Training, and the establishment of a system of medical examination of all prospective athletes, I have been unable to obtain an authentic record of damage to elementary or high school pupils as a result of athletics. Therefore, I feel constrained to recommend that the weight of medical opinion be directed not against the prohibition of athletics, but toward their proper regulation.

C. Ward Crampton, M.D., New York.
Director of Physical Training.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HOW CHAMPAGNE IS MADE

To the Editor:—Would you kindly tell me what kind of grapes or wine is used in making champagne? I understand that a dry, white wine with a dash of cognac brandy and a little sugar is used. How is it made? J. M. White, M.D., Meridian, Miss.

Answer.—In sparkling wines, as champagne, the primary fermentation is checked at an early stage, so that a secondary or complementary fermentation may occur in the bottle, and cause the sparkle which is characteristic of this class of wine. The juice of black grapes only is used for some kinds, the skins being rejected to avoid the extraction of the coloring matter and tannin. For others red or white grapes are crushed, and, except when colored wines are desired, the juice drawn off at once to prevent the extraction of coloring matter and tannin from the skins and stalks. If a colored wine be desired, the initial fermentation is made before the juice is removed from the crushed fruit. The marc—that is, the crushed skins, etc.—is put under a screw press to remove the remainder of the juice. The latter process is now done in many manufactories by the centrifugalizing machine. The must is fermented in vats for about fourteen days, after which it is racked, the sediment allowed to deposit, and the wine put into casks until winter. It is then transferred to other casks, some finings (gelatin, albumin, kaolin, calcium sulphate, etc.) being added at the same time, and a month is allowed for it to clarify. After this it is blended, some mature wine being put into the mixture, and the amount of sugar in it ascertained. The presence of a definite amount of sugar is necessary to insure the future sparkle. If, therefore, the amount is deficient, some syrup or sugar-candy is added. It is now bottled, and the bottles laid on their sides for a few weeks until the development of carbonic acid gas commences. The wine is then transferred to cellars, some of which are more than 100 feet deep, cut into the chalk, and admirably suited by their uniform temperature to assist in the maturation of the wine. Here it remains three or four years, during which the same changes go on as in the maturation of other wines. A deposit forms, and, as it is desirable to prevent it adhering to the sides of the bottle, it is agitated now and then. After three years the bottles are placed obliquely, so that the deposit may fall on and firmly adhere to the cork. Finally the cork is removed, and the deposit with it; the bottle is filled up with liqueur made of old champagne, brandy and sugar, and it is freshly corked and wired. The secondary fermentation now continues, during which the flavor and aroma of the wine are developed, and the effervescence and sparkle are insured.

CRITICISM OF A PRESCRIPTION

To the Editor:—Is the following prescription a good combination? Such a combination might frequently seem indicated in cases such as painful genito-urinary infection, renal or vesical, and yet the combination changes to a pasty gummy consistency. I wonder whether there is not some chemical change that would alter its efficacy. Please criticize:

Urotropin ....
Sod. Benzoat. ....
Aspirin ....āā ℥i
M. et divide in chart. No. xii.

X. Y. Z.

Answer.—The combination is not a good one for several reasons. Hexamethylenamin (urotropin) and acetyl salicylic acid (aspirin) are chemically incompatible. However, although incompatibility exists in solution, the hexamethylenamin decomposing to yield ammonia and formaldehyd, decomposition would probably occur only to a slight extent in the dry state. Therapeutically, there seems to be no objection to the prescription, if the author sees indications in a case under treatment for the remedies mentioned. If we suppose that hexamethylenamin is used as a urinary antiseptic, its use would probably be indicated for some time. The aspirin presumably is given to relieve pain. It must therefore be considered only as a temporary remedy to be given for a special purpose, and when that purpose is accomplished, should be discontinued. It would better not be combined in the same prescription with the urinary antiseptic lest its purpose be forgotten and the drug be unnecessarily continued. As The Journal has repeatedly pointed out, hexamethylenamin should be prescribed under its proper name, and not by a copyrighted trademark. By calling hexamethylenamin by the proprietary name the physician does not insure that he will get a purer or better drug. He enhances the cost to the druggist, if not to the patient, and prevents the using of any other brand of the pure chemical which the druggist may happen to have in stock.

MILK-SICKNESS

To the Editor:—A family of six acquired milk-sickness which was traced to one cow having the trembles. Five of the family were severely affected, one dying. The father of the family was not affected by the disease. All of them excepting the father drank of the milk while it was sweet. The father used it only after it was churned, as butter and buttermilk. Please answer these questions as fully as possible:

1. Does the liberation of the acids formed by the transformation of sweet milk to buttermilk destroy the poison of milk-sickness?

2. Milk-sickness is evidently a germ disease. Tell what you can concerning its etiology.

3. What other toxemias are characterized by severe subnormal temperatures?

R. L. Talley, M.D., Bible Grove, Ill.

Answer.—1. Apparently not. There are many instances on record in which butter has been held responsible for the conveyance of milk-sickness. Probably in the case you mention the difference may have been quantitative—a smaller amount of buttermilk being used, so that the size of the dose was less than in the case of those drinking fresh milk.

2. We may refer you to a paper by Jordan and Harris appearing in the *Journal of Infectious Diseases*, September, 1909, vi, No. 4. You can probably obtain a reprint by addressing the authors.

3. Many non-infectious toxemias are associated with a low temperature, as seen in the collapse after organic poisoning, especially when there is vomiting and loss of food.

ARTICLES ON TETANUS

To the Editor:—Please advise me of any recent developments in tetanus.

C. A. Hofer, M.D., Metuchen, N. J.

Answer.—The following is a list of recent articles on this subject:

The Administration and Value of Tetanus Antitoxin, editorial, The Journal, Aug. 30, 1913, p. 687.
Jones, F. R.: Tetanus, *Semana méd.*, Sept. 26, 1912; abstr., The Journal, Nov. 30, 1912, p. 2014.
The Value of Tetanus Antitoxin, correspondence, The Journal, Dec. 7, 1912, p. 2084.
Irons, E. E.: Treatment of Tetanus by Antitoxin, The Journal, June 27, 1914, p. 2025.
The Serum Treatment of Tetanus, editorial, The Journal, April 11, 1914, p. 1174.
Ashhurst, A. P. C., and John, R. L.: Rational Treatment of Tetanus with Report of Twenty-Three Cases, *Am. Jour. Med. Sc.*, June and July, 1913.
Holman, C. J.: Magnesium Sulphate in Tetanus, *St. Paul Med. Jour.*, June, 1911; abstr., The Journal, July 1, 1911, p. 45.
Parker, George: Treatment of Tetanus with Magnesium Sulphate, with Report of Three Cases, The Journal, June 8, 1912, p. 1746.
Kocher, T.: Magnesium Sulphate in Tetanus, *Cor.-Bl. f. schweiz. Aerzte.*, 1912, xlii, No. 26, abstr., The Journal, Oct. 19, 1912, p. 1496.
Kocher, T., and Arnd, G.: Cure of Tetanus by Magnesium Sulphate, *Cor.-Bl. f. schweiz. Aerzte.*, 1913, xliii, No. 4, abstr., The Journal, March 29, 1913, p. 1036.

TUBERCULIN IN DIAGNOSIS

To the Editor:—1. Is tuberculin, given hypodermically, used as a diagnostic test for tuberculosis by the best clinicians at present?

2. Would it be advisable to give tuberculin for diagnostic purposes in a patient having night-sweats, in whom there is no discoverable cause for them?

Answer.—1. Yes. Koch's old tuberculin is used for diagnostic purposes by many of the best physicians. Some, however, regard its use as being attended by a certain risk of causing a flare up of a local focus, a danger that certainly attends the use of large doses. When used, the initial dose should be small, perhaps not more than 0.1 milligram. In the event of negative results the dose may be increased by 0.5 mg. or 1 mg. every two or three days up to a point at which even 5 mg. are given. Careful temperature records should be taken at short intervals after the injection. Otherwise no interpretation of a reaction is possible. In instances in which fever already exists, the reaction is difficult of recognition. It should always be kept in mind that a positive reaction, though showing the existence of tuberculosis, does not necessarily mean that the symptoms for which an explanation is sought are produced by the tuberculosis process that is somewhere in the body.

2. Tuberculin would probably be safe in the case described and might help in diagnosis.

CUSTOM OF YOUNGER PHYSICIANS CALLING ON OLDER

To the Editor:—In a recent discussion, the question was brought up as to whether it was correct for the new practitioner in a town to call on his fellow practitioners first, or whether they should call on him first. Can you put me right on this?

R. L. K.

Answer.—The Journal has replied to this question before, as follows: "It is an accepted custom for young physicians and newcomers to call on the older physicians and those of longer residence in the locality. It is a mark of courtesy and respect due from one locating in a new place. He thus announces his arrival and his desire to be recognized in professional circles and friendships." This custom must not be confused, as it appears sometimes to be, with that which governs social relations when a family takes up its residence in a new locality.

ACCIDENTS TO UNSUITABLY EMPLOYED EPILEPTICS

To the Editor:—I am preparing a paper on "Accidents Due to Epileptics Being Unsuitably Employed," or being in unsuitable places at the time of seizure, to be illustrated by photographs of patients showing resultant mutilations.

Will you kindly put me in touch through the pages of The Journal with physicians having had such patients, who would be willing to send photographs showing result of such accidents? The physicians would get full credit, names of patients would not be mentioned, and photographs would be returned.

I feel the importance of such a paper of warning on account of the number of crippled epileptics, often preventable cases too, who frequent my consulting rooms.

Matthew Woods, M.D., 1402 Spruce Street, Philadelphia.

Arizona April Report

Dr. John Wix Thomas, secretary of the State Board of Medical Examiners of Arizona, reports the written examination held at Phoenix, April 7, 1914. The total number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 13, of whom 8 passed, including 2 osteopaths, and 5 failed. Licenses were issued to 4 candidates who were in active practice prior to the adoption of the law. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Indiana Medical College	(1906)	77.8
University of Maryland	(1913)	76.7
Tufts College Medical School	(1903)	75.3
Washington University	(1907)	80
Medico-Chirurgical College of Philadelphia	(1913)	76
Royal College of Physicians, Edinburgh	(1882)	68.6*

* Ten per cent. credit allowed for years of practice.

FAILED

College	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1913)	72.8
Hospital College of Medicine, Louisville	(1904)	40.3
Baltimore Medical College	(1913)	70.3
Barnes Medical College	(1902)	61
University of Tennessee	(1901)	53.9

Colorado July Report

Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, reports the oral and written examination held at Denver, July 7, 1914. The total number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 13, all of whom passed. Eleven candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Colorado (1914) 82, 82.9, 83.5, 84.3, 84.4, 85.1, 85.9, 85.9, 87.9, 91.4.

Book Notices

Public Health Laboratory Work. By Henry R. Kenwood, M.B., F.R.S., D.P.H., Chadwick Professor of Hygiene and Public Health, University of London. Sixth edition. Cloth. Price, 10 shillings net. Pp. 413, with illustrations. London: H. K. Lewis, 1914.

In this edition of Kenwood's book the summary of public health bacteriologic work, which was formerly included, has now been omitted, in order to keep the volume within the compass of a handy laboratory guide. It is devoted entirely to the chemical side of public health laboratory work. The author believes that the needs of the public health student in bacteriology are now fully provided for by several excellent laboratory books. The idea is a good one, and if authors in general were more careful to prevent duplication of material when many good text-books already exist, there would not be so many incomplete and superficial text-books on the market. In an introductory note the author discusses the various apparatus used for the examinations outlined in the rest of the book, and supplements it with tables of weights and scales. The first part of the book deals with the chemical, microscopic and physical examination of water for public health purposes; the second to an analysis of sewage; the third part to soil; the fourth to air; the fifth to food, and the sixth to disinfectants. It is complete and up to date. Every phase is taken up simply and with complete directions for making the necessary tests. In the part on food examination all the common articles of diet are considered. With this book as a guide the public health laboratory worker will be able to carry out examinations for adulteration and standardization of any products which may be brought to him for this purpose. There are eighty-seven illustrations and several large plates, which add to the complete nature of the book.

Diagnosis of the Malignant Tumors of the Abdominal Viscera. By Rudolph Schmidt, Professor of Medicine in the University of Innsbruck. Authorized English Version by Joseph Burke, Sc.D., M.D., Attending Surgeon, Buffalo Hospital of the Sisters of Charity. Cloth. Price, $4. Pp. 361. New York: Rebman Company, 1913.

This work is divided into three parts. In Part 1, consisting of fifty-nine pages, are discussed the general methods of examination in abdominal conditions, general symptomatology and such etiologic factors as may be of importance in the taking of histories of malignant growths. Part 2, of 110 pages, is special and in it are discussed growths of the separate organs and regions. Part 3, of 187 pages, is devoted to case histories. The author's endeavor is to present the subject in a practical and clinical manner. Special stress, therefore, is laid on the early symptoms and on a careful and painstaking history, so conducted as to bring out the essential points. The case histories are all arranged according to a definite plan, which materially facilitates comparison and enables one to grasp more easily the relative importance of any particular factor. The arrangement of the history taking is as follows: (1) ancestry and relationship; (2) congenital peculiarities, metabolic dieases, etc.; (3) previous infectious diseases; (4) previous history of the digestive tract; (5) other previous history; (6) initial symptoms and further course; (7) objective symptomatology; (8) dates of events and duration of the disease, and (9) findings at necropsy or laparotomy. After each history is a brief critical note on the essential facts as brought out in that particular case. The author is rather conservative regarding the value of the Roentgen ray in the diagnosis of these conditions. He says: "With respect to the value of radiological examination in regard to abdominal diseases in general and gastro-intestinal affections in particular, it would seem that at the present time there are prevalent some rather exaggerated notions not only among the laity but also in the medical profession. The fact must not be overlooked that as sources of error in methods of examination radiology ranks among those that head the list." The author is very careful in his observations and exacting in his technic, yet some of the exceedingly delicate tests are often of scientific rather than of clinical value, which fact is recognized by the author, and he says: "Whoever for example utilizes large amounts of feces to obtain blood-coloring matter will have positive results oftener than he, as I recommend it, who carries out the test in a coarser way. To search for the smallest traces of blood is senseless and to no purpose." The translation is at times quite literal to the extent of making what in English are very cumbersome sentences, but there is no difficulty in arriving at the intended meaning.

The Diagnosis and Treatment of Digestive Diseases. A Practical Treatise for Students and Practitioners of Medicine. By George M. Niles, M.D., Professor of Gastro-Enterology, Atlanta Medical College. Cloth. Price, $5 net. Pp. 507, with 87 illustrations. Philadelphia: P. Blakiston's Son & Co., 1914.

This book is of much interest, especially because it was written by one living in the South, whence few medical monographs of its size come. The author states in the preface that he has attempted a concise, easily intelligible description of the diagnostic methods employed by stomach specialists and an exhaustive discussion of general and special therapy applied to diseases of the stomach and bowels. He has succeeded in making easily intelligible descriptions, but has not been concise. His best work is in the discussion of treatment. While the student or practitioner can gain many ideas in regard to diagnostic methods and treatment from this book, it cannot take the place of more authoritative or encyclopedic works on this subject as, for example, those of Boas, Einhorn or Hemmeter. A sufficient number of pages are devoted to the chemical and physical examination of the stomach and intestines and their contents, but the consideration of these subjects is not sufficiently detailed, and various methods are not sufficiently adjudged or valued. Too little is said of Roentgen examinations which have become important aids to diagnosis. Much is said about treatment, and most of it is judicious and commendable. Chapters are devoted, among other subjects, to local treatment of the stomach, local treatment of the intestines, hydrotherapy and psychotherapy. Only the commonest individual gastric and intestinal diseases are considered at all. The subject of the symptomatology and diagnosis of these is so briefly and unsatisfactorily considered that it is doubtful if a student without the aid of other books could make a diagnosis; certainly he would not know the natural course and fully comprehend the symptomatology of the diseases. The subject of the treatment of these special diseases is for the most part sufficiently full and detailed.

Clinical Examination of the Blood and Its Technic. A Manual for Students and Practitioners. By Prof. A. Pappenheim, Berlin. Translated and Adapted from the German by R. Donaldson, M.A., M.B., Ch.B., Pathologist Royal Berks Hospital, Reading. Cloth. Price $1.25 net. Pp. 87, with 5 illustrations. New York: William Wood & Co., 1914.

"This little book differs from all others that treat of the blood in so far as it deals only with what is absolutely essential and of first importance in clinical methods of blood examination. Of the three cardinal lines of blood investigation (viz., staining, counting of cells and hemoglobin estimation) only those methods have been described which have been definitely proved of value. Coupled with the description of methods, the respective features of normal blood have been briefly discussed; while, in addition the most important facts in the semiology, necessary for a proper understanding of pathologic conditions, have been dealt with."

Owing to the recognized position of Pappenheim in the field of hematology, it is interesting to note that he recommends the combination of the May-Grünwald stain with the Giemsa stain as the most serviceable panoptic blood stain at our disposal. For hemoglobin determinations he recommends Sahli's hemoglobinometer as the most practical clinical instrument. This little work needs no recommendation beyond the name of its writer to all who wish a clear and concise outline of the essentials of hematology. While the two plates of the various types of red and white cells found in the blood are adequate for the size of this work, yet they are not sufficiently comprehensive for those who may wish to make a more elaborate study of the blood. For the latter workers Pappenheim's atlas is intended.

Manual of Military Hygiene for the Military Services of the United States. By Valery Havard, M.D., Colonel, Medical Corps, United States Army, Retired. Published under the Authority and with the Approval of the Surgeon-General, U. S. Army. Second Edition. Cloth. Price, $5 net. Pp. 786, with 258 illustrations. New York: William Wood & Co., 1914.

The author says it has been found that soldiers on the march or in hard fighting campaigns, even though on scant rations, with worn-out clothing, and subjected to great exposure, are less subject to infectious diseases and sickness than when they are in permanent or semipermanent camps where they attempt to make themselves comfortable and devote much of their time to eating, sleeping and diverting themselves. Hard work and plain fare are good preservatives against disease. The main purpose of the principles and the purposes of military hygiene, therefore, is to protect the soldier against himself, his habits and his surroundings while in camp or barracks, where he spends the major portion of his time. These principles and purposes are clearly set forth in the book as they apply to soldiers on land and the naval forces, and as they relate to service in tropical and far northern climates, together with a discussion of infectious and parasitic diseases, the nutritive value of the various foods composing army rations, etc., all according to the latest ideas on these topics. The book is abundantly illustrated and contains a list of the more recent works on hygiene. At a time when military matters are actively to the fore, this book is timely, interesting and valuable.

Local Anesthesia. By Dr. Arthur Schlesinger. Translated by F. S. Arnold, B.A., M.B., B.Ch. Cloth. Price $1.50 net. Pp. 211, with 22 illustrations. New York: Rebman Company, 1914.

This is a handy little volume devoted to the practical discussion of local anesthesia with only casual references to theory. A brief historical survey precedes a splendid exposition of the physical principles of local anesthesia. Cocain is the author's choice of anesthetic and his remarks on cocain poisoning ought to be of value to any one who makes use of cocain for producing local anesthesia. Brief mention is also made of other substances used for this purpose. Quinin and urea hydrochlorid are not even mentioned. The adjuvants in local anesthesia, especially the adrenal preparations, are discussed thoroughly. Individual chapters are devoted to the methods of local anesthesia, such as cold, infiltration anesthesia, nerve blocking and blood-vessel anesthesia, general technic, and their application in operations on the various parts of the body. For review purposes or to get the author's views on the subject, the book fills a place; but if one wishes to get a more comprehensive view of the whole subject of local anesthesia, other, larger books must be consulted.

Spectrum Analysis Applied to Biology and Medicine. By the Late C. A. Macmunn, M.A., M.D. With a Preface by F. W. Gamble. Cloth. Price, $1.75 net. Pp. 112, with 21 illustrations. New York: Longmans, Green & Co., 1914.

Although spectrum analysis is often the most certain, if not the most delicate method of detecting the presence of many substances of great medical importance, nevertheless, very little use is made of such examinations by the practitioner, or even by the skilled laboratory worker. For this reason the appearance of this little posthumous monograph of Macmunn must be considered very timely. Simple perusal of this work will reveal many applications of spectrum analysis which may be employed as direct aids in diagnosis. The subject matter is divided into a preface and nine chapters, treating of the principles of spectrum analysis and their application to the study of various pigments of importance in general biology and medicine. Especial attention is given to the characteristics and differentiation of hemoglobin and its derivatives as well as of the biliary and urinary pigments. An extensive bibliography greatly enhances the value of the monograph. The book may be recommended as an extremely useful and valuable work for the general practitioner and, especially, for the laboratory investigator, who should employ the methods of spectrum analysis to a much greater extent than is customary.

Trachoma and Its Complications in Egypt. By A. F. MacCallan, M.D., F.R.C.S., Director of Ophthalmic Hospitals, Egypt. Cloth. Price, $2.50. Pp. 74. New York: G. P. Putnam's Sons, 1913.

In the home of this ancient disease the author has had abundant opportunity to study it in its various aspects. The clinical material on which the monograph is based embraces a total attendance in 1912, of 341,211 outpatients and a total number of 21,315 operations performed. More than 6,000 patients with trichiasis were turned away because of lack of equipment, but by the end of the present year there will be eight permanent and six traveling hospitals fully equipped, so that all who apply for treatment will probably be accommodated. The author has not attempted to give a complete description of all the methods of treating trachoma, but rather to give a simple description of the disease as it is encountered in the East, and of its treatment as carried out in the Egyptian ophthalmic hospitals. Following a brief historical sketch, the major portion of the book deals with trachoma in its various clinical phases, pathology, diagnosis, complications, sequelae and treatment. Statistics are given which emphasize the high percentage of cases of blindness resulting from trachoma.

Die Aeussere Sekretion der Verdauungsdrüsen. Von Dr. Med. B. P. Babkin, Professor der Physiologie am Institut für Land- und Forstwirtschaft zu Nowo-Alexandria. Paper. Price, 16 marks. Pp. 407, with 29 illustrations. Berlin: Julius Springer, 1914.

This work, with numerous tabulations and curves derived from experimental studies, deals with the gross and microscopic anatomy of the several digestive glands, but more particularly with their innervation, the mechanism of their operation and the work they perform. The fact that Babkin was for ten years associated with Pawlow as assistant sufficiently indicates the character of the themes discussed. Such questions as enzyme action and the chemistry of digestion are touched on "only in so far as has been found unavoidable for a proper differentiation of the several external secretions." The book collects and presents for the first time in compact form all of the later studies of the Pawlow laboratory together with a general review of the literature bearing on these subjects. The latter is extensive if not complete. It will be found valuable to American readers because of its exhaustive treatment of the not easily available Russian publications.

Beiträge zur Frage nach der Beziehung zwischen klinischem Verlauf und anatomischem Befund bei Nerven- und Geisteskrankheiten. Bearbeitet und herausgegeben von Franz Nissl. Volume 1, Part 2. Zwei Fälle von Katatonie mit Hirnschwellung. Paper. Price, 2.80 marks. Pp., 112, with 48 illustrations. Berlin: Julius Springer, 1914.

It is the author's aim to publish the complete case histories of nervous and mental cases, their post-mortem findings, including microscopic examination of tissues, with a view of gaining more definite knowledge of the anatomic basis of nervous and mental disease. The issue before us contains the complete report, both clinical and anatomic, of two cases of catatonia, which constitutes interesting reading. Asylum physicians and neurologists will find much of value in the perusal of the histopathologic descriptions and interpretations of these two cases.

Surgical Diseases and Injuries of the Genito-Urinary Organs. By J. W. Thomson Walker, M.B., G.M.Ed., F.R.C.S., Hunterian Professor of Surgery and Pathology, Royal College of Surgeons of England. Cloth. Price $7. Pp. 879, with 324 illustrations. New York: Funk and Wagnalls Company, 1914.

This book, offered as a text-book for the general practitioner and the student, embodies a survey of the literature, together with much of the extensive personal experience of the author. Although containing numerous valuable cystoscopic and roentgenographic plates, in its discussion of surgical technic it seems lacking in adequate illustrative material and the detailed description which enables the student to carry out the procedures recommended. Accordingly the book may be selected as a reference work of great value but would seem to fall short of the value placed on it by the author as a text-book.

Medicolegal

Injunction Granted Against Annoyances from Hospital

(Kestner et al. vs. Homeopathic Medical and Surgical Hospital (Pa.), 91 Atl. R. 659)

The Supreme Court of Pennsylvania affirms a decree enjoining the defendant hospital, of Reading, from using its building as a hospital until the emergency operating room should be removed to some other part of the building, and also restraining the defendant from permitting persons occupying rooms in the hospital from throwing refuse matter on the complainants' premises. The court says that it was found that the complainants' building had twenty-one windows and nine doors facing the hospital, the windows and all the doors, except two, being from 9 to 12 feet distant from the hospital. The rooms facing the hospital included the parlor, living room, dining room, kitchen, pantry and summer kitchen on the first floor, and sleeping rooms on the second floor, the dining room being less than 13 feet from the emergency operating room. A wooden fence about 9 feet high separated the two yards. Noises came to the complainants' property from the hospital, mostly from the emergency operating room, almost daily, and at all hours of the day and night. The trial judge also found that the hospital was equipped with the modern surgical and medical appliances, employed sufficient physicians and nurses, and used with promptness approved methods of relieving patients from pain and suffering and of preventing the outbursts complained of. Also that shrieks and screams were of no greater frequency than those emanating from well-regulated hospitals treating the same number of patients; that such noises are bound to occur wherever sick or injured persons may be, and particularly in a hospital where a large number of persons are brought, or come, for medical and surgical treatment. The court holds that, under the authorities, the complainants were clearly entitled to equitable relief, such as was granted.

Requirement in Prosecution for Practicing Medicine Without Authority

(Feige vs. State (Okla.), 142 Pac. R. 1044)

The Court of Criminal Appeals of Oklahoma reverses a judgment against Feige, who had been convicted of practicing medicine without first having procured a proper certificate as provided by law, and had been fined, the case being remanded to the county court with directions to cause a proper information to be filed and the trial proceeded with as provided by law. The court says that, under Section 6910 of the Revised Laws of Oklahoma of 1910, a person who prescribes or administers any drug or medicine, included in the materia medica, for the treatment of diseases, injuries, or deformities of human beings is subject to prosecution. Likewise, one who is not licensed to practice medicine as provided by law can be prosecuted for publicly professing himself to be a physician and prescribing for the sick. The information, however, should be direct and certain as to which of these provisions the state is prosecuting under.

The information in this case charged that Feige did, in Oklahoma County, on May 28, 1912, commit the crime of practicing medicine without a license in that he did then and there unlawfully, etc., practice medicine without first having obtained from the state board of medical examiners a certificate as provided by law, entitling him to practice medicine within the state of Oklahoma, in that he did then and there unlawfully and willfully prescribe for, and furnish medicine to, and treat one Cornelius A. Prohl, for compensation, contrary to the form of the statutes, etc. The information on its face was wholly insufficient. It should have charged, among other things, the administration of some drug included in materia medica in the treatment of diseases, etc., or that the accused publicly professed to be a physician and prescribed for the sick.

This prosecution was meritorious, but this court cannot overlook a fundamental right. The trial court should have arrested the judgment and directed the prosecuting attorney to file a proper information, when a motion was made in arrest of judgment, as an information which fails to state a public offense under the statute is subject to attack by a motion in arrest of judgment.

Miscellany

Trachoma in the Mountain Sections of Eastern Tennessee and Northern Georgia

A survey of the prevalence of trachoma in the mining and mountain rural sections of the Appalachians traversing Tennessee and Georgia, made under the direction of the Surgeon-General of the United States Public Health Service and in cooperation with the state boards of health of Tennessee and Georgia, is described in *Public Health Reports* for September 18. The work was begun in eastern Tennessee in December, 1913, and concluded in northern Georgia in April, 1914. The object was not to detect every case of trachoma, but to outline the areas of infection by examination of a representative number of persons in each county, to devise means for its control and ultimate eradication, and to arouse the medical profession and the public to a sense of its importance.

It was found impracticable to conduct house-to-house inspections, because of the time consumed and the impossibility of finding adults willing or able to spare the time to be examined. The examinations were therefore confined almost exclusively to schoolchildren. In Tennessee 130 schools distributed through thirty-one counties were visited and over 15,700 pupils and instructors examined; 341 cases of trachoma were found. In northern Georgia eighty-four schools distributed through twenty-five counties were visited and over 7,800 pupils and instructors examined; seven cases of trachoma were found. The attention of county health officers and local physicians was drawn to the disease wherever it was found. Only positive cases presenting clinically characteristic connective tissue hyperplasia with lymphoid cell proliferation, destruction of the overlying conjunctiva and scar tissue formation were considered as trachoma, suspicious cases (probably incipient trachoma) were not included in the statistics. The type of trachoma found in Tennessee and Georgia was, in the main, less severe than that found by Surgeon McMullen in the survey of Kentucky. Negroes, though not immune, appeared to be less susceptible to infection than whites. The foreign population of the state is small and this element is believed to be a negligible factor in the spread of the disease.

Physical Condition of Chinese Students

The Yale Mission, Changsha, China, has examined all the students of the school under the same system as that used at Yale. The percentages of medical examinations were the following: The general physical condition of 25 per cent. was poor, while that of 53 per cent. was only fair. In muscular development the percentages were: poor, 39 per cent.; fair, 41 per cent.; good, 20 per cent. Nutrition and fatty tissue were subnormal in 27 per cent. and only fair in 46 per cent. Examinations for digestion showed 33 per cent. poor, 25 per cent. fair and in 74 per cent. the presence of Ascaris eggs. Unhealthy conditions in the respiratory system were noticeably prevalent. The vision of 40 per cent. was defective. In the circulatory system a thickening of the vessels was noticeable in 49 per cent., which is abnormal for an average of 18 years, 6 months. Thirteen per cent. had some enlargement of the heart, while 20 per cent. had either murmurs, or other signs of irritability. Beginning at 5 feet 2 inches, comparisons were made between the Yale students and those of the Chinese mission at nine intervening heights up to 5 feet 8½ inches and the differences in measurements for all heights were averaged. Chinese students average less than Yale students in most measurements. The results indicate that the physical condition of the Chinese people generally is defective.

NEW YORK NEUROLOGICAL SOCIETY

Meeting held Oct. 6, 1914

The President, Dr. Smith Ely Jelliffe, in the Chair

Double Cervical Rib Nerve Symptoms

Dr. S. P. Goodhart and Dr. Alfred S. Taylor: The patient was a woman, aged 30. Symptoms referable to the cervical ribs dated apparently from the eighth year. During her eighteenth year she noticed that certain movements necessitating placing the arm behind her caused flexor spasm of the muscles of the forearm and hand. When the patient was 23 years old she observed weakness in the grasp and in the finer movements of the left hand, followed by progressive atrophy of the small hand muscles, both the thenar and hypothenar surfaces being involved. Soon afterward a coldness of the left upper extremity, particularly from the elbow to the finger tips, was at times felt subjectively and could be demonstrated objectively. Examination revealed areas of hypesthesia and hyperalgesia distributed irregularly over the left forearm and hand. These areas varied and finally disappeared, leaving as the only sensory disturbance an area of hypesthesia for all forms of sensation in that part of the forearm and hand corresponding to the inner cord of the brachial plexus, particularly the ulnar distribution. At this time the left hand presented an appearance of the typical *main en griffe*, and some atrophy of the pectoral muscles was noted. Cervical ribs were now recognized. About 1907, involvement of the brachial plexus on the right side developed. Within the next few months numbness of the entire right leg and pains in the calf muscles were experienced. In May, 1908, the patient submitted to an operation for the removal of both false ribs. The subclavian artery crossed the first rib anteriorly and below the distal end of the cervical rib, the roots of the plexus lying over the false rib. The eighth cervical and first dorsal roots were undergoing the greatest tension and pressure. Immediately following the operation there was a paralysis of nearly all the muscles and the sensory surfaces supplied by the plexus on both sides. In the course of a week, motion and sensation began to return, and the improvement, though slow, was constant. About one year after the operation there was still considerable atrophy and very slight sensory changes over the inner surface of the forearm. At the present time, about six years after the operation, there is marked improvement in the muscle supply.

Spinal Hematomyelia of the Hemiplegic Type

Dr. Frederick Tilney and Dr. C. L. Nichols, Brooklyn: The patient, a man aged 28, while diving in shallow water, fell into the water almost perpendicularly. He thought he struck the sandy bottom on his head, neck or on the vertex, posteriorly. He had to be dragged from the water and was found to be suffering from a complete paralysis of the right upper and lower extremities, and an awkwardness in the use of the limbs on the opposite side. There had been no loss of consciousness and he was perfectly oriented. His head was numb and the whole body felt bruised and sore. The pain was most severe over the right shoulder, extending down the arm and forearm. There were no spasmodic movements in this area. Several hours after the injury he still complained of the sensation of having been bruised, especially over the right clavicle and upper chest. The right pupil was smaller than the left: both responded to light and accommodation. The heart's action was slow and regular and the sounds of good character. The pulse was of fair quality and volume. The abdomen showed no abnormalities. No reflexes could be elicited on the right side, and sensation was absent, with the exception of variable areas of response to pin prick. The field of vision was undisturbed. The fundus showed slight congestion of the nerve; the margin was not well defined and the vessels were slightly engorged, evidencing some pressure. The hearing was affected on both sides. One week later, the anisocoria was still more apparent. Two weeks later he was allowed to sit in a chair and ten days after that he was able to walk.

On the first day after his discharge he had an agonizing pain on the right side of the head over an area extending from the forehead along the vertex in the median line to the occiput. This persisted for two hours. A similar attack, less severe, followed a week later. After the patient had been seated for any length of time he became stiff in the right hip, and on arising had a dull pain extending from the lower part of the spine forward into the right groin. He also complained of a similar pain extending from the cervical spine to the right shoulder. There were no urinary symptoms. The bowels had moved regularly ever since the accident. Examination at the present time shows a flaccid paralysis of the right upper extremity and a spastic paralysis of the right lower extremity. The tendon reflexes on this side were greater than those on the left, while the abdominal, epigastric and cremasteric reflexes were absent. The latter were present on the left side. The Babinski was positive on the right side, and there was permanent clonus in the ankle. In eliciting the triceps reflex on the right side, percussion on either the tendon or the muscle produced flexion of the forearm instead of extension. The roentgenogram showed a fracture of the sixth cervical vertebra.

Case of Spinal Hematomyelia: Brown-Séquard Paralysis

Dr. Tilney and Dr. Nichols: The patient, a boy of 20, fell a distance of about 10 feet, striking the ground on his chest without losing consciousness. None of the extremities could be moved voluntarily. The pupils were equal, and reacted naturally. The pulse was regular and of good volume. The heart sounds were normal. The respiration was chiefly abdominal, the chest moving very little. The arms could be moved, though very slowly and with great difficulty. The fingers were held in a position of partial flexion, with no power either to flex or extend them. The knee-jerk was absent on the right side and present on the left. The Babinski could not be elicited. The toes of the right foot were red; those of the left were pale, and the surface temperature of the left lower extremity was diminished. There was an absence of the cremasteric reflex. There was tactile anesthesia in both lower extremities and in the trunk up to the second interspace. Pain sense was absent in the left leg and as far up as the third rib, but present over a corresponding area on the opposite half of the body, where it was apparently hyperacute. The temperature discrimination was entirely absent on the left side to a level a little below the clavicle, but was present on the right side, although the response to heat was not so good as to cold. There were sticking pains in the right leg, and the patient felt as though there was a strap around it and another around the shoulders, each being tightened in an opposite direction. There were fibrillary tremors on the left side. Priapism was present during the examination. Catheterization showed no evidence of hematuria. One month later the patient had a slight power of flexion of the left fingers. Sensation was unchanged. The pupils reacted promptly, but were unequal. The patellar reflex on the right side was exaggerated. One week later there was an involuntary urination. Up to that time catheterization had been necessary, but from that time on the control of the bladder was normal. The lesion in this case was located in the upper cervical region. The roentgenogram demonstrated absence of fracture or dislocation.

DISCUSSION

Dr. William M. Leszynsky: In cases of traumatic lesions of the cord the question of operation usually comes up, and I have been guided largely by the clinical manifestations. If it can be shown that we were dealing with a fracture dislocation producing crushing of the cord, an operation is inadvisable. When blood is found in the cerebrospinal fluid, the hemorrhage is usually subdural. When the cerebrospinal fluid is clear, as in hematomyelia, operation is not indicated. In many of these cases the early residual symptoms often become permanent, their severity depending on the amount of damage done to the cord. It is impossible to give a positive prognosis as to the ultimate outcome.

Dr. Benjamin Rosenbluth: I have seen four cases of injury of the cauda equina, and the result of operation was most encouraging.

Dr. J. F. Terriberry: In cases of hemorrhages within the cord, little can be expected from operative interference. These cases, as a rule, do much better under proper general care, with subsequent reeducation of the lost muscular function if the residual symptoms demand it. The fact should be borne in mind that this loss of function is sometimes attributable to a stiffening of the joints of the hands and fingers, which often does much to retard the reparative process, and it was only with care and perseverance that one could get the most out of these cases.

MEDICAL SOCIETY OF VIRGINIA

Annual Meeting, held in Washington, D. C., Oct. 27-30, 1914

The President, Dr. Southgate Leigh, Norfolk, in the Chair

Officers Elected

The following officers were elected for the ensuing year: president, Dr. Samuel Lile, Lynchburg; vice-presidents, Drs. Samuel B. Moore, Alexandria, Joseph T. Buxton, Newport News, and Dr. J. W. Preston, Roanoke.

Place of meeting, session of 1915, Richmond.

SYMPOSIUM ON GOITER

Causes of Thyroid Diseases

Dr. R. M. Taliaferro, Lynchburg: The endemic form of goiter is believed to be the lack of something, mineral or albuminoid. It is asserted that the addition of Lugol's solution to the water-supply will cure. No country is exempt. It is closely associated with the generative organs in females; puberty, menstruation, menopause and especially pregnancy especially seeming to have some influence. Various toxemias have been associated, and there seems to be an effort of the body to have the metabolism meet the toxins.

Pathology and Symptoms

Dr. J. C. Flippin, Charlottesville: The high percentage of iodin in the thyroid is very important. The thyroid of the fetus and the suckling animal probably contain no iodin. The iodin percentage is below normal in the diseased gland, while in exophthalmic goiter it is as much as 80 per cent. above normal. A certain relation to the other internal secretions exists. The epinephrin content is increased in exophthalmic goiter.

Medical Treatment

Dr. George W. McAllister, Hampton: Iodin in the sporadic form gives the best results. No one factor is of so much importance as rest in the open air. I have been disappointed in the action of the extracts of ductless glands. Parathyroid sometimes controls the tremor. As to the benefit from the use of serums from thyroidectomized animals, testimony is conflicting.

Surgical Treatment

Dr. J. S. Horsley, Richmond: Surgical treatment is of value in simple cases, malignant cases and in hyperthyroidism. In the hands of a competent man the mortality in simple cases should be less than 1 per cent. Surgical treatment is now practically limited to tying one or more arteries or to thyroidectomy. Two rules are of prime importance: Avoid exciting the patient, and use careful manipulations.

DISCUSSION

Dr. Tom Williams, Washington, D. C.: Enlarged thyroids may be due to toxemias, the result of multiple infections. I do not believe that it is always wise to remove the gland. The Roentgen ray inhibits the action of the gland and renders the patient comfortable.

Dr. Allison Hodges, Richmond: In the majority of cases we are wasting time by using medical measures. Of twenty-two patients only four were definitely improved in from three to eight weeks. Of the other patients twelve were operated on by surgeons, and eight were cured while four were partly cured. I am not anxious to submit these cases to the surgeons, but we should do what is best. The surgical cases in which there was no improvement were those in which excessive anxiety was associated. Do not protract medical treatment.

Calcification and Ossification of Walls of Heart

Dr. Harry T. Marshall, University: A man died of heart failure. During life he had a murmur and myocardial insufficiency. The heart was much enlarged, hypertrophied to the left and both dilated and hypertrophied to the right. The left auricle was encased in a firm calcified sheath, which could not be collapsed by pressure. The muscle was unaffected. The endothelium was thickened from 1 mm. to half an inch, with ridges on the lining looking like loose bone. Lacunae and osteoblastic cells were to be seen, and unmistakable bone-marrow.

Psychoneuroses in Their Relation to Chronic Infections

Dr. Allison Hodges, Richmond: Physicians do not always respect such influences as heredity and environment. A number of morbid conditions are apparently functional. Study the personal abnormalities of the patient. They have either a psychogenic or a somatic basis. In all cases that I have records of there is the element of heredity. There is physical suffering in the psychoneurotic, properly speaking. I have not found organic troubles to be a cause as often as I had anticipated. Woman is especially apt to think the uterus is the cause, and if this is so stated by the physician she is confirmed in her distress. Urethra and seminal vesicle disease in the male is likewise a source of disturbance. Gastro-intestinal disturbances are an unquestionable cause of psychoneuroses. Gall-bladder infections play only a minor part. The large majority of these troubles are purely in the brain. Rational treatment is the removal of the cause.

Use and Abuse of Pituitary Extract in Labor

Dr. Virginius Harrison, Richmond: The forceps is not abused so much as formerly. Posterior lobe extract has been brought forward as a substitute for forceps. This drug has been standardized. This is important, for we may be using 1 or 2 mg. to the dose. If much chloroform is given before its administration, the effect is lessened, but if chloroform succeeds it the effect is increased. I have never seen it take more than six minutes before having effect, and this effect lasts from thirty to sixty minutes. If necessary, try the second dose in one hour; if no results, then use other methods. Twenty per cent. of my patients had bowel action without using a laxative. One patient had marked angina pectoris in two minutes; it passed off quickly. One child had convulsions, but they may have been due to injury to the head. It made a good recovery. The contra-indications are normal labor with good pains, high blood-pressure with arteriosclerosis, undilated cervix, and tumors. It will not start pains but will intensify those present. It shortens the third stage of labor, and prevents hemorrhage when given after the delivery of the child. It is capable of doing great damage to the soft parts and to the child. Its action is very prompt and the doctor should be prepared for emergency. Uterine inertia is the thing that will make us use it most frequently. It will convert a high forceps case into a low forceps case. Engagement should occur before it is given. It makes instrumental work easier. It prevents shock and post-partum hemorrhage, and makes anesthesia less in quantity. I have used forceps only three times in my last fifty cases; in my previous fifty cases I used them twelve times. I cannot agree with those who say we must not give it to primiparas; my best results have been with them. I have never seen a child born dead when this agent was used.

DISCUSSION

Dr. Leslie B. Wiggs, Richmond: There are two active principles in the posterior lobe, one a uterine-contracting and the other a blood-pressure raising agent. I think it will inaugurate contractions.

Dr. Greer Baughman, Richmond: I have had three failures; two of these were occiput posterior cases. I use fractional doses, half a decigram, and in half hour another half. I believe it is a substitute for forceps. The os must be completely dilated. It is a dangerous remedy when used wrongly. Passage and passenger should fit.

Dr. J. F. Winn, Richmond: It is a dangerous remedy. I recall a case of rupture of the uterus from this agent, followed by immediate death. We should diagnose accurately the cause of delay before using it. Do not blame a good thing if you do not know how to use it. I have not used it as much as Dr. Harrison has. If there is definite indication for the use of forceps, and you know how to use it, why not use the forceps? Do not take chances.

Dr. W. E. Anderson, Farmville: I class pituitary extract with the knife. It is more important to know when to use it than how. It does not take the place of forceps. You may have better results with forceps than with pituitary extract.

Dr. Virginius Harrison, Richmond: Ergot and pituitary extract are not the same in action and they may be combined in certain cases. There are eight preparations on the market, and we may be using the strong when we think we are using the weak.

Sarcoma of Both Ovaries in a Child of Three Years

Dr. F. H. Smith and Dr. J. C. Motley, Abingdon: A white girl, aged 3 years, giving a history of nausea and vomiting, had a mass in the abdomen, thought to be due to worms. There was great distention unless the bowels acted thoroughly. No fever was noted at any time. In the right iliac fossa was a mass that might have been the appendix. She had a history of having been butted in the abdomen by a goat. Later a mass was found in each iliac region, hard and doughy, not tender. Rectal examination disclosed that there was no connection between the two. Operation was done to relieve what was thought to be intestinal obstruction. Both tumors were removed and found to be sarcoma of the ovary. Five months later the child had an abdominal tumor, in fact several tumors. Death ensued within sixty days.

Caring for Premature Infants

Dr. S. G. T. Grinnan, Richmond: Aeration by osmosis should be tried when ordinary means to revive do not avail. The less the weight the more rapid is the loss of heat. Acid blood is found in premature infants. The electric pad gives uniform heat. Pure air is necessary for the lungs. Temperature must be kept at 90 degrees. Fatty soap is the best. Do not try to cleanse the mouth. Whey may be used when breast milk cannot be had. Evaporated, not condensed, milk may be used.

DISCUSSION

Dr. W. L. Harris, Norfolk: A home-made incubator is what has served me best, a rather deep padded box, with a hot-water bag. These children should not be shocked, and I think they are often killed by bathing. Start the nourishment early. Get milk from another woman if the mother cannot furnish it. Feed the baby according to what it can take. You may have to feed it with a medicine dropper, and ten or twelve times in the twenty-four hours.

Necessity for Study of Fetal Heart Sounds in Placenta Praevia

Dr. Greer Baughman, Richmond: Inability to hear the sounds is generally due to listening at the wrong place or to a dead fetus. The two portions of the fetus transmitting the sounds best are the chest in front or behind over the region of the heart. The fetus gasps because of peeling off of the placenta. The same thing may happen if the cord be compressed intra uterum. Then the fetus breathes in amniotic fluid. The sounds are hard to hear during uterine contractions.

DISCUSSION

Dr. A. T. King, Washington, D. C.: I have looked over the United States census statistics and I find 1,200,000 home obstetric cases to 100,000 hospital cases. This by the way of emphasizing the importance of home obstetrics. Why not give salines under the skin of the child? It is suffering from hemorrhage as well as asphyxia.

Chronic Catarrhal Otitis Media

Dr. C. R. Dufour, Washington, D. C.: Many suicides occur because of terrible noises in the head, beginning insidiously, with a sense of stuffiness. The patient thinks it is due to car-wax. The noises are worse at night, and affect one ear or both. The disease is progressive and rarely clears up of itself. It does not yield readily to treatment. Six months is not too long to treat. Iodin and oils vaporized in the middle ear are good.

DISCUSSION

Dr. George J. Tompkins, Lynchburg: The general practitioner is apt to overlook adenoids. I recall a case in which I found adenoids in which the family physician was satisfied there were none. I was convinced that they caused the trouble.

Dr. W. E. Driver, Norfolk: Deafness due to local conditions in the throat is too simple to talk about. Diseased tonsils and adenoids should be removed. The common idea that you can take your finger and scratch out adenoids is barbarous. The eustachian tube is sometimes permanently stopped by cicatricial contraction.

1. Ultimate Results in Cases of Cholelithiasis.—From a review of 160 cases Clark concludes that simple drainage is all that is necessary in cases of cholelithiasis in which there are no symptoms attributable to the presence of the stones. When the gall-bladder is thickened or greatly dilated, or if it is the seat of the so-called "strawberry change," as described by Moynihan, cholecystectomy should be the operation of choice. Of fifty-five gall-stone operations not associated with other gynecologic or abdominal conditions, 90 per cent. of results were traced. No patient returned for a second operation, and none had been operated on elsewhere. Of this number 69.5 per cent. were cured, 15.2 per cent. were greatly improved, and 2.1 per cent. were not improved. Of the entire number, 8.6 per cent. died after leaving the hospital from extraneous conditions not connected with the surgical operation.

Of seventy-seven cases of cholelithiasis with symptoms associated with other abdominal or gynecologic lesions 78 per cent. were traced; 59.7 per cent. were cured, 17.5 per cent. were greatly improved, 1.7 per cent. were slightly improved and 8.7 per cent. were unimproved. Since leaving the hospital, 3.5 per cent. died of intercurrent diseases not connected with the biliary operation. Of thirty-one cases of cholelithiasis without assignable symptoms associated with other abdominal or gynecologic conditions 86 per cent. of the patients were traced, 64 per cent. were cured, 16 per cent. were greatly improved, 4 per cent. were slightly improved and 8 per cent. (2 cases—both excessively neurotic) were worse than they had been before operation. It is specially noteworthy that in the second class of cases, in which there were unquestionable symptoms of diseases of the upper abdominal organs, in 13 there were visible changes in the appendices, ranging from mild to acute inflammations. Thus the error in diagnosis falls chiefly between appendicitis and cholecystitis. In several of these cases the condition of the appendix gave rise to the acute symptoms which had precipitated the operation.

From this analysis Clark learned that the worst results occur among the combined cases in which there are manifest symptoms due to biliary changes. The ratio of the cures is in direct proportion to the severity of the symptoms. The weight of evidence most emphatically favors the early removal of gall-stones. The mortality will be small, the proportion of cures large and the hazard of a return of the patient to the hospital for a second operation slight. In the light of the results secured in this large series of cases Clark believes that his stand of a decade ago, which favors the removal of gall-stones associated with other gynecologic or abdominal lesions, whether they are producing symptoms or not, is amply sustained.

2. **Cancer of Stomach.**—The 1,000 cases of cancer analyzed by Friedenwald occurred in 10,416 patients affected with various gastric disturbances (9.6 per cent.); the maximum liability to the disease lies between the fortieth and sixtieth year (65 per cent.); the greater proportion of cases occur in males; 588 males to 412 females. An hereditary history of cancer appearing in various portions of the body occurred in 104 of the 1,000 cases (9.4 per cent.). A definite history of trauma was elicited in 19 cases, in 6 of which there had been blows on the abdomen. In 229 cases in which hemoglobin estimations had been recorded, anemia was present in 189 (82 per cent.). The average of the hemoglobin estimations was 43. Chronic endocarditis was present in 114 cases (11.4 per cent.); arteriosclerosis in 696 (69.6 per cent.) of all cases. Of the 132 cases in which blood-pressure examinations were recorded, 121 (91 per cent.) present readings of 170 mm. or more. Albumin was present in 401 (55.9 per cent.), and albumin and casts in 334 (46.4 per cent.).

In the 1,000 cases of cancer there was a history of some previous digestive trouble in 232 cases (23.2 per cent.). Seventy-three cases gave a definite history of former gastric ulcer. A history of former indiscretions in diet was obtained in 321 instances (32.1 per cent.); a history of alcoholism was obtained in 152 instances (15.2 per cent.). A history of syphilis was obtained in 79 instances; tuberculosis of the lungs was present in 48 instances. Over 89 per cent. of the cases presented an entire absence of free hydrochloric acid. Lactic acid was present in 601 instances, or 81.9 per cent. of the 733 cases in which the gastric secretion was examined. The Oppler-Boas bacillus was observed in 582 cases, or 79.3 per cent., of the 733 cases. It was found only in those instances in which lactic acid was observed. Sarcina were observed in 24 instances (32 per cent.). Visible blood was observed in the gastric contents in 129 instances (7.5 per cent.). Coffee-ground contents was obtained in 653 instances (61.8 per cent.). Roentgen-ray examinations were made in 32 instances, 8 cases presenting cancer at the cardiac region and 24 at the pyloric region. Anorexia and vomiting are most prominent symptoms, being present in 89 per cent. of cases. Hematemesis is present in 25 per cent. of all cases and melena in 19 per cent. Occult blood appears in the stools in 92.5 per cent. The tumor was sufficiently advanced to be palpable in 72 per cent. of cases, but only in 30 per cent. of these cases within a half year of the first appearance of symptoms, while in 60 per cent. of cases this symptom was manifested after the first six months. Clinically in 60 per cent. of cases the cancer is located at the pyloric area, in 7 per cent. at the cardiac area, and in 30 per cent. there is a general involvement.

Operations were performed in 266 instances (26.6 per cent.). Of these 138 (51.8 per cent.) were exploratory operations. Gastro-enterostomies were performed in 98 (36.9 per cent.); gastrostomies in 25 (7.8 per cent.), and pylorectomies and gastrectomies in 9 (3.3 per cent.). Of these there is not one patient living. It is therefore evident that the early diagnosis of cancer of the stomach is still fraught with difficulty, and that until more certain methods are available exploratory incisions should be urged on all persons over 40 years of age having gastric symptoms which are not relieved after a few weeks' treatment, especially is this the case if there be some loss of flesh, an absence of free hydrochloric acid in the gastric contents, and occult blood in the stools. Inasmuch as in a certain proportion of cases gastric ulcers become cancerous, it is well in all operations for gastric ulcers to consider the advisability of performing excision or partial gastrectomy to prevent possibility of the transition of ulcer into cancer.

4. **Laboratory Diagnosis in Congenital Syphilis.**—According to Grulee there is no test which is proved to be pathognomonic of congenital syphilis in the early stages between the birth and the development of active symptoms. The Lange gold chlorid reaction on the cerebrospinal fluid offers at present some hope that the evidence obtained in this way may be of distinct benefit. The Noguchi luetin test has a distinctly negative value, inasmuch as in all cases not syphilitic the reaction was negative.

9. **Examination of Urine for Tubercle Bacilli.**—The important point brought out by Churchman is the fact that in vesical tuberculosis, if the ulcer is on the vault of the bladder, in which it is seldom or never reached by the small amounts of urine present there at any one time, tubercle bacilli may quite readily be absent from the urine, or at least not present in great number. In such cases, therefore, and indeed in all cases of vesical tuberculosis one should add to the catheterized urine to be examined for the organisms, washings from the bladder surface. In obtaining these washings it is advisable to allow fluid to flow in until the bladder is distinctly distended, so as to obtain material from its whole surface.

10. **Albumin in Sputum in Tuberculosis.**—Cocke has collected from the literature the results of the analyses of 3,951 cases in all stages (not including 20 of his own), in which there was a positive albumin reaction in the sputum in 3,778, or 95.6 per cent. These cases were all definitely known at the time or later proved to be tuberculosis, so that the conclusion is inevitable that the large majority of all cases of tuberculosis show a *positive* albumin reaction in the sputum.

17 Roentgen Ray as Diagnostic Help to Pediatrist. L. E. La Fétra, New York.
18 Three Cases of Diabetes Mellitus in One Family. C. G. Moore, Schuyler, Neb.

12. **Manifestations of Influenza in Young Children.**—One thousand six hundred and fifty sputum cultures made from 1,053 patients during the winter and spring seasons of the past five years period showed that the influenza bacillus was present in from 32.5 to 42 per cent. of the cases. Holt believes that this accounts for many obscure symptoms seen in these patients. On two successive days in April sputum cultures were made from all the hospital inmates—doctors, nurses and patients. Of 90 persons examined, 31 showed the presence of influenza and 3 others had shown it previously, making a total of 34 infected persons, or 38 per cent.

The most marked prevalence of influenza was in the wards in which the patients with bronchitis and pneumonia were received. In two such wards, containing 21 patients, 10 had influenza. Of 8 nurses in attendance in these wards, 5 showed influenza. Six of the patients were suffering from bronchopneumonia, 3 others previously had slight temperatures not explained by the other symptoms present; a fourth patient, one of tuberculous meningitis showed only a few influenza organisms. Two nurses had no symptoms suggesting influenza infection, but one shortly after the culture was taken developed a severe cold; the other three were suffering from catarrhal symptoms of various degrees of severity.

A nurse in charge of a special ward containing 3 children who were suffering from influenza, showed the organism in the sputum. She had previously suffered from a mild cold. Of the remaining 25 nurses in the hospital only 4 showed the *B. influenza*, and 3 of these had suffered from colds or a nasopharyngeal infection. The resident physician had a severe paroxysmal cough and his sputum showed great numbers of influenza bacilli. Of 10 cases of pneumonia in the hospital at the time of the routine examination the sputum of 8 showed the *B. Influenza*. Of 8 children admitted with pneumonia during the week following, 5 gave positive influenza cultures. Since the number of children admitted with influenza is so large the presumption is that the nurses contracted it from these children and then possibly spread the infection to others.

An unusual prevalence of influenza has been noted in some other institutions in the city in which careful sputum cultures have been made. Dr. Swift of the Rockefeller Institute Hospital informed Holt that of 13 pneumonia patients during the first three weeks of April, 8 showed the presence of the *B. influenza* in the sputum cultures. Holt regards the want of correspondence between the general symptoms and the temperature as quite diagnostic. He knows of no disease in which such high temperatures are seen with so few general symptoms as in influenza.

13. **Causes and Treatment of Eczema in Infancy.**—Freeman believes that the eczema of infancy and early childhood, which is occasionally due to external irritation, is usually due to gastro-enteric derangement and must be attacked primarily by correcting that derangement. The food should be cut down to caloric requirements, the ration should be balanced and digestion aided. Stewed fruits and cream should be prohibited. The parts affected should be kept well covered with non-irritating applications.

19 *Cancer of Uterus. Possibilities of Cure by Radical Abdominal Operation. F. Cobb, Boston.
20 *Cancer of Rectum. D. F. Jones, Boston.
21 *Cancer of Bladder. A. L. Chute, Boston.
22 Cancer of Prostate. H. Binney, Boston.

19. **Cancer of Uterus.**—In a series of 49 simple abdominal hysterectomies done by numerous men and referred to by Cobb there was an immediate mortality of over 34 per cent. and only 19 per cent. of cures. He concludes from these figures that an abdominal hysterectomy which makes no attempt to dissect the ureters and remove the parametrium, to say nothing of the pelvic glands, cannot be advocated as a safe or reasonable operation for cancer of the cervix because it exposes the patient to increased danger from shock, hemorrhage and peritonitis without making any wider removal of the disease and its lymphatics than in the simple vaginal hysterectomy. There were 40 radical Wertheim hysterectomies including 23 of Cobb's personal cases, with an immediate mortality of 22 per cent. and 50 per cent. of cures. In addition there were 27 abdominal hysterectomies for cancer of the fundus, 7 of which were Cobb's personal cases. The immediate mortality was 4, or 14.8 per cent., and of those cases in which the operation was done over five years before, only 42.8 per cent. were cured.

Summing up, Cobb says, that the extended radical abdominal operation is the method of choice, the method that offers the greatest possibility of cure in cancer of the cervix if done by specially trained men. The earlier the diagnosis is made the greater the chance of cure. Simple vaginal hysterectomy is a safer and better method than simple abdominal hysterectomy in ordinary hands. The extended abdominal operation is contra-indicated in marked adiposity and in feeble patients. Cobb has done the Wertheim operation for cancer of the cervix 34 times with an immediate mortality of 5, or 14.3 per cent. In addition he has done abdominal hysterectomy for cancer of the fundus 7 times with no immediate mortality. Only 6 of the cancer of the cervix cases were done over five years ago, 5 of these patients are alive and well and free from recurrence from five to thirteen years. The cause of death in Cobb's cancer of the cervix operations is as follows: One patient died of peritonitis within forty-eight hours; one in twelve hours of shock; one on the tenth day, cause of death not made out at necropsy; one in the fifth week of iliac thrombophlebitis, and one in the tenth week of intestinal obstruction.

20. **Cancer of Rectum.**—The results obtained in carcinoma of the rectum Jones states depend almost entirely on the character of the growth and its duration, and comparatively little on the operation done. That is, they depend on the vigilance of the patient, and the vigilance and thoroughness of the physician and surgeon. Certain cases in which there is much tenesmus demand a radical operation, even when hopeless, simply for the relief it gives, and which is not obtained in many cases with a simple colostomy. Theoretically, the combined abdominosacral operation is the operation of choice. Practically the mortality is too high except in selected cases. Statistics of late results are not sufficiently good to warrant taking the extra risk in the obese, the feeble, and in men over 50. The combined two-stage operation, if the second stage is done under spinal anesthesia, will give a mortality between 15 and 20 per cent. A serious objection to this operation is the danger of infecting the denuded area with cancer cells brought through the lymphatics from the growth. The Kraske operation is the operation of choice in the obese, the feeble and patients over 60.

21. **Cancer of Bladder.**—Chute believes that so long as a growth is confined to the mucous layer of the bladder there is probably no lymphatic involvement; that the moment it invades the deeper layers we have lymphatic involvement; that when this has taken place the lymphatics of the pelvis must be removed, no matter how small the original focus is, if patients are to be cured. Chute feels that we must accept total cystectomy temporarily at least, as a necessary part of any attempt at radical treatment of malignant disease near the bladder outlet.

40 *Subcutaneous Injection of Oxygen. H. O. Howitt, Guelph.

40. **Subcutaneous Injection of Oxygen.**—Howitt's experience with the intramammary injection of oxygen according to Derose which now covers nearly two years, includes the dyspnea of tuberculosis, gas poisoning, pneumonia (lobar and lobular) edema of the lungs, bronchial asthma and operative cases. In no case were any ill effects noticeable, either at the time or afterward. One asthmatic said that it relieved him, but Howitt did not notice appreciable improvement. The oxygen is generated from sodium peroxid coming in contact with water in a closed cylinder, and the gas set free escapes by means of a long rubber tube, at the distal end of which is an aspirating needle which is inserted into the subcutaneous tissue. The tube is then oiled and by a pumping action of the hand, sufficient force is used to raise a lump once or twice as large as the closed fist. The oxygen injected by this method forms a local emphysema which lasts for hours and may travel over the surface of the body. Apparently the body only absorbs that which is necessary. It is really the formation of an artificial lung.

49 *Clinical, Pathologic and Experimental Study of Lesions Produced by Bite of "Black Fly." J. H. Stokes, Ann Arbor, Mich.
50 *External Vaccine Therapy. H. P. Towle, Boston.
51 Autoserotherapy of Certain Diseases of Skin. J. S. Hilario, Manila.
52 Herpes Zoster Following Arsenic. R. C. Finlay, Grace, Miss.

49. **Study of Black Fly Bite.**—To the question as to whether the bites of the black fly are capable of giving rise to constitutional reaction in man, Stokes answers that the temperature in a small child which received twenty-five or more bites in one afternoon, never went above normal, although the lymphadenitis was marked and the child fretful and restless. Several persons under his observation expressed themselves as having felt "tired and stiff all over" after being severely bitten by the flies early in the season. Nothing comparable to the severe reactions described in the literature has come under Stokes' observation.

50. **External Vaccine Therapy.**—Vaccines were used externally by Towle in more than 150 cases. The vaccine containing preparations manifested their therapeutic activity as abundantly and so consistently that long continued experimentation was unnecessary to convince him that it was practicable to obtain vaccine effects by external methods of administration. Of the ordinary fatty substances, the final selection as ointment bases, alone or in combination was, in the order of preference; lanolin, vaselin, cold cream and (for use on the hairy parts) a fat emulsion known as liquid cold cream. Occasionally, one or the other was used alone, but increasing experience gradually led to the more frequent use of combinations.

No fixed formula has been followed. Instead, both composition and proportion have been varied, as the varying conditions in each case seemed to indicate. In a general way, the simplest formula, plus more or less powder, seemed the most useful in the presence of exudative conditions. The composition of the base was varied in accord with the ordinary rules for the use of pastes and ointments. For pastes, starch was ordinarily the substance added to stiffen the base. For ointments, the greatest satisfaction was derived from varying combinations of glycerin, vaselin, distilled water and lanolin, and of olive oil or almond oil, lime-water and vaselin. On the hairy parts, the use of pastes and ointments is inconvenient and frequently undesirable. As a compromise between the frequent use of a greasy but more or less penetrating salve and the more easily applied but superficially acting lotion, a thin emulsion, with cold cream added to give it more body, has been found to be an efficient means of applying vaccines to the scalp and other hairy parts.

Regardless of the form of the base chosen, it was found desirable that the vaccine preparation should be rubbed in with fingers until a considerable portion has disappeared, except in the case of an exudative eruption, in which the broken surface of the skin facilitates absorption. In the latter, it suffices merely to smear the vaccine preparation over the surface. External vaccine therapy was found the most efficient in the treatment of acute inflammation of infections whose seat is superficial, and therefore easily reached from without. Of all infectious processes, the staphylococcic is the most easily influenced by external vaccine therapy. On other infections the effects of external vaccine treatment are less marked, and in the various forms vary considerably.

Journal of Nervous and Mental Disease, Lancaster, Pa.

November, XLI, No. 11, pp. 681-744

53 *New (Familial) Form of Progressive Spinal Myopathy. C. L. Dana, New York.
54 *Spinal Fluid Cell Counts in Untreated Cases of Cerebrospinal Syphilis. H. W. Mitchell, I. A. Darling and P. B. Newcomb, Warren.
55 Psychoses Among Negroes. E. M. Green, Milledgeville, Ga.
56 Cerebellar Syndrome of Babinski. Report of Case. H. K. Marks, New York.

53. **New Form of Spinal Myopathy.**—Dana cites a case occurring at the age of 53, in a family in which ten cases were known to have developed in three generations. The clinical history shows that its course is like that of a disease which destroys one group of spinal motor cells one after another. It is not a slowly developing atrophy followed by paralysis, but a rather sudden paralysis followed by atrophy. The disease progresses and the patient dies in a period of about one year. The patient's maternal grandmother had the same disease and died of it in her forty-first year. Maternal grandfather healthy. There were three children borne by her mother. One died at birth and one, a sister of the patient, died at 47 of gastric ulcer. Her mother died of this progressive paralysis at the age of 47. In her case the disease began in the fingers and then went to the legs and throat and the whole trouble lasted a year. The mother had three sisters who died of the same trouble, one at the age of 52, one at 42 and one at 37. In two of these cases the trouble began in the arms and in one case in the legs. In all cases the disease progressed upward. The mother had a brother whose son developed the trouble at the age of 35. She had two other sisters who did not have the disease, each married and had healthy children. Four are known to be living at ages of 50 to 60. In addition to this, three sons of the grandmother's sister died of the family disease.

54. **Spinal Fluid Cell Counts in Syphilis.**—In a review of thirty-four cases a count of three or less was found at some time in all but two, both far advanced paretics. Seven of the cases showing high average counts were paretics exhibiting excitable, grandiose tendencies during the period they were under observation, but similar results were also found in cases showing pronounced dementia and comparative remission of active symptoms. High counts were found in all stages of the disease, from the first to the tenth year of well defined paretic symptoms. In several cases very great variation was shown in the counts at two weeks' intervals without any appreciable changes in the patients' symptoms. Low average counts were also found to occur in all stages

of the disease. Of ten patients with the highest count below twenty, seven are dead or bedridden, two show remission of active symptoms and one is ambulant but much demented. The period of the disease in these cases varied from the first to the thirteenth year.

The authors conclude that great variation in the cell count may be found at short intervals in any stage of the disease. Both high and low average counts persist for months at a time in various stages of the disease. A low or falling count is common but not universal before death. A reduction in the cell count to the normal limit frequently occurs in progressive, untreated cases at any time during the course of the disease. The reduced cell count, accompanied with persistence of a positive Wassermann in the fluid, cannot be regarded as having valuable prognostic significance.

67. Toxic Diseases of Nervous System.—Four cases are cited by Fisher. The first was a case of ascending paralysis, with attending neuritis, which followed the usual course of extension, later involving the upper extremities and the bulbar nerves, resulting in respiratory failure. The pathologic findings are definite, involving both the peripheral and central nervous system. The course of the disease was longer than that usually described, extending over six weeks, but otherwise the case was typical in its manifestations. The second case was one of a distinct infection of an unknown character, involving the meninges, as shown conclusively by the rigidity of the neck, and the increased cell count in the spinal fluid. The neuritis of the lower extremities, a loss of reflexes, and ascending paralysis suggest a condition of the nature of Landry's paralysis. A third case from the symptoms suggested either some infection involving the membranes at the base of the brain, or basal syphilitic meningitis. The necropsy showed, however, a sarcomatous basilar meningitis. Small bodies resembling tubercles were found scattered over the meninges and the base of the brain, and two small tumors were found in the frontal lobes, incapable of causing any symptoms. There was also a secondary involvement of the liver and spleen. The fourth case did not correspond to syphilis of the nervous system nor did it respond to antisyphilitic treatment. There was evidently an acute affection of the nervous system, cord and bulb, suggesting acute ascending paralysis or poliomyelitis. Fisher suggests that possibly we may in the future put many of these cases of myelitis or primary lateral sclerosis down to toxic agents, especially when, as in one of these cases, there was no evidence of syphilis.

100. Pyorrhea Alveolaris or Rigg's Disease.—In August, 1914, Bass and Johns found amebas in a stained preparation of pus from a case of pyorrhea alveolaris. They examined specimens from six other cases. Apparently the same species of ameba was found in each of the seven cases. Their close resemblance to the entameba of amebic dysentery and the marked specific favorable influence of treatment with ipecac and emetin in amebic dysentery led them to expect that the same effect might be exerted on this form of amebic disease also. They began treating patients with emetin hypodermatically. They examined material from the lesions in eighty-seven cases of pyorrhea and found ameba in eighty-five of them. One of the negative cases was a single slide prepared a distance from the laboratory, from the gum of a patient who was convalescing from plague. Pus could be squeezed from her gums and the diagnosis of pyorrhea alveolaris seemed indicated. The other negative case was that of a 13-year-old girl with acute gingivitis, involving all the gums, of about eight days' duration. Thorough search failed to show ameba, and the authors now believe this probably was not a case of pyorrhea alveolaris or Rigg's disease.

They also made more than 100 examinations of preparations made from apparently normal gums and teeth, either in the mouths of patients who had the disease involving other teeth, or in people who appeared to have normal gum margins. They have not been able to find amebas in a single instance. They have, however, found them on several occasions in instances in which the gum margin appeared inflamed and diseased. In several instances they found amebas in similarly mildly inflamed and "easy to bleed" gum margins of one or more teeth in patients who had well-advanced Rigg's disease around other teeth. They found amebas around teeth in what they considered to be all the different stages of the disease in the same case, from the slight redness at the gum margin and tendency to bleed easily to the tooth hanging loose in its socket or standing, entirely stripped of gum on the exposed carious bone.

The doses of emetin experimented with have been from ½ to 1 grain. Only one dose was given in a day. Several cases have been given a dose daily for several days. Others were given one or more doses until the amebas disappeared. In several instances no amebas could be found the next day after the first dose was given. In a few, however, they were found the next day after emetin had been given on two successive days. In no case have the authors been able to find amebas the next day after emetin had been given on three successive days. In one instance they found amebas on the fourth day after the last emetin had been given; in another instance on the sixth day; in several instances none could be found after seven days or longer intermission of treatment.

102. **Artificial Cultivation of Rabies Virus.**—Proescher describes his method as follows: Thirty c.c. of sterile, not filtered, sheep serum is filled into large test tubes 2.5 by 15 cm. and incubated for forty-eight hours, to prove the sterility of the serum. A large piece of the brain substance of a rabid animal removed under aseptic precautions is placed in the bottom of each serum tube, the serum sealed with paraffin oil, and the tube closed with a cotton plunger. The tubes can be kept under aerobic conditions. Proescher says that it is advisable to inoculate at least fifty tubes, as few only will show a growth. Typical changes in the culture medium are not noted. Tubes showing gas formation or coagulation of the serum are rejected. The tubes should be kept at least two months under observation and examined every eight or ten days. The first primary culture Proescher obtained was incubated for two months; repeated examinations before did not show any growths. For subcultures, serum bouillon only (one to ten) is used, as in the common culture medium no growths can be obtained. The serum bouillon after twenty-four hours' incubation is homogenous, cloudy, and after several days' incubation shows a granular sediment. The micro-organisms of the primary culture appear after staining with methylenazur in the form of cocci and oval bacilli, varying in size from just visible to 0.2 to 0.3 micron; in the form of diplococci or aggregated in small groups or short chains. With the Gram stain, using carbolfuchsin as counterstain, the larger forms are more or less Gram-positive, while the smaller forms are faintly stained red. The micro-organisms appear after several transplantations in serum bouillon somewhat larger, and the majority of the micro-organisms are Gram-positive. The inoculation of these cultures into rabbits, rats, and a monkey produced typical rabies.

104. **Operative Treatment of Contracted and Deformed Hands.**—The deformities are reduced by Elliott by forcible reduction and open operation combined. Most of the displacements can be corrected by redressing alone. The reduction is made under profound ether or chloroform narcosis. The fingers are taken singly, forcibly breaking down the contracture or hyperextension and redislocation if such exists. If the finger is contracted, it is forcibly hyperextended. The reverse is done in case of hyperextension deformity. All the hand deformities are overcorrected. The hands are placed on splints padded in such a manner as to keep up a continual overcorrection of the deformity. For three or four days the pain is intense and has to be partially controlled by sedatives. Each joint is wrapped in gauze, saturated with a lotion composed of aconite, belladonna, and glycerin. This dressing is extended over the back of the hand considerably above the wrist, and is covered with oiled silk. A very firm bandage is applied, leaving the tips of the fingers exposed. The pressure must be firm enough to prevent much swelling. The gauze is kept wet with the lotion and over this an ice bag is applied. The tips of the fingers offer a control, and undue localized pressure is readily detected. The splint is used for two weeks. The wet dressing is discontinued as soon as the reaction symptoms subside usually in four or five days. When the pain ceases, it does not return. Not infrequently certain deformities will not give way without a cutting operation. Whenever this is necessary, cutting should be done first. After the wounds are healed, redressment can be carried out.

3. **Treatment of Snake-Bite.**—The value of local remedies in snake-bite treatment, according to Acton and Knowles is strictly limited by two factors, the necessity of inoculating the patient with them before a fatal dose of venom has been absorbed, and the fact that only such venom as they happen to come into contact with *in situ* will be destroyed. They must be given before one minimum lethal dose has been absorbed into the circulation. For man, for 10 minimum lethal doses of cobra venom, this period is about ten minutes. The more concentrated and the larger the dose of venom given the shorter is the period available. An efficient ligature increases this time limit. Subcutaneous injection of these remedies in solution gives much better results than does incision and the rubbing in of moistened crystals. If they be given subcutaneously, no incision should be made.

The authors' experiments show that the immediate injection of 10 to 20 c.c. of a 1 to 5 per cent. solution of gold chlorid is the most efficient local remedy. In some cases this measure alone may save life. In others it will reduce to a minimum the amount of venom which has to be dealt with by means of systemic remedies. When brought into contact with large doses of venom in concentrated solution these remedies exert a more intense action than when acting on small doses in dilute solution. In the case of bites on fingers or toes, in which large volumes of fluid cannot be given hypodermically, two lines of procedure are open. Either a complete dissection of the area of the bite should be made and crystals of potassium or preferably of zinc permanganate should be rubbed in. Or an injection of ½ to 1 c.c. of a concentrated solution preferably of gold chlorid, should be made into several sites in the neighborhood of the punctures. Acton and Knowles are inclined to think that the latter method is the better.

The use of ox bile as a solvent improves the action of weak solutions of gold chlorid and iodin trichlorid. A 5 per cent. solution of gold chlorid in ox bile is not of greater value than a corresponding solution in saline. Bile improves the action of strong solution of permanganates but not of weak solutions. On intravenous injection these remedies are said to be not merely useless, but, owing to the danger of their causing intravascular clotting and pulmonary embolism, they are dangerous.

4. **Treatment of Snake-Bite with Potassium Permanganate.**—Bannerman concludes that a dog bitten by a cobra cannot be saved by the local application of powdered potassium permanganate rubbed in after free incision of the bitten place; nor by a similar application of a solution of the powder. It may be saved, however, by the immediate subcutaneous injection of 10 c.c. of a 5 per cent. solution of potassium permanganate; but this solution is so strong that gangrene of all the tissues of the foot is produced. If this treatment be delayed for even two minutes, a fatal result cannot be averted. A dog bitten under natural conditions by a Russell's viper, cannot be saved by the local application of potassium permanganate.

5. **Experimentally Produced Goiter.**—The pathologic process which results in the formation of goiter in rats, McCarrison says, is essentially of a diffuse character. This process initially affects epithelium of the gland giving rise to hypertrophy, hyperplasia and the formation of many new acini, and may ultimately lead to degeneration and death of the parenchyma cells. It is an exaggeration of the normal physiologic process and results primarily in an increased production and an increased absorption of colloid which may be followed by cell-exhaustion as a consequence of overwork and malnutrition. The transition from the physiologic to the pathologic state is very gradual and the line of demarcation between the two is arbitrary. The pathologic changes which result in the development of goiter in rats are the same as in man, and are probably, therefore, due to the same goiterigenous agent or agents. The goiterigenous agent or agents are of the nature of toxins which stimulate the thyroid gland to abnormal activity. The toxic agent or agents of endemic goiter are produced in the intestinal tract of man and animals. The goiterigenous agent or agents are intermittent in their action in the case of endemic goiter—continuous in their action in the case of Graves' disease. There is no evidence that the blood or thyroid glands of goiterous individuals contain organisms of a bacterial or protozoal nature.

6. **Etiology of Endemic Goiter.**—McCarrison claims that at certain seasons of the year goiterigenous substances may be present in the feces of goiterous and non-goiterous persons and animals which are capable of causing the development of massive goiters in rats. Factors of nutrition are not of paramount importance in the genesis of goiter in rats. Insect transmitters of disease are not responsible for the spread of goiter in rats. House, room, cage or fish-tank infection is an important factor in the genesis of goiter. The excreta of the human or animal subject is the main source of the disease. The infecting agent is capable of life, and it may be of some degree of growth, outside the body of man in fecally contaminated soil or grossly polluted water. Suspicion points to intestinal anaerobes as possessing a goiterigenous influence on the thyroid gland. Water, food, soil or other mediums whereby the infecting agent or agents of the disease reach the bodies of man and animals are of importance only as vehicles of its transmission.

12. **Experimental Beriberi.**—Of twelve pigeons fed by McCarrison only on dry polished rice, seven developed typical polyneuritis gallinarum within ten to twenty days. The remaining four escaped the disease within the period of the experiment. Of twelve pigeons fed only on boiled polished rice, nine developed typical polyneuritis within ten to twenty days. The remaining three escaped the disease within the period of the experiment. Of twelve pigeons fed on liberal diet none developed any signs of disease. Blood agar on ordinary agar plates were smeared with portions of the internal organs of six pigeons suffering from experimental beriberi produced as a result of the consumption of polished rice; innumerable colonies of a bacillus resembling that of hog-cholera appeared on the plates, after twelve to fifteen hours' incubation at 37 C. in all six cases.

The organs of three out of four control pigeons examined were sterile, while a very few colonies of this bacillus were obtained from the internal organs of the fourth. A few colonies of this organism were obtained from the organs of four out of eight pigeons which were fed on polished rice, but which showed no clinical signs of the disease within the period of the experiment. Living cultures of this bacillus, when inoculated into liberally fed rabbits, fowls and pigeons (a total of twenty-eight animals) produced in nineteen, or 67.8 per cent., within a period of nine days, symptoms which were indistinguishable clinically from polyneuritis gallinarum. The sciatic nerves of all such cases showed degenerative changes of greater or lesser degrees of severity, while those of seventeen controls, whose organs were sterile, have shown no evidence of pathologic change.

17. **Histologically Non-Malignant Angioma.**—Shennan's case was one of angioma which displayed no sarcomatous transformation or other histologic indication of malignancy, yet gave rise to numerous secondary growths throughout the body. The patient was 23 years of age. The clinical sequence of events was as follows: A toxic gastro-intestinal attack about 1900, thirteen years ago, when the patient was about 10 years of age. The influenzal attack, with barking cough, suggesting mediastinal pressure, in December, 1907, six years ago, when the patient was about 17 years of age. Hemoptysis, June and July, 1908, five and a half years ago. No return of symptoms until in July, 1909, when also hemoptysis occurred; a year later it was most persistent. Enlargement of the spleen was first detected in October, 1909, some time before her first attack of splenitis. Hemorrhage into the pleural cavity at the time of the first attack of splenitis in November, 1909. At the same time dulness and crepitation were detected for the first time near the root of the left lung. Petechial hemorrhages with beginning formation of nevi in the skin were noticed first about August, 1910. Vomiting of blood occurred on two occasions about October, 1911. Diarrhea with ascites developed in the late autumn of 1912; at same time enlargement of liver. About the same time swelling was detected in the sternum. March 3, 1913, ascitic fluid drawn off was seen to consist largely of blood. May, 1913, the ovaries were felt to be enlarged and cystic. Thrombosis of mesenteric vessels occurred four or five days before death, with infarct of part of intestine. The clinical history pointed to the mediastinum as the earliest seat of the disease. The end came suddenly and seemed to be due to heart failure. Metastases were found in the lung, spleen, liver, ovaries, sternum, left clavicle and lumbar vertebrae. A detailed postmortem report is presented.

21. **Nuclein, Nucleic Acid and Antibody.**—Bedson found that nuclein alone, out of the three leukocytosis-producing substances examined, brings about a rise in the opsonic index. This rise is first in evidence twenty to thirty minutes after the injection, is still marked seven and one-half hours after, but has completely disappeared in twenty-four hours. The increased opsonic activity of the serum is readily destroyed both by heating for thirty minutes at 56 C. and by diluting with normal saline. It would appear, therefore, that there is no increase in the thermostabile opsonin normally present in the serum. This effect is not produced by all preparations of nuclein or nucleic acid, as, out of the four examined, two were found to be without effect. Seeing that these two latter preparations were the purest of the four, it would appear probable that this effect is not due to the nucleic acid radicle but to the presence of some impurity.

26. **Boas-Oppler Bacillus.**—Specimens of the Boas-Oppler bacillus were obtained by Galt and Iles from three definite cases of carcinoma of the stomach; in these cases free hydrochloric acid was absent, and lactic acid was present in the stomach contents. Isolation and primary cultivation were affected on special mediums, and the morphologic and cultural characters were compared under standard conditions with those of a known strain of the *B. bulgaricus.* The evidence went to prove that the Boas-Oppler bacillus is identical with the *B. bulgaricus* and not an organism *sui generis.* True dichotomy was observed in cultures both of the Boas-Oppler and of the *B. bulgaricus,* indicating that another member of the long rod group of lactic acid bacteria, namely, the *B. bifidus* of Tissier, is probably identical with the above organisms. The inference was drawn that in cases of cancer of the stomach it is the absence of hydrochloric acid that allows of the growth of the bacillus, and that the lactic acid is formed as a result of the activity of this organism.

30. **Obligate Anaerobes in Alimentary Tract of Infants.**—Two types of strict anaerobes were found by Dalyell in the intestinal tract eight to twelve hours after birth, and in the first forty-eight hours of life were more abundant than the facultative anaerobes of the coliform type. The powerfully fermentative and proteolytic *B. aerogenes* was present within twelve to twenty-four hours after birth, in all cases examined. The other anaerobe, also constantly present, is acidophilic and a feeble fermenter of sugars is markedly pleomorphic, and is affected by symbiosis and by variations in culture media. At the end of the first week of life, facultative anaerobes of the coliform type were numerous, but the same two obligate anaerobes were still present in fairly large numbers and could be demonstrated by cultivation in special media.

47 General Principles for Military Surgery. (Blessures de guerre.) E. Delorme.

39. **Pillow Extension.**—Chaput gives an illustration of this means of treating compound fracture of the leg. He says that it not only is simplicity itself, but it acts better than more complicated apparatus and has several special advantages. The leg is dressed as usual with gauze and cotton applied thin and smooth all around the leg from the top of the foot to the knee. The leg is then placed lengthwise on an ordinary pillow, not too thick, the heel at the lower end. The sides of the pillow are then brought up and crossed over the leg and a bandage is wound tight around the whole to form a solid cylinder. A strip of cloth is pinned to the lower

part of the pillow on each side, and these are tied together 4 inches below the foot and a weight suspended from them.

41. **Wounds from French Firearms.**—Delorme reviews his experience in treating about 700 Germans wounded by the French arms, and comments on the remarkably large proportion of fractures of the legs, thighs and arms and the rarity of abdominal and chest wounds. He was also impressed by the lack of complications, except tetanus, which was comparatively frequent. The projectile had passed entirely through the foot in many instances, but there was no tetanus or gangrene or erysipelas in any of these cases.

42. **Chlorinated Lime in Treatment of Hospital Gangrene.**—Vincent found in the Madagascar campaign that the rotting wound was rapidly transformed to healthy conditions when it was dusted with fresh chlorinated lime mixed with about ten parts pulverized boric acid. He first cleanses the wound and then covers it generously with this antiseptic powder, dusting with it the skin around. In two or three days the wound assumes an entirely different aspect. He changes the dressings in twenty-four hours if there is much secretion; otherwise he waits for forty-eight. He adds that a 20 per cent. solution of iodin would certainly aid in warding off trouble if it could be applied at the time of the first-aid dressing. It might be possible to include the material in the first-aid packet so that the wounded could make the solution fresh as needed.

43. This article was summarized recently, p. 1684.

44. **Dysentery.**—Mathieu emphasizes that we should not speak of "dysentery" but of "dysenteries," as there are several kinds of dysenteric colitis. Even without waiting for bacteriologic examination it might be advisable to give an injection of antidysentery serum, as it is most effectual when administered at the first signs of dysentery of non-ameba origin. He has found useful a rectal injection morning and night for two days of silver nitrate, 0.25 gm. to a liter of tepid distilled water, suspending then or continuing according to indications. Among other remedies advocated he mentions sodium sulphate for its laxative and modifying action, 5 or 10 gm. in tepid water in the morning if there is not much solid matter in the stools. When there is actual diarrhea he gives smaller doses and gives a little opium with it. After subsidence of the dysentery, a course of small doses of the sodium sulphate may aid in restoring normal conditions in the colon. Persons with dysentery should be fed according to the principles applied in feeding infants with bowel trouble; nothing but water at first, or lactic-acid lemonade with 5 per thousand sugar, taking half a liter at first and then a liter. Sugar is useful in these cases, as it is nourishing and can be taken up to 50, 100 or 150 gm. a day. Fluid food can then be resumed, gradually coming to a vegetable diet with a little ham or roast chicken.

45. **Dentistry Protheses for the Wounded.**—Martinier and Roy remark: "The surgical prothesis as a branch of dentistry owes its origin to Claude Martin of Lyons, and it is thanks to him and to the French school that it has reached its present state of high perfection." Such protheses are useful not only to restore the shape of the jaw, but to promote the healing of a fracture of the jaw. This lesion is particularly serious on account of the wound being constantly bathed with saliva and exposed to infection of all kinds from the mouth. When suture is attempted at once there is almost inevitably suppuration, with additional and avoidable destruction of tissue. The ordinary measures for reduction of a fracture elsewhere cannot be applied to the jaw, but dentistry methods answer the purpose ideally if they can be applied early enough, immobilizing the fracture and permitting healing with the minimum of disfigurement and functional disturbance. "The collaboration of the dentist is thus indispensable to the army surgeon for early assistance in treating wounds, not only of the jaws, but of the skull, while his aid is of paramount importance in the later treatment of wounds leaving defects in the jaws, nose and ears." (The organized dentists of Paris have appointed a committee for assistance to aid in treating injuries of the jaws and face, and offer their services to the surgeons at the front.)

50 *Hypertrophic Stenosis of the Pylorus in Infants; Five Cases. L. Exchaquet.
51 Intermittent Hydrosalpinx. P. Wanner.

48. **Artificial Heliotherapy.**—Du Pan has tried various lights for treatment of bone and joint diseases, but discarded the arc light, as it generates too much heat. The quartz mercury lamp sends out rays most closely approximating direct sunlight, but the middle ultraviolet rays act on the skin and, although useful for lupus and other superficial lesions, they are not only useless but injurious in treating deep lesions. They can be filtered out by interposing a sheet of "pastel" glass, white on the cut edge, which sifts out these middle ultraviolet rays. With a lamp constructed on this principle, with air passing out through a chimney at the top, the skin exposed to its light never gets warmer than 40 C. (104 F.), and there is no perspiration to debilitate the patient and make him thirsty. The lamp has 7,000 candle power and is run with a 500-volt current obtained from the street railway system. Four or five children are exposed to the light at a time. They lie on a large table which slopes down toward the center. Each wears goggles to protect the eyes, but no clothes, the aim being to imitate as closely as possible with artificial light Rollier's method of exposure to the direct sunlight in the Swiss mountains. The results in the thirty-two cases thus treated have been extremely encouraging. They include tuberculous processes in the knee, spine, hip-joints, etc., osteomyelitis, and two cases of chronic peritonitis. One girl of 6 had been operated on two years before for an extremely painful tuberculous process in one knee. She later developed tuberculous keratitis and the other knee became swollen and painful. She was then given a course of the artificial heliotherapy and there was no further pain aften ten exposures. By the end of three months the knee was apparently normal and the child had gained 900 gm. in weight.

49. **Landau's Color Reaction in Diagnosis of Syphilis.**—This simple color reaction was described recently in The Journal, Oct. 10, 1914, p. 1317. The reagent is a 1 per cent. solution of iodin in tetrachlormethane (carbon tetrachlorid). Golay's experience with 63 applications of the test has confirmed its reliability, he declares, and shown that it is more sensitive even than the Wassermann test, while the technic is extremely simple. It was positive in 41 cases, negative in 11; parallel Wassermann tests were positive in only 37 and negative in 26.

50. **Stenosis of the Pylorus with Hypertrophy in Infants.**—The infants were breast-fed in Exchaquet's five cases, and the persistent vomiting began during the first, second, third, sixth or eighth week after birth. There was no inherited nervous taint evident, except in one instance the mother was known to be nervous and to have had stomach trouble. One child seemed to be thriving at first, but then began to vomit, and the physician the third week stopped the breast feeding and put the child on Vichy water and gruel. The vomiting kept up for a month and then stopped and extreme dropsy developed, with subnormal temperature. The diagnosis was athrepsia with idiopathic edema. This diagnosis was correct, but the primary cause, the stenosis of the pylorus, was overlooked and also the secondary cause, namely, the feeding with a mineral water and starch gruel which directly induced the dropsy, fluids being retained to dilute the salt and other minerals being taken in excess. Change to a cream-albumin diet was followed by improvement for a week, but then the child died. Nothing abnormal was found at necropsy except the hypertrophied pylorus, which had enlarged until it was scarcely permeable for fluids.

The persisting vomiting, coming on late after a feeding, extremely copious and squirting with force, the waves of peristalsis in the stomach or its total rigid contraction, and palpation of a tumor in the pylorus region are the main signs of the trouble. A tumor was evident in only two of his five cases. Castor oil, Vichy water, etc., will not stop the vomiting until the child gets too weak to vomit. A rapid drop in the weight, 500 gm. in two days in one of his cases, and in one of Tixier's, aids in the diagnosis. In well-to-do circles, where the child can have careful attendance, medical treatment may be given a thorough trial, but among the poor, the indications for surgical treatment should be broadened. The operation should come within a day or two if there is a very great drop in weight, and not later than eight or ten days if there is no improvement under systematic medical treatment. Fredet, Scudder and Munro have successfully operated for it on children only 13 to 30 days old. Breast-fed infants should be allowed to nurse as much as they will, if they vomit afterward; the peristalsis should be soothed by moist heat to the region and a little opium or atropin by the rectum. This is Heubner's expectant method. For bottle-fed children, the food should be the most easily digested, buttermilk or sweetened skim milk, milk with malted gruel or milk with albumin and cream. The child should be fed with minute amounts at a time to ward off vomiting, and the stomach should be washed out to bring away any residue. The tendency to spasm should be combated by moist heat and rectal injection of valerian, opium or atropin. The general health should be sustained by subcutaneous and rectal injection of salt solution and nutrient enemas. When possible, it may be wise to supplement the above by stretching the pylorus by intubation according to Hess' technic.

55 Comparative Study of Action of Inorganic and "Organic" Calcium-Phosphorus Preparations on the Metabolism in Recent and in Subsiding Rachitis. (Kalkphosphorpraparate.) E. Schloss.

52. **The Parathyroid Glands.**—Thimm examined the parathyroids in 100 cadavers of persons over 20 or under 2 and in sections from the throat of several fetuses, and of a large number of laboratory and zoological garden animals. Welsh's four types of parathyroids seem to correspond, he thinks, to declining glandular function, the last stage being accompanied by a colloidal secretion. The findings in this extensive material are described in detail, and especially the fetal and the atypical glands.

53. **Psychic Suppression of Gastric Secretion in Children.**—The psychogenous anomalies in gastric secretion to which Wegener refers are generally of the anachlorhydria type, but hyperchlorhydria is also encountered occasionally. There is generally an unstable nervous system and sometimes signs of the exudative diathesis. He remarks that stomach disturbances in general are unusually prevalent in his district (Mecklenburg). His patients at Rostock in describing their symptoms with almost every kind of affection invariably mention disturbance in the stomach as the main trouble. That the child refuses food is almost invariably the only symptom noticed and mentioned by the family, even when a febrile child with pneumonia or diphtheria is brought for treatment. It is now his routine practice to examine the stomach content after a test breakfast whenever there is complaint of loss of appetite and pain in the stomach. In 80 thus examined there was pronounced hyperacidity in 2 and anacidity in 17. One boy of 11 who had intense hyperacidity had been under treatment for some years for supra-orbital neuralgia, and had also astigmatism and enlarged tonsils, but no appreciable gastro-intestinal disturbances. In the other case the hyperacidity was accompanied with hypersecretion, pains and tenderness in the stomach region. The nervous origin of the secretory disturbance was evident from other signs of excessive irritability of the nervous system and also by the restoration of anachlorhydria to normal under administration of a few drops of hydrochloric acid supplementary to the impression made on the susceptible children by the introduction of the stomach tube and siphoning out of the stomach contents. Only one case proved refractory, and this was an only child of 5 whose mother was extremely neuropathic.

60 Physiologic and Therapeutic Action of Extract of Duodenal Mucosa: Sekretin. H. R. Harrower.

57. **Dry Test for Occult Blood in the Stools.**—Wagner calls attention to his simplification of the benzidin technic as extremely rapid, reliable and cleanly. A scrap of the stool is taken up on the end of a match and smeared thin on a slide. Then the usual Schlesinger-Holt-Adler reagent is poured over the slide, and in case there is blood present a blue tint develops promptly. The reagent is a knife-tip of benzidin on which is poured 2 c.c. of glacial acetic acid and 20 drops of a 3 per cent. solution of hydrogen peroxid. He calls this the dry benzidin or slide test, and says that with it there is no need to soil the fingers. The outcome is never dubious, as there is either no change to blue or it is pronounced. With a large proportion of blood the reaction occurs instantaneously.

59. **Putrefaction in the Intestines.**—In this second instalment of his report on his research in this line, Rodella asserts that his hundreds of experiments have conclusively demonstrated that putrefaction in the intestines is not so important a factor in morbidity as generally imagined. The putrefaction which is the work of ordinary saprophytic anaerobes must be regarded as a harmless process, never capable of generating pathologic products. This applies both to pure putrefaction, the work of anaerobes and the mixed process of decay. "Although putrefaction in the intestines is an entirely harmless process," he adds, "yet the gases and other irritating products generated may induce more or less serious disturbances. The harmless character of intestinal putrefaction, which was demonstrated anew in my experiments with intraperitoneal injection of guinea-pigs and rabbits, has also been rendered highly probable by the experience in recent military campaigns. Gunshot wounds of the abdomen with escape of intestine content into the abdominal cavity healed spontaneously without harm as a rule when they were left unmolested." The conception of auto-intoxication from bacterial putrefaction in the intestines is not sustained by his research. The products of putrefaction, however, facilitate infection, and hence they should be kept down as much as possible.

Beiträge zur Klinik der Tuberkulose, Würzburg

63 *The Albumin Reaction in the Sputum. (Bedeutung der quantitativen Eiweissreaktion im Sputum tuberkuloser Individuen bezüglich der Diagnose und Prognose der Lungenerkrankung.) J.-H. Benzler.

61. **Is There a Mechanical Predisposition to Apical Disease?**—Ulrici devotes nearly fifty pages to arguments and data which disprove the assumption that the size and shape of the upper ribs and the greater or less ossification of the costal cartilages induce a predisposition to tuberculous apical processes. He gives eighteen views of the superior aperture in some of his seventy-four tuberculous patients under 30, and tabulates the details of examination of 141 persons in all.

62. **Tuberculin Treatment of Tuberculosis.**—Klein gives thirty pages of tabulated details in regard to 112 patients with pulmonary tuberculosis given a systematic course of tuberculin treatment. Slight, if any benefit was realized in the "open" cases, and in the others equally favorable results as those attained can be realized by diet and hygiene alone. The tuberculin did not prevent hemorrhages.

63. **The Albumin Reaction in the Sputum.**—Benzler examined the sputum in sixty-five cases repeatedly for albumin and found that the proportion declined as the patient improved and increased as the condition grew worse. The amount seemed to be independent of the presence and number of tubercle bacilli in the sputum, and it has nothing to do with occult blood. The albumin content sinks after an artificial pneumothorax has been induced and it can thus serve as an index for replenishing the gas.

67 Composition of the Blood and Constitution of the Child's Body in Relation to Nutrition and Weight. A. O. Karnitzky.

65. **Rupture of Tuberculous Glands Into Air Passages.**—Paunz reiterates that tuberculosis in children is most frequently localized in the tracheobronchial lymph-glands. It is almost always secondary, from a primary infection in the lungs. Sometimes the foci in the lungs are so small that they are overlooked, but they are there, showing that in the great majority of cases the infection takes place by inhalation. He discusses the cases of rupture of tuberculous glands into the trachea and bronchi that have been reported in literature, including four of his own previously published, and describes in detail four further cases of his. The symptoms of pressure on the air passages are cough and difficulty in breathing. After rupture takes place there are attacks of suffocation. There may also be unilateral dilatation of the veins of the neck and slight edema of the face from the pressure. In addition to the ordinary clinical examination for tuberculosis, Roentgen examination of the glands should be made. Another important aid in diagnosis is direct tracheobronchoscopy, but in children it is preferable to use this only as an introduction to treatment. The treatment in mild degrees of compression may be only the usual treatment of tuberculosis; sea air and heliotherapy are valuable adjuvants. Severer degrees of compression should be carefully watched on account of danger of rupture. After rupture has taken place tracheotomy should be performed at once, followed by tracheobronchoscopy from below. The caseous gland should be treated as a foreign body. The rupture at first is generally only a small one, so there is abundant time for operative treatment before suffocation is fatal or even dangerous. Among ten patients treated in this way seven have recovered and three have died. The discharge of the gland through perforation is often the last act in the spontaneous healing of tuberculosis, which is not at all unusual in children over 2 years of age, increasing with advancing age. Therefore the prognosis is not bad. Only two of these ten children showed signs of pulmonary tuberculosis later. If all cases of glandular tuberculosis were carefully followed the prognosis could be improved,

73 Suture of Tendons, Nerves, etc., in the Field. (Einige wichtige Ratschläge spezieller Art für die Wundbehandlung.) O. Nordmann.

71. **Chronic Osteomyelitis.**—In the course of this long thesis Rost states that he has succeeded in inducing a typical chronic osteomyelitis in rabbits by injecting cultures of staphylococci the virulence of which had been previously attenuated by heating. Experience with more than 200 clinical cases has demonstrated that the bactericidal properties of the serum, the opsonic index and the agglutination test have little practical value. The latter is such a sensitive reaction that any insignificant suppuration anywhere is liable to veer the reaction to positive. The antistaphylolysin reaction, on the other hand, is practical and reliable. This is based on the fact that pyogenic staphylococci produce a toxin which dissolves the red corpuscles of the rabbit. In the infected organism an antibody is generated, which inhibits this dissolving action. This test differentiates tuberculous processes from ordinary osteomyelitis, as with tuberculosis there is little or none of the antitoxin generated, even when there is mixed infection. No other staphylococcus affection induces the production of so much antitoxin as osteomyelitis, and this explains why acute osteomyelitis so rarely recurs. It passes into a chronic stage with extensive production of granulation tissue. Osteomyelitis in adults is not so rare as generally supposed; it is often mistaken for a tuberculous process. In one such case the talus and in one the fifth metatarsal bone was the seat of the trouble; in a third the sternum. In one case everything seemed to indicate a sarcoma of the tibia, but an exploratory excision revealed only inflammatory tissue, and the second Roentgen picture a year later confirmed that all the trouble was osteomyelitis with a tendency to sclerosis in a man of 46, similar in every respect to the affection described by Garrè in the young. In one case the osteomyelitis was in the head of the femur. It developed abruptly with intense pains, but all signs of inflammation and tumor had disappeared by the end of the year although of course the dislocation still persists.

Therapeutische Monatshefte, Berlin

October, XXVIII, No. 10, pp. 641-672

74. **Anesthetics.**—Kochmann writes from the Pharmacologic Institute of the University of Halle to give an oversight of the present status of prophylactic and curative analgesia. He warns that the high concentration of the drug used to inaugurate anesthesia must be reduced after a certain period or it becomes dangerous. This factor of the length of time the high concentration is given is liable to be disregarded when an apparatus is used. At the same time there are certain advantages in using an apparatus. His experimental work in this line has demonstrated, he says, that mixing chloroform and ether enhances the potency of each without increasing the toxicity. Damköhler (1913) claims that a mixture of 1 part chloroform to 6 or 7 parts ether enhances the potency fully 30 per cent. It is possible, also, that the injurious action of chloroform on the circulation is nullified by the ether. Kochmann says further that the addition of potassium sulphate to a solution of novocain or cocain enhances the potency by 75 per cent. His formula is 0.25 gm. novocain; 20 c.c. of a 2.3 per cent. solution of potassium sulphate and enough of a 0.9 per cent. solution of saline to make 100 c.c. To this he adds twelve drops of a 1 per thousand solution of epinephrin. The potassium sulphate has an opposite action with some of the other anesthetics. Gros insists that the free alkaloid base is what penetrates into the tissue from any local anesthetic, and hence the action can be enhanced by adding an alkali to the solution, preferably in the form of 0.25 gm. sodium bicarbonate added to 1 gm. novocain plus 0.5 gm. sodium chlorid, dissolved in 100 c.c. distilled water.
